#STEMCELLRESEARCH: THE ETHICAL CHALLENGES AND POLICY-MAKING OPPORTUNITIES PRESENTED BY THE USE OF SOCIAL MEDIA IN STEM CELL RESEARCH

Beth E. Roxland[1], Paul Knoepfler[2]

[1]Center for Bioethics at Hofstra University, New York, NY, United States, [2]Univ of California, Davis Sch of Medicine, Sacramento, CA, United States

Since the original derivation of human embryonic stem cells in 1998, much publicity has surrounded the field of stem cell research. In recent years, social media and Internet fora, such as Twitter, Facebook, blogs and patient advocacy and empowerment websites, have played increasingly powerful roles in shaping public perceptions of stem cell research. The unfettered use of the Internet can play both positive and negative roles, however.

Accurate reporting of important discoveries and advances can influence the public's willingness to support stem cell research, to participate in stem cell clinical trials or to be treated with stem cell-based therapies. Effective use of social media may also influence political leaders and legislative efforts, affecting the amount of funding for government-sponsored research as well as the stringency of governmental oversight of research and translational therapies. Professional societies, clinicians and individual researchers also can employ social media as part of their outreach and educational initiatives, which will likely increase in prominence as mainstream media outlets cut funding for dedicated science reporting.

The impact of social media in the stem cell field also may have negative effects. One example is the emerging trend of for-profit stem cell clinics and doctors recruiting patients on the Internet through social media - a forum that often eludes regulators and watchdog groups - by using unsubstantiated claims of efficacy and safety of stem cell products. Similarly, social media may be used to promote stem cell tourism - where patients will travel to other jurisdictions (foreign, or even domestic) that have more lenient laws and oversight of stem cell therapies - for interventions that may be ineffective at best, harmful at worst. Finally, patients (or, people posing as patients) also use social media to advocate in favor of specific for-profit clinics and challenge regulatory oversight.

People suffering from illness, who may be in a particularly vulnerable situation, often turn to the internet to educate themselves about their medical condition and available treatment therapies. Relying on social media rather than trained, unbiased, and regulated sources for information is a dangerous proposition, however. In addition to intentional deception by those who may financially profit from certain research or therapeutic endeavors, some well-meaning people who attempt to educate others via social media on an ad hoc basis may unintentionally spread misconceptions about stem cells. Further, patients often attempt directly to engage stem cell researchers or clinicians through social media, leaving the trained experts uncertain of how - or even whether - to respond.

The rapidly-evolving use of social media in the stem cell field presents ethical and legal issues that the field cannot afford to ignore. In this presentation, we discuss the moral and policy challenges presented by the use of social media as stem cell research moves from bench to bedside. We also discuss ways in which governmental entities, stem cell researchers and clinicians, and professional societies may use social media as a tool to enhance public education of the state of stem cell research, and temper the hype that has surrounded this research for well over a decade. Finally, we suggest a framework to guide the use of social media by those in the field of stem cell research.

W-1002

ETHICAL CONTROVERSY, GRADUATE EDUCATION AND THE DEVELOPMENT OF SCIENTIFIC CAREERS

Ruchir N. Karmali[1], Matthew D. Pjecha[1], **Aaron D. Levine**[2]

[A]School of Public Policy, [B]School of Public Policy, Institute of Bioengineering & Bioscience, [1]Georgia Tech, Atlanta, GA, United States

Scientific advances in diverse fields ranging from stem cell research to nanotechnology pose challenging ethical questions. At the same time efforts to strengthen and broaden the U.S. workforce in science, technology, engineering and mathematics are crucial to the long-term competitiveness of the national economy. This research examines the nexus of these two trends, assessing the extent to which and the manner by which ethical controversy affects the training of graduate students and their

transition to the scientific workforce. Insights into both the challenges and the benefits of training in an ethically contentious field are gathered through interviews with early career scientists in both stem cell science and bio-nanotechology. Participants in these wide-ranging interviews were asked to reflect on the ethics of their own research, their sense of the public perceptions of their research and the various impacts of working in areas that raised ethical concerns, for at least some people, on their research. Preliminary thematic analysis of interview transcripts revealed mismatches between scientists' perceptions of the ethics of their work and their beliefs about public perceptions. In particular, in the context of stem cell science, scientists expressed worries about animal research or human biopsies (e.g. for induced pluripotent stem cell derivation) at about the same rate as they expressed concerns about the use of embryos in research, while discussion of public perceptions of the field focused on concerns about human embryos. Scientists in contentious fields reported a range of funding challenges, some of which they attributed to ethical controversy and the resulting policy environment surrounding their field, rather than broader funding trends. Scientists also reported changing research topics or avoiding certain topics altogether due to policy concerns and frequently noted that scientists working in ethically contentious fields must navigate a complex bureaucracy to complete their work. Scientists also noted what they perceived as greater need to engage in public outreach in ethically contentious fields. The research concludes by drawing on this improved understanding of the experience of scientists in fields that raise ethical controversy to suggest strategies to strengthen graduate education in stem cell science and similar fields.

W-1003

WHAT IS THE ROLE OF REDUCED FEES IN PERSUADING IVF PATIENTS TO VOLUNTEER TO PROVIDE EGGS FOR SCNT RESEARCH?

Erica Haimes
Policy, Ethics and Life Sciences Research Centre, Newcastle University, Newcastle Upon Tyne, United Kingdom

This paper reports selected findings from a UK study investigating the question: 'Does volunteering for the 'Newcastle egg sharing for research scheme', in which IVF patients pay reduced fees when providing 50% of their fresh eggs to research, entail any social and ethical costs?'. This study fills a gap in knowledge, as there have been no previous systematic investigations of women's experiences of volunteering to provide eggs for research under such circumstances. The focus in this presentation is on women's views of the role of the reduced fees in persuading them to volunteer in the first place. This was an interview-based, interpretivist study, designed to gain understanding of the volunteers' reasoning and experiences. The main findings indicate that the interviewees' goal is to have a baby; they volunteered to provide eggs to research to gain access to cheaper treatment, in a context where private IVF fees are high and there is insufficient state funding. However, the decision to volunteer was not easy, since interviewees had to juggle a wide range of uncertainties about the consequent gains and losses, when already experiencing the uncertain world of the 'IVF rollercoaster'. Overall, interviewees welcomed the 'egg sharing' scheme, but were not volunteering entirely under circumstances of their own choosing. For example, they would prefer not to provide fresh eggs whilst going through treatment and decided not to do so, under certain circumstances. They also resisted the opportunity to provide eggs for the treatment of other couples, even though they would have paid even lower fees by so doing. Therefore, although important, reduced fees do not act as an undue inducement, persuading volunteers to act against their own interests.

W-1004

COLLABORATION IN STEM CELL RESEARCH: A PHILOSOPHICAL ACCOUNT

Melinda B. Fagan
Philosophy, Rice Univ, Houston, TX, United States

I present results of a philosophical study of stem cell research. The goal of the study was to articulate conceptual issues related to evidence, experiment, and explanation. Methods used are those of philosophy: conceptual analysis, reflection on past and contemporary cases, and logical argument. The full argument for a philosophical audience appears in a new book: Philosophy of Stem Cell Biology, Palgrave Macmillan (Jan 2013). The present study differs from the book in focus and presentation, extending the results for an audience of stem cell scientists. Here, my overall claim is that collaboration among stem cell researchers is more fundamental, and more complex, than has been explicitly recognized. I support this claim with specific case studies and arguments.
First, collaboration among laboratories using different methods is necessary to support any general claims about stem cells. This follows from the general definition of a stem cell as a cell that is capable of both self-renewal and differentiation. When precisely expressed as an abstract model, this stem cell concept is shown to depend on several parameters, differently specified by different experimental methods: a cell lineage L, time interval n, and set of variable cell characters C. To apply to biological phenomena, the key parameters must be specified. Different values of these variables correspond to different entities that can be identified as 'stem cells.' This accounts for the diversity of entities referred to as 'stem cells.' Another consequence is that claims about stem cells must be understood in terms of experimental methods used to identify them. The question then arises: how do these disparate results fit together to yield a satisfying explanation? Explanatory generalizations about stem cells, and clinical applications based thereon, require collaboration across experimental contexts.
This collaborative view of stem cell research has several important implications. One is that the distinction between 'adult' and 'embryonic' stem cell research is revealed as pernicious. Case studies of mHSC, hESC, and teratocarcinoma/EC research indicate that field as a whole progresses by multiplying models and constructing a network of comparisons among them. Though hESC research plays a pivotal role in this research network, general knowledge emerges from 'traffic' across models and new combinations of techniques. The next step forward is to unify the two main branches of stem cell biology, expanding the network of comparisons and generality of results. The 'adult/embryonic' dualism impedes this progress. Another consequence of my view is that Systems Biology (specifically, mathematical models of gene regulatory networks) has a key role to play in explanations of stem cell phenomena, as do simple abstract models like Waddington's epigenetic landscape. Thirdly, the network of stem cell models and methods is structured and unified by clinical goals, which thereby influence emerging explanations. This unifying, guiding role is analogous to fundamental theory in physics. This suggests a general standard for responsible translational research, that would be accessible to non-experts. So these philosophical arguments, though abstract, have important implications for organization of stem cell research and progress toward clinical translation.

W-1005

POLICY UNCERTAINTY, RESEARCH FUNDING AND THE CONDUCT OF STEM CELL SCIENCE

Aaron D. Levine
School of Public Policy, Institute of Bioengineering & Bioscience, Georgia Tech, Atlanta, GA, United States

Emerging technologies, such as stem cell research and nanotechnology, offer substantial promise to improve our quality of life. Yet, at the same time, many emerging technologies raise challenging ethical questions. As a result of these and other tensions, the outcomes of policy debates surrounding emerging technologies often vary both across jurisdictions and time, yielding a heterogeneous and uncertain policy environment. In this project, I consider policy uncertainty surrounding pluripotent stem cell research and assess its impact on scientists in this promising but controversial field. Drawing on data from a recent survey of stem cell scientists in the United States, I argue that policy uncertainty surrounding federal funding policies for human embryonic stem cell research has negatively impacted the development of the broader field of stem cell science, affecting not just scientists working with human embryonic stem cells, but also those working with less controversial types of stem cells. My analysis also illustrates the importance of state policy in this field. In particular, scientists in states that have provided funding for stem

cell research, including research using human embryonic stem cells, are substantially less likely than scientists in states without such funding to report impacts of policy uncertainty. This effect is present for the full sample of stem cell scientists, including both scientists working with human embryonic stem cells and other less contentious cell types, but is strongest for scientists working with human embryonic stem cells. State policies that legalize or otherwise support stem cell research, but do not provide funding have no discernible effect. Together results highlight the negative consequences of the policy uncertainly on the development of stem cell research and emphasize the importance of developing and maintaining stable funding structures in ethically contentious areas of biomedical research.

W-1007

SELF REGULATION OF AUTOLOGOUS CELL THERAPIES: A MODEL

Bernard E. Tuch, Heather Main, Dominic Wall
NSW Stem Cell Network, Sydney, Australia

Autologous cell therapies are being practised by an increasing number of clinicians internationally - for the treatment of a variety of disorders. This includes rheumatological conditions where the sources of cells are the vascular stromal fraction obtained from lipoaspirates during liposuction, and platelet rich plasma obtained from peripheral blood. In Australia, oversight of these procedures by the regulatory body, the Therapeutic Goods Administration (TGA), is not required. This is because the current regulations contains a broad exemption permitting clinicians to treat their patients with autologous cells without restrictions on the extent of manipulation or whether the cells are used in a homologous manner.

Despite this lack of oversight, a number of companies carrying out autologous cell therapies have become concerned about the lack of checks and balances. End users also have their welfare to be considered. To address these concerns, the NSW Stem Cell Network held a Workshop entitled Cellular Therapies for Repair of Musculoskeletal Injuries in Sydney during October 2012. Four key companies practising autologous therapies for rheumatological conditions presented their data, as did Mesoblast, which is conducting clinical trials using allogeneic cells. A representative of the TGA spoke about the regulatory requirements, and appropriate cell manufacturing requirements were addressed by a representative of the International Society for Cellular Therapy (ISCT).

Out of the workshop came a desire for the establishment of a Steering Committee to discuss self regulation by the companies practising autologous therapies. Three teleconferences have occurred between then and the date this abstract was written in February 2013, chaired by the Director of the NSW Stem Cell Network and involving the ISCT local representative. Issues raised and agreed to have been (a) the need for the development of evidence based medicine; (b) ensuring fully informed consent is obtained; (c) manufacturing the autologous product to be injected into the patient using internationally accepted standards, such as those produced by the Foundation for the Accreditation of Cellular Therapy; (d) following the advertising standards set by the Australian Health Practitioner Regulation Agency.

To cement these agreed-to standards into practice, it has now been decided by the members of the Steering Committee to create a written Code of Conduct. It is anticipated that this Code of Conduct will include the mechanisms of implementing the necessary checks and balances to provide guidance to its users, as well as independently monitoring the practices being followed. The input of consumers also will be needed.

Whilst there is much work to be done in the creation and implementation of the Code of Conduct, it represents a step in the necessary direction to ensure high standards of health care are maintained in a field with a low level of government regulation. Self regulation is possible in this industry, just as it is practised in many others, for example, Medicines Australia to some extent regulates how pharmaceutical companies operate in our country.

ADAM10 AND ADAM17 INCREASE MIGRATION OF GLIOBLASTOMA STEM PROGENITOR CELLS

Elodie J. Siney, Gareth J. Thomas, **Sandrine Willaime-Morawek**
Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Glioblastoma (GBM) is the most aggressive form of malignant brain tumour, with a mean survival of just over one year. High recurrence rates after surgical resection and ineffectiveness of chemotherapy have suggested a role for brain tumour stem cells (BTSCs) in producing resistance to therapy. To improve this poor prognosis there is a need to develop new adjuvant therapies to slow disease progression, specifically reducing the invasion of neoplastic cells into healthy brain tissue. Due to their role in tissue remodelling, members of *A D*isintegrin *A*nd *M*etalloproteinase (ADAM) family have been implicated in the etiology of solid tumours including breast, colon and glioma, where reports of overexpression of ADAM10 and 17 have prompted further investigation into the role of the proteins in glioma biology, tumourigenicity and invasion. We previously showed that ADAM10 and 17 are overexpressed in glioblastoma and promote BTSCs stemness properties by supporting their self-renewal. We now examine the effect of ADAM inhibition on GBM stem/progenitor cell migration and differentiation *in vitro*. Here we report that inhibition of ADAM10 and 17 increases glioma cell migration towards a mix of growth factors, including epidermal growth factor and basic fibroblastic growth factor. Migrated BTSCs exhibited decreased stem cell/progenitor markers (Nestin and CD133), but increased neuronal lineage marker (beta-III-tubulin) expression compared to non-migrated cells suggesting that migrated cells are more differentiated.
Using a 3D *in vitro* model, we also showed that ADAM10 and 17 inhibition promotes migration of cells out of the tumourspheres. Surprisingly, in this model, the migrated cells seems less differentiated, showing an increase of nestin expression and a decrease of beta-III-tubulin expression, compared to cells closer to the centre of the spheres. These results suggest a role for ADAMs in maintaining a BTSC phenotype and give insight into possible therapies that target the invading GBM cells.

SIGNALS OF CD44/HYALURONAN PROMOTES HEPATOCELLULAR CARCINOMA STEM CELL PROLIFERATION AND PRODUCTION OF ALPHA FETOPROTEIN IN VITRO

Hsiao-Nan Hao[1], Qingbao Wang[2], Jean Peduzzi[1], Peter Hao[1], Deqi Xiang[3]
[1]Wayne State University, Detroit, MI, United States, [2]surgery, Taian medical college, Taian, Shandong, China, [3]Xiamen Neocell Biotech, Xieman, China

Introduction: Cancer stem cells (CSC) have recently been proposed to be cancer initiating cells responsible for tumorigenesis and contributing to cancer resistance. CSCs have been considered to be a cardinal cellular target for cancer chemotherapy because a single CSC plays a critical role in generating malignant tumors under certain circumstances. CSCs share many of cell biological characteristics with non-cancer stem cells such as self-renewal and proliferation as well as differentiation. Hepatocellular carcinoma is a solid common malignant tumor arising from the hepatocytes in liver tissue. Many reported results have shown that hepatoblastoma stained heterogeneously. However, among the cancer tissue cell isolates, a small population of cells interacts positively with stem cell makers such as CD34 and CD44. Those cells were also strongly stained with a-fetoprotein. The CD44/hyaluronan molecules on the surface of CSC have been found to play important roles on tumor initiation, proliferation, metastasis as well as tumor invasion induced inflammation. In this study, we have characterized the expression of the CD44/hyaluronan on the isolate liver cancer cells. Enriched CD44/hyaluronan expressed on and in the surface membrane and cytosol specifically in vitro. The results of this study also demonstrate that the a-fetoprotein production of CSC highly associate with CD44 expression. Lower levels of CD44/hyaluronan is unlikely to up-regulate the CSC to express a-fetoprotein, whereas, high levels of CD44/hyaluronan affects a-fetoprotein strongly. Data from in vitro studies have shown that enhancement of CD44 on the surface occurs only in the cells with CD34/CD44 dual expression.

This experimental result provides a new methodology to identify and isolate CSC from hepatoblastoma surgical specimens. However, the mechanism of CD44 to regulate alpha fetoprotein expression in the population of CSC-like cells needs further studies.
Experimental Results: This study focused on a methodology to identify and isolate CSC from of hepatoblastoma surgical specimens. Viable cells of hepatoblastoma were incubated with specified MEM culture medium. CD34, CD44, hyaluronan, keratin AE1/AE3, CAM5, CK7, CEA and alpha fetoprotein were analyzed using immunocytochemical and laser scanning microscope. The percentage of CSC was estimated. Overall, about 5% to 8% cells (from 22 clinical specimens) were defined to be CSC according to the stem cell specific makers. The gene expression profile of CSC was also analyzed use cDNA microarray representing 11000 mRNAs. Membrane and cytosolic protein were analyzed use western blotting and flow cytometer. Endosomal CD44 and hyaluronan were also estimated. The results indicate that non-CSC can cells show a lack of evidence to have CD34/CD44/hyaluronan involved although it is likely to produce detectable amount alpha fetoprotein. The in vitro results have shown that increasing alpha fetoprotein expression significantly follows elevated the levels of CD44/ hyaluronan.
Material Methods: This is an on-going CSC research project that was authorized by university HIC. Cancer cells were isolated from surgical specimens after pathology diagnosis. The human fetal liver cell primary cultures were used for alpha fetoprotein production control. The viability of all cell isolates is more than 90% used for this study. CSC mRNA profiling was analyzed use micro-array. The intracellular levels of alpha fetoprotein and CEA were estimated use ELISA.

W-1013

THE MET ONCOGENE IS A FUNCTIONAL MARKER OF A GLIOBLASTOMA STEM CELL SUBTYPE AND A THERAPEUTICAL TARGET FOR RADIOSENSITIZATION

Carla Boccaccio[1], Francesca De Bacco[1], Elena Casanova[1], Enzo Medico[1], Serena Pellegatta[2], Francesca Orzan[1], Raffaella Albano[1], Paolo Luraghi[1], Antonio D'Ambrosio[1], Bianca Pollo[2], Paolo M. Comoglio[1], Gaetano Finocchiaro[2]
[1]Institute for Cancer Research, Candiolo, Italy, [2]Fondazione IRCCS-Istituto Neurologico C. Besta, Milano, Italy

The existence of treatment-resistant cancer stem cells contributes to the aggressive phenotype of glioblastoma. However, the molecular mechanisms that sustain stem cell proliferation in these tumors are largely unknown. We report that expression of the MET oncogene, encoding Hepatocyte Growth Factor (HGF) Receptor, identifies a subset of glioblastoma-derived neurospheres (MET-pos-NS), characterized by distinctive genetic and molecular features such as: (i) normal EGF Receptor gene copy number; (ii) inactivation of the tumour suppressor gene PTEN; (iii) gene expression profile classified as “mesenchymal” or “proneural”. Conversely, neurospheres that do not express MET (MET-neg-NS) usually display complementary features such as: (i) EGF Receptor gene amplification; (ii) intact PTEN gene; (iii) gene expression profile defined as “classical”. We show that MET-pos-NS are endowed with a hierarchical organization, including a cell subpopulation expressing high levels of MET (MET-high) at the top, and a cell subpopulation that conversely express negligible levels of MET (MET-low), at the base. This conclusion is supported by data showing that, upon isolation from neurospheres, (i) MET-high, but not MET-low cells, retain long-term propagation and multi-potential differentiation; (ii) MET-high, but not MET-low cells, can regenerate a mixed MET-high/MET-low cell population; (iii) MET-high display increased tumorigenic ability as compared to MET-low cells, and are the only that form tumors containing both MET-high and MET-low cells. In MET-high cells, we find also that HGF sustains proliferation, clonogenicity, expression of self-renewal markers, migration, and invasion in vitro. Finally, we show that MET-high cells are more radioresistant than MET-neg cells, and are dramatically radiosensitized by treatment with specific MET inhibitors. Together, these findings suggest that MET is a functional marker of glioblastoma stem cells, and a promising target for identification and therapy of a subset of glioblastomas.

W-1014

MESENCHYMAL TRANSFORMATION OF GLIOMA STEM CELLS IS REGULATED BY THE ALDEHYDE DEHYDROGENASE 1A3-MIR99B/LET7E/125A SIGNALING IN A C/EBPB-DEPENDENT MANNER

Sunghak Kim[1], Ping Mao[1], Kaushal Joshi[1], Jianfeng Li[2], Lucas Santana-Santos[3], Uma R. Chandran[3], Panayiotis Benos[3], Luke Smith[1], Mao Dewang[4], Bo Hu[5], Shi-Yuan Cheng[5], Robert W. Sobol[3], ichiro Nakano[1]

[1]Ohio State University, Columbus, OH, United States, [2]University of Pittsburge, Pittsburgh, PA, United States, [3]University of Pittsburgh, Pittsburgh, PA, United States, [4]Xi'an Jiaotong University, Xi'an, China, [5]Northwestern University, Chicago, IL, United States

High-grade glioma (HGG) tumors are composed of heterogenous tumor cell populations including tumor cells with stem cell properties termed glioma initiating/propagating cells or glioma stem cells (GSCs). Here we present data describing the presence of two distinct GSC subtypes, termed as Proneural (PN) and Mesenchymal (MES) GSCs, in HGGs based upon genome-wide transcriptome microarray analysis and microRNA profiling. Similar to the clinical feature, MES GSCs display more aggressive and radioresistant phenotype than PN GSCs. Intriguingly, PN GSCs acquire MES signature when they are treated with radiation, suggesting the PN-to-MES transition (PMT) of GSCs. Pathway analysis of the array data identified aldehyde dehydrogenase 1A3 (ALDH1A3)-mediated pathway as the most upregulated pathway in MES GSCs over PN GSCs. Mechanistically, ALDH1A3 is regulated by the oncogenic transcription factor C/EBPβ by both directly through the binding to the ALDH1A3 promoter and indirectly through regulation of the evolutionary conserved miR cluster containing miR-99b, let-7e, and miR-125a. Physiologically, forced expression of miR-99b-let7e-125a cluster in the MES GSCs leads to the loss of mesenchymal phenotypes and sensitizes MES GSCs to irradiation. Collectively, the C/EBPβ-miR cluster-ALDH1A3 axis plays a critical role in GSC evolution to gain therapy-refractory mesenchymal phenotype.

W-1015

ROLE OF PRION PROTEIN AND STRESS INDUCIBLE PROTEIN ONE INTERACTION IN THE BIOLOGY OF GLIOBLASTOMA STEM CELLS

Rebeca P. Iglesia[1], Tiago G. dos Santos[2], Vilma R. Martins[2], Marilene H. Lopes[1]

[1]Department of Cell Biology and Development, Institute of Biomedical Sciences, São Paulo, Brazil, [2]Laboratory of Cellular and Molecular Biology, A.C. Camargo Hospital, São Paulo, Brazil

Glioblastomas (GBM) are highly lethal brain tumors, which contains a subpopulation of glioblastoma stem cells (GSC) capable of promoting tumor angiogenesis, invasion and radiotherapy and chemotherapy resistance, contributing to the failure to treat these cancers. Studies show that the interaction of two proteins, the cellular prion protein (PrPC) and stress inducible protein 1 (STI1), promote proliferation of GBM and recent data from our group indicate that the blocking of the PrPC-STI1 interaction may have therapeutic potential. Both PrPC and STI1 are highly expressed in the CNS. Their interaction modulates processes involved in neural plasticity and plays an important role in the biology of neural stem cells (NSC), promoting proliferation and self-renewal. Based on these data, this study aims to evaluate the role of PrPC-STI1 interaction in the biology of GSC. Our data suggest that the PrPC-STI1 interaction is involved in GSC self-renewal and proliferation, in which the addition of STI1 in culture medium in clonal density and BrdU incorporation assays seems to promote dose-dependent proliferation in GBM human strain. However, PrPC-nonexpressing cells didn’t show response to treatment with STI1, suggesting that the proliferative effect is dependent on interaction with PrPC. The elucidation of mechanisms controlling GSC proliferation is necessary to identify relevant targets for therapeutic intervention, increasing the effectiveness of treatment through the targeting of GSC, decreasing tumor invasion, proliferation, and even the recurrence of this tumor.

W-1016

EVOLUTION OF CANCER STEM CELLS IN GLIOMA TO PROMOTE THEIR THERAPY RESISTANT PHENOTYPE

Ichiro Nakano

Neurological Surgery, The Ohio State University, Columbus, OH, United States

EVOLUTION OF CANCER STEM CELLS IN GLIOMA TO PROMOTE THEIR THERAPY RESISTANT PHENOTYPE

High grade glioma (HGG) is a life-threatening brain tumor. Recurrence is inevitable in virtually all cases and a permanent cure for HGGs remains elusive. Among heterogeneous tumor cells, glioma stem cells (GSCs) are defined as a subpopulation resistant to chemo- and radiotherapy with prominent tumorigenic ability. Identification of novel therapeutics designed to target the GSC population in HGGs has emerged as an attractive strategy to overcome this lethal disease. The recent genome-wide transcriptome analysis identified 3 subtypes, proneural (PN), proliferative, and mesenchymal (MES), in HGGs. These HGG subtypes harbor distinct gene signatures and altered signaling pathways with some clinical relevance. During malignant transformation, HGGs appear to gain therapy resistance, at least in part, through their phenotypic drift into mesenchymal tumors. In addition, some of the current therapies, if not all, appear to induce mesenchymal transformation of HGGs resulting in more therapy-resistant tumors. Nonetheless, identification of subtype-specific GSCs remains elusive.
My lab recently identified clinical HGG sample-derived two mutually-exclusive GSCs: proneural (PN) and mesenchymal (MES) with striking phenotypic differences with clinical relevance. Transcritpome microarray analysis, miRNA profiling, and subsequent functional analysis demonstrated that distinct signaling pathways regulate tumorigenesis and propagation of the individual GSC subtypes. For example, PN GSCs are dependent on the oncogenic transcription factor c-Myb (Miyazaki et al., Clinical Cancer Res. 2012, and unpublished data) and MES GSCs are dependent on the oncogene/mitotic kinase MELK and Survivin (Guvenc et al., Clinical Cancer Res. 2012; Gu et al., Stem Cells 2013; Joshi et al., Stem Cells 2013). Intriguingly, upon radiation treatment, PN GSCs gain the phenotypes of MES GSCs (PN-to-MES transformation; PMT), which are much more aggressive and radioresistant than original PN GSCs. Of note, targeting the MES-specific pathways partially blocks PMT of GSCs. These results may partly explain the molecular mechanisms underlying mesenchymal transformation of HGGs to promote therapy resistance. Here I summarize our latest data to elucidate the molecular mechanisms that drive GSC evolution to promote their therapy resistant phenotype.

W-1017

THE SEMAPHORIN 3A-NEUROPILIN-1 SIGNALING PROMOTES CLONOGENIC GROWTH OF GLIOMA STEM CELLS VIA ACTIVATION OF TGFβ SIGNALING.

Dong-Hun Woo[1], Nakho Chang[2], Eunhee Kim[1], Jeremy Rich[1], Do-Hyun Nam[2], Jeongwu Lee[1]
[1]Department of Stem Cell Biology and Regenerative Medicine, Lerner Research Institute, Cleveland Clinic, Cleveland, OH, United States, [2]Cancer Stem Cell Research Center, Samsung Biomedical Research Institute, Seoul, Korea, Republic of

Glioblastoma multiforme (GBM) harbors highly tumorigenic, stem-like cells (GBM stem/propagating cells, GSCs) that are implicated in GBM progression and recurrence. Through in vitro clonogenic growth-based screening assays, we have identified Semaphorin 3A (Sema3A) as a potent mitogen for GSCs. Sema3A, generally known as an axon guidance molecule, promotes proliferation and clonogenic growth of GBM cells by binding to its receptor Neuropilin-1 (NRP1). The Sema3A-NRP1 interaction induces phosphorylation of SMAD2 and activates the Transforming growth factor β (TGFβ) signaling, a positive GSC regulator. Freshly isolated patient-derived GBM cells that express high levels of NRP1 proteins are highly clonogenic compared to bulk tumor cells, and enriched with the activated TGFβ signaling pathway. NRP1 inhibition by short hairpin RNA-mediated knockdown or treatment with NRP1 blocking antibodies decreased TGFβ pathway activity and stem cell marker expression in GSCs. Finally, NRP1 knockdown decreased clonogenic growth of GBM cells and prolonged the survival of mice in an orthotopic xenograft tumor model. Together, these data suggest that the Sema3A-NRP1-TGFβ signaling axis is a critical regulator of GSC maintenance and a potential therapeutic target for GBM.

W-1018

S100A4 EXPRESSION AND FUNCTION IN GBM STEM CELLS

Kin-Hoe Chow, Hee Jung Park, Kyuson Yun
Research: Kyuson Yun's lab, The Jackson Laboratory, Bar Harbor, ME, United States

The ineffectiveness of current treatment for the most aggressive form of adult brain tumor, *Glioblastoma multiforme* (GBM), demands novel therapeutic approaches. One such approach may be targeting cancer stem cells (CSCs: a sub-population of cancer cells with defining characteristics of stem cell and the unique ability to initiate a tumor upon transplantation). CSCs have been shown to be more therapy-resistant and have the ability to generate recurring tumors. Unfortunately, the number of known markers and regulators of GBM stem cells is limited currently. Through comparative gene expression analysis of FACS-sorted populations of cells from a mouse GBM model, our laboratory has previously identified 45 genes that show differential expression patterns in GBM stem cells. Here, we focus on analyzing one of these genes, *S100a4*, and provide evidence that *S100a4* is a novel regulator of glioma stem cells. Analysis of mouse GBM tumor tissues confirmed that only a small number of tumor cells express high levels of S100a4, implying that S100a4 could be a candidate marker for CSCs. Using primary tumor cells isolated from S100ß-verbB;p53 gliomas, we found that S100a4^{hi} cells are enriched with self-renewing, sphere-forming cells. In addition, orthotopic injection of S100a4^{hi} and S100a4^{lo} cells from the same tumor showed that mice injected with S100a4^{hi} cells had significantly shorter survival time, supporting the idea that S100a4^{hi} cells are enriched with CSCs. Consistently, when S100a4+ cell were depleted in primary GBM tumorsphere cultures, numbers of self-renewing cells were significantly reduced. Furthermore, when S100a4^{hi} cells were ablated *ex vivo* prior to intracranial injection, mice injected with S100a4^{hi}-depleted cultures survived significantly longer than mice injected with control treated cells. Altogether, these studies strongly support our original hypothesis that S100a4^{hi} cells are enriched with CSCs. Suggestive of conserved function and expression in human GBMs, analysis of a human glioma database (Rembrandt) revealed a significant correlation between *S100A4* expression level and patient survival time. Results from on-going experiments with patient-derived GBM stem cells suggest that *S100A4* is critical for proliferation and self-renewal of human GBM tumorsphere cells *ex vivo*. Collectively, our studies strongly suggest that *S100a4* is a potential regulator and a marker for GBM stem cells in human and mouse tumors.

BMP INHIBITORS REGULATE THE DIFFERENTIATION/SELF-RENEWAL AXIS IN GLIOMA STEM CELLS

Kenneth Yan, Anita Hjelmeland, Jeremy Rich
Stem Cell Biology & Regenerative Medicine, Cleveland Clinic, Cleveland, OH, United States

Contributing to the tumorigenicity of glioblastoma are glioma stem cells (GSCs), a population of cells within a given tumor that can propagate heterogeneous tumors and are capable of extensive self-renewal. These cells are known to confer resistance to traditional chemo- and radiotherapies, and so there are hopes that further characterization of these cells will lead to the development of GSC-specific approaches to therapy in the future. Bone morphogenetic proteins (BMPs) are thought to be one potential GSC-specific therapy that will promote GSC differentiation toward an astrocytic lineage and attenuate tumor growth. In designing therapies, however, it is also important to consider secreted microenvironmental cues that may play a major role in tumor growth. These cues are provided within GSC niches by the GSCs themselves or by supporting cells such as tumor-associated microglia or endothelial cells. I have recently identified BMP regulators as potential secreted cues to maintain GSCs. My data demonstrate that these regulators are elevated in the GSC population compared to non-stem glioma cells. I have also found that recombinant forms of these proteins antagonize the effects of exogenous BMP. Furthermore, expression of these proteins correlates with patient survival in certain glioma subtypes. Together, these data suggest that these BMP regulators might be secreted within GSC niches in gliomas, limiting the utility of BMP as a treatment while providing new avenues for targeted therapies.

GLIOMA STEM CELL - ENDOTHELIAL CELL NICHE INTERACTIONS DEFINE MALIGNANT PROGRESSION IN GLIOBLASTOMA

Anjali Shiras, Aman Sharma
National Centre for Cell Science, Maharashtra, India

Glioblastoma multiform (GBM) is a highly heterogeneous, vascularized tumor exhibiting hierarchical organization and replete with a distinct glioma stem cell (GSC) population that drives tumor growth, progression and therapeutic resistance. With an aim to identify origin of the self-renewing glioma stem cell population, we developed several *in vitro* model systems that mimic phenomena of malignant tumor progression in GBM. Further, we explored glioma stem cells developed as free floating neurospheres to study mutual interactions with the vascular niche micro-environment that is mainly comprised of endothelial cells (EC) and the perivascular niche components of extracellular matrix. For this, we generated *in vitro* co-culture systems comprising of GSCs and Endothelial cells (EC). We specifically focused on investigating interactions of GSCs with perivascular niche endothelial cells under both two-dimensional and three dimensional growth conditions. Recent reports have shown prominence of ECs in regulation of GSC, however, almost all studies have used either HUVEC or other types of non-tumor derived endothelial cultures. To mimic a more functional vascular niche for GSC and to understand mutual niche specific signalling mechanisms for GSC phenotype maintenance and GSC
driven angiogenesis response in ECs, we independently generated GSC and EC cultures from the same glioma tumor. We differentially labeled GSC and EC cultures with green and red PKH dyes and established GFP/RFP labeled GSC/EC co-culture systems and used them to analyze effects on cell proliferation and angiogenesis using flow cytometry, matrigel tube formation and *in vitro* 3D sprouting angiogenesis assays. GSCs mutually grown with ECs induced enhanced proliferation, migration and contributed towards accelerated tumorigenicity of GSCs, compared to GSC alone. Characteristically, their niche specific mutual interactions induced activation of PDGF signalling and contributed to enhanced proliferation and migration of either cell types in a 3D co-culture assay. Further, we showed that tumor derived endothelial cell population differed significantly from the non-tumor endothelial cells and showed auto-activation of angiogenesis pathways. Interestingly, in PKH labeled co-culture assay, the presence of dual labeled cell population of GSC-EC suggested towards activation of novel niche specific signalling mechanisms mediated by circulating microvesicles**.** We propose that targeting glioma stem cell niche may act as double edge sword and not only curb GSC growth but also inhibit
GSC induced angiogenesis thereby providing novel therapeutic approaches in glioma treatment.

W-1023

DOPAMINE RECEPTOR ANTAGONISTS SELECTIVELY TARGETS THE GROWTH OF GLIOBLASTOMA STEM CELLS.

Sonam Dolma[1], Milly So[2], Ian Clarke[2], Peter Dirks[2]

[1]Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [2]Development and Stem Cell, The Hospital for Sick Children, Toronto, ON, Canada

Glioblastoma multiforme (GBM) is the most common malignant primary brain tumor that has very poor prognosis. Its growth is driven by cancer stem cell that has the potential to initiate and maintain the tumor. Targeting the cancer stem cell pool provides a novel approaches in treating glioblastoma. Therefore, understanding the regulatory network that governs the growth of glioblastoma stem cells is pivotal in controlling the tumor. We employed small molecule approach to probe the glioblastoma stem cell network. A previous screen in our lab showed a hit enrichment of neurotransmitter compounds when we screened unbiased bioactive library in mouse neural stem cells, therefore probing glioblastoma stem cells with neurotransmitter modulators is predicted to reveal novel targets. We interrogated all classes of neurotransmitters modulators containing 680 compounds in a series of glioblastoma neural stem cell lines (GNSC), human fetal neural stem cell lines (hfNSC) and BJ fibroblasts as a control. This screening approach allowed us to identify compounds that selectively inhibit the growth of GNSC and hfNSC. The primary screen identified 29 compounds that selectively inhibit the growth of hfNSC and GNSC when compared to BJ fibroblast at a screening concentration of 5uM. Further retesting at various doses validated 10 compounds that showed more than 8 fold selectivity. Compounds modulating dopaminergic, serotonergic and cholinergic pathways are enriched in hits suggesting a plausible role in neural stem cell network. Three out of ten compounds showed 2-6 fold more selective towards GNSC when compared to hfNSC and two of these compounds are dopamine receptor antagonists. In vivo validation of dopamine receptor antagonists in subcutaneous implanted tumor in NOD SCID gamma mouse showed 40% reduction in tumor mass. Furthermore, treated tumors have reduced clonogenic potential when compared to control by in vitro limiting dilution assay. This preliminary data suggests that dopam-

ine receptor antagonist reduces the tumor size by depleting the cancer stem cell pool. To further characterize the mechanism, we first confirmed the expression of dopamine receptor in hfNSC and GNSC lines. The preliminary knockdown experiment suggests that dopamine receptor inhibits the growth of GNSC. To elucidate the mechanism that confers GNSC selectivity, we performed phospho kinase profiling of 43 kinases. Interestingly, we observed differential response of GNSC and hfNSC towards dopamine receptor antagonists. The dopamine receptor antagonist decreases the phosphorylation of ERK1/2, Akt, TOR and p70S6 kinase in GNSC while there is no dramatic change in hfNSC. Dopamine receptors are known to activate ERK1/2 signaling. Selectivity of GNSC towards dopamine receptor antagonist may be partly conferred through ERK1/2 pathway, which is deregulated in glioblastoma.
In conclusion, we identified dopamine receptor antagonists that selectively inhibit the growth of glioblastoma stem cells both in vitro and in vivo. This selectivity may be partly conferred through ERK1/2 pathway, which is deregulated in GNSC or could be at receptor level with differential regulation or activity of dopamine receptors, which we are in process of studying. Dopamine receptor antagonist could potentially serve as a therapeutic agent in treating glioblastoma.

TARGETING SELF-RENEWAL IN BRAIN TUMOR

Zhe Zhu[1], Muhammad Amir Khan[1], Jan Gronych[2], Olga Bernhardt[1], Andrey Korshunov[3], Bernhard Radlwimmer[2], Peter Lichter[2], Haikun Liu[1]
[A]Normal and Neoplastic CNS Stem Cells, [B]Division of Molecular Genetics, [C]Department of Neuropathology, [1]DKFZ, Heidelberg, Germany

Cancer stem cells (CSCs) have been suggested as potential therapeutic targets for treating malignant tumors, but the in vivo evidence supporting that is still in debate.
Here we established a mouse model that allows stem cell-specific gene targeting in unperturbed high-grade mouse brain tumor. Using a GFP reporter driven by the promoter of the nuclear receptor tailless (Tlx) in the transgenic mouse model, a neural stem cells (NSCs) specific transcription factor, we demonstrate that Tlx positive cells of primary brain tumors are mostly quiescent and they are strong candidates for brain tumor stem cells (BTSCs). After introducing a BTSC-specific knock-out of the tailless gene in primary mouse tumors, we observed a loss of self-renewal of BTSCs, which leads to significant prolongation of animal survival. Furthermore, we demonstrate that loss of Tlx in BTSCs leads to the induction of essential pathways mediating cell cycle arrest, cell death and neural differentiation. Additionally we show that Tlx is a prognostic marker in human high-grade brain tumors for worse survival.
Our study provides the first genetic evidence for targeting self-renewal pathway in established primary tumors and proves that BTSCs are suitable therapeutic targets, thus strongly supporting the CSCs hypothesis and the importance of therapeutic approaches targeting CSCs.

POWER LAW GROWTH IN THE SELFRENEWAL OF HETEROGENEOUS GLIOMA STEM CELL POPULATION

Michiya Sugimori, YUMIKO HAYAKAWA, SATOSHI KURODA
Univ of Toyama/ Graduate School of Medicine and Pharmaceutical Sciences, Toyama, Japan

Cancer survives via recapitulation of cancer cell population beyond generations. Cancer stem cells (CSCs), which would be involved in the recapitulation process, exhibit heterogeneity resulting in a tumor development of a diverse cancer cell population. However, it still remains unclear whether and how CSC heterogeneity is maintained during tumor development. We employed a tumor neurosphere culture, where glioma stem cells undergo self-renewal and form clonal spheres while maintaining undifferentiated states in the methylcellulose containing medium. This study revealed, in detail, the self-renewal process of U87 human glioblastoma cell line derived glioma stem cell-like cell (GSCC) clones. The frequency distribution of cell number per clone, where the GSCC clones grew diversely, exhibited power-law pattern. Six repeated passage experiments suggested that diversity and power-law

in growth of GSCCs recapitulated beyond generations. Size-based fractionation experiments further showed that both small- and large-clone derived population regenerated populations following power-law pattern and the diversity in growth. These suggest a scale- and space-free code where heterogeneous GSCCs flexibly and reversibly change the growth traits. Thus, cancer repopulates beyond generations while maintaining CSC heterogeneity. Such plastic repopulation activity is involved in cancer exacerbation via metastasis and recurrence after radiation and chemotherapy. This study definitely suggests the importance of a power-law code in the CSC plasticity as a potential therapeutic target in cancer.

ADDRESSING THE MECHANISMS OF TUMOR-TROPIC MIGRATION OF NEURAL STEM CELLS

Merve Karabörk, Tugba Bagci-Onder
School of Medicine, Koç University, Istanbul, Turkey

In addition to their applications in regenerative medicine, neural stem cells (NSCs) have recently been recognized as efficient delivery vehicles for therapeutics in a number of malignancies including brain tumors. The NSCs utilized in preclinical brain tumor models have been derived from various sources, mainly fetal CNS tissues and recently from differentiated from embryonic stem (ES) cells. While tumor-tropism of most NSC lines has been well documented, the mechanisms and the major molecules involved in such migratory behavior have been largely unexplored. To address these questions, in this study, we have compared the tumor-directed migration abilities of different NSC lines and characterized the molecular differences between the “highly migratory” and “stationary” NSCs. We have assessed the gene expression levels of cell motility genes (e.g. Rho family GTPases, cytoskeletal regulatory proteins, focal adhesion kinases), extracellular matrix and adhesion molecules (e.g. collagens, ECM proteases, integrins) and chemokine signaling components (e.g. chemokine receptors) in these cells. This survey yielded a number of candidate pathways that were highly active in the “highly migratory” NSCs. Exogenous activation of a subset of these pathways increased the migratory ability of stationary NSC lines. Our study provides a “tumor-tropism” signature of the NSCs and identifies key signaling molecules that can be exploited to further increase the penetration of NSCs into tumor parenchyma and therefore augment their therapeutic utility.

W-1027

TOWARDS THE SYSTEMATIC COMPARISON OF THE PROLIFERATIVE AND DIFFERENTIATION CAPACITY OF NEURAL STEM CELLS AND GLIOBLASTOMA STEM CELLS

Lionel Meyer[1], Aurore Fernandez[1], Christel Herold-Mende[2], Pierre Kehrli[3], Dominique Bagnard[1]
[1]MN3T, INSERM, Strasbourg, France, [2]Department of neurosurgery, University of Heidelberg, Heidelberg, Germany, [3]Department of neurosurgery, Hospital of Strasbourg Hautepierre, Strasbourg, France

One of the most striking discoveries of the past ten years in the field of cancer is the existence of cancer cell populations exhibiting stem cell like properties. These cells exhibit strong capacities of self-renewal, largely contributing to the progression of cancer. This has been particularly well established in glioblastoma, the most severe type of brain tumor. The molecular mechanisms controlling glioblastoma stem cells proliferation, migration and/or differentiation remains elusive. To address this question we developed a systematic approach in order to better understand these mechanisms in human GSC. Human biopsies are immediately processed to generate gliomapsheres using protocols similar to the one used for the production of neural stem cells and neurospheres. Spheres are subjected to immunocytochemistry characterization, sphere formation assay and differentiation assay. GSC behaviors are compared to the one of NSC.
Here, we will present such a comparison between NSC and NCH644 GSM previously generated from a patient biopsy. We found that both type of stem cells grow equally well giving rise to a rate of spheres production (RSP) of 4-6% over a period of 4 days (6.4% versus 6.2% p=0,9837). In this assay we used NSC between passages 5-10 and GSC between passages 20-32 in order to get stable RSP. Interestingly, we showed that both types of spheres were producing similar extracellular matrix molecules as demonstrated by equivalent staining for Laminin isoforms and

tenascin. When differentiating NSC and GSM on Poly-L-Ornithine, we found that spheres were producing similar proportion of MAP2 (neuronal marker) and GFAP (astrocyte marker) positive cells (20.2% versus 18.2%, p=0,5420 and 68.6% versus 66.7% p=0,5136 respectively). However, GSC showed increased percentage of O4 (oligodendrocyte marker) compare to NSC (19% versus 46% $p < 0.0001$). Interestingly, a various proportion of cells we co-stained for MAP2 and GFAP or GFAP and O4.
To address the migration and differentiation capacities of both types of spheres in culture conditions better reflecting the in vivo situation we are currently developing a slice overlay assay in which spheres are grown on the top of brain slices freshly prepared from postnatal mouse brain. While too preliminary for quantitative analysis our results suggest no regional preference for adhesion and migration. Further investigation will allow us to monitor differentiation when exposed to such in vivo-like conditions.

MESENCHYMAL TRANSITION OF GLIOBLASTOMA STEM CELLS BY VEGF BLOCKADE

Kosuke Funato, Petrina Georgala, Rong Wang, Leif A. Droms, Viviane S. Tabar
Department of Neurosurgery, Memorial Sloan-Kettering Cancer Center, New York, NY, United States

Glioblastoma is the most malignant form of brain tumor and accounts for approximately 54% of all primary brain tumors. Despite huge clinical efforts, the median survival of glioblastoma patients has remained 1 year over the past decade. Since dysregulated angiogenesis and vascular malformation are one of the hallmark features of glioblastoma, the emerging antiangiogenic therapy including anti-VEGF antibody Bevacizumab (Avastin) has been considered as a promising therapy for glioblastoma. However, recent studies indicate that tumors become refractory to antiangiogenic therapy and the effect on overall survival is still controversial. Therefore, there is an urgent need to reveal the molecular and cellular mechanism of insensitivity to Bevacizumab.
It has been shown that glioblastoma stem cells (GSCs) are resistant to chemotherapy and radiotherapy, and contribute to recurrence. To investigate the role of GSCs in response to antiangiogenic therapy, we isolated CD133-positive GSCs from fresh tumor samples. Bevacizumab treatment of CD133-positive GSCs increased migration (14.9-fold, $p<0.01$) and expression of mesenchymal marker genes, such as PDGFRB and SMA (1.8 and 3.8-fold, respectively). Increased expression of mesenchymal genes was also observed in Bevacizumab-treated patients' samples and organotypic slices ("explants"), further indicating the mesenchymal transition by Bevacizumab treatment. We next isolated mesenchymal GSCs by the expression of PDGFRB. PDGFRB-positive GSCs had higher migratory and invasive capacity in comparison with PDGFRB-negative GSCs (1.4-fold, $p<0.004$). In addition, when injected into explants, PDGFRB-positive cells migrated to blood vessels, which is consistent with perivascular tumor invasion observed in Bevacizumab-treated patients. Finally, we found that PDGFRB-positive but not -negative GSCs differentiated to SMA-positive mural cells by the combination of Bevacizumab and TGF-β treatment (PDGFRB-positive, 33.6 ± 4.1 % *vs* negative, 3.8 ± 2.3 %, $p<0.003$), implying PDGFRB-positive GSCs share features with pericyte progenitor cells.
Taken together, our data indicates that Bevacizumab treatment induces the transition of CD133-positive GSCs to the mesenchymal lineage and PDGFRB can be used as a good marker for this transition.

W-1031

OCT4A ISOFORM ENHANCES AGRESSIVENESS OF MEDULLOBLASTOMA CELLS

Patrícia B G Silva, Carolina O. Rodini, Márcia Cristina T. Santos, Daniel Sanzio G. Cruz, Karina G. Oliveira, Oswaldo K. Okamoto
Biosciences Institute, São Paulo University, São Paulo, Brazil

Expression of OCT4 has been recently correlated with poor prognosis in different types of cancer including medulloblastoma, the most common and challenging type of embryonal tumor in childhood. However, direct evidence of OCT4 contribution to tumor aggressiveness is lacking. In this regard, defining the specific contribution of distinct OCT4 isoforms derived from alternative splicing is of particular importance. In this study, the effects of OCT4A overexpression on cell properties conferring a more aggressive tumor phenotype were determined in medulloblastoma.

Stable overexpression of OCT4A was performed by retroviral transduction of DAOY cells, followed by analyses of cell proliferation and tumorigenesis in vitro. Tumor cell proliferation was verified by population doubling level (PDL) assays, amount of viable cells based on MTT metabolism after 24, 48 and 72 hours, and cell cycle analysis by flow cytometry based on propidium iodide incorporation. In vitro tumorigenesis was accessed by colony formation in soft-agar after 15 days. Western blotting revealed that native DAOY cells express low levels of OCT4A protein. After retroviral transductions, cells displaying different levels of OCT4A overexpression were obtained. Cells with 2 increment were named OCT4A Low (lo) and cells with 4 increment were called OCT4A High (hi). Cells overexpressing OCT4A displayed shorter population doubling time than control cells (DAOY: 29,81±0.75h; Lo: 25.05±0.36h*, hi: 25.00± 0.38h*, *p<0.0001) evaluated after 50 generations in vitro. A similar increase in proliferation was also indicated by the MTT assay in all times tested (p<0.0001) and by cell cycle analysis, in which a higher proportion of OCT4A lo and hi cells were found to be in S and G2 phases, compared with the control cells (DAOY: 52.15±0.49%; lo: 60.76±0.43%*; hi: 58.76±1.11%*, *p<0.0001). Cells overexpressing OCT4A also generated higher amount of colonies when cultivated in soft agar, indicating enhanced anchorage-independent cell proliferation. Noteworthy, colonies of OCT4A overexpressing cells were larger than those of control cells (average diameter: DAOY: 71µm; lo: 241 µm; hi: 816 µm). These findings indicate that expression of OCT4A, an isoform with well characterized function in pluripotency and stem cell self-renewal, contribute to tumor aggressiveness and may be further explored as a potential indicator of poor prognosis in medulloblastoma.

W-1032

BMI1 REGULATES GLI ACETYLATION THROUGH CULLIN3 IN MEDULLOBLASTOMA STEM CELLS

Randy Van Ommeren[1], Chitra Venugopal[1], Branavan Manoranjan[1], Nicole McFarlane[1], Robin Hallett[1], John Hassell[1], Sandra Dunn[2], Sheila Singh[1]

[1]Biochemistry, McMaster University, Hamilton, ON, Canada, [2]Department of Pediatrics, University of British Columbia, Vancouver, ON, Canada

Constitutive activation of the sonic hedgehog (Shh) pathway in neural progenitor cells of the external granular layer (EGL) in the cerebellum is a recently described driver of brain tumour initiating cells (BTICs) in medulloblastoma (MB). We have shown that Shh pathway activation leads to increased production of Bmi1, a polycomb repressor which maintains 'stemness' in BTICs. Our current work demonstrates that up-regulation of Bmi1 by the Shh pathway leads to transcriptional repression of the E3 ligase, Cullin3 (Cul3). Cul3 has been shown to ubiquitinate histone deacetylase 1 (HDAC1), leading to increased acetylation of the Gli transcription factors which further activates the Shh pathway. Importantly, we utilize chromatin immunoprecipitation (ChIP) to demonstrate direct binding of Bmi1 to the Cul3 promoter exclusively in CD15+ MB stem cell populations.
This project is carried out with minimally cultured cells derived from primary patient tumours obtained through REB-approved protocols as well as with MB cell lines, Daoy and Med8a. Bmi1 and Cul3 expression is modulated using overexpression (OE) and inducible Tet-On® lentiviral-mediated shRNA knockdown (KD) vectors. mRNA and protein levels of Bmi1 and Cul3 following OE and KD are assessed by RT-PCR and western blotting (WB) respectively. Functional effects of OE and KD are analyzed by self-renewal and proliferation assays. Acetylation status of the Gli transcription factors is assessed by immunoprecipitation using anti-Gli antibodies and subsequent probing for acetyl-lysine on a WB. Bmi1 occupancy at the Cul3 promoter is elucidated through ChIP using Bmi1 antibody on CD15-sorted cells followed by PCR amplification of Cul3 promoter regions. Finally, the functional significance of the pathway in MB BTICs will be assessed using our in vivo BTIC xenograft model. Mice will undergo intracranial injection of MB cells carrying inducible Tet-On® shCul3 vector.
To date, ChIP analysis has demonstrated that Bmi1 is enriched at the Cul3 promoter in CD15+ stem/ progenitor cells though not in CD15- non-stem cells. Overexpression of Bmi1 has been shown by RT-PCR to cause reduced levels of Cul3 transcript, and an inverse result was observed for Bmi1 knockdown. Further, WB analysis shows that overexpression of Bmi1 leads to a reduction of Cul3 protein and a corresponding increase of HDAC1 in Med8a tumor spheres. Future functional elucidation of the pathway in vivo should demonstrate that Bmi1 KD produces less aggressive tumours by reducing Shh pathway activation in injected MB BTICs.

We suggest the existence of a positive feedback loop whereby Bmi1 can repress transcription of the Cul3 E3 ligase. This in turn leads to reduced ubiquitination of HDAC1 and increased Gli deacetylation which further activates Bmi1 transcription and drives the positive feedback system. We have previously demonstrated MB BTICs to be Shh-receptive cells that respond to ligand produced by bulk tumour. Our new findings suggest a novel mechanism whereby aggressive activation of the Shh pathway seen in neural progenitor cells of the EGL and MB BTICs may result in reduced expression of Cul3 as a result of increased repression by Bmi1. These findings pertain to both normal cerebellar development as well as cancer, and describe a novel pathway element responsible for producing a bona fide BTIC in pediatric MB. A more defined understanding of the pathways which promote a BTIC phenotype in the tumour cells of MB patients will provide novel drug targets for future therapies.

W-1033

DEMETHYLATION OF HISTONE 3 LYSINE 27 REGULATES THE SECRETION OF INFLAMMATORY FACTORS RESPONSIBLE FOR THE ROBUST TROPISM OF THERAPEUTIC NEURAL STEM CELLS

Michael E. Silva[1], Patrick Perrigue[1], Daniel Mota[2], Lauren Joseph[2], Joseph Najbauer[1], Karen S. Aboody[1]
[A]Neurosciences, [B]Eugene & Ruth Roberts Summer Academy, [1]City of Hope, Duarte, CA, United States

Neural stem cells (NSCs) have demonstrated their utility as a delivery vehicle for targeted cancer therapy and ischemic injury. However, defining what regulates the robust secretion of chemokines that attract NSC migration toward the tumor or sites of ischemia sites have not been clearly elucidated. Many of these secreted factors have been associated with recruiting a host immune response. JMJD3, a histone 3 lysine 27 demethylase, has been shown to be involved in wound healing and tumorigenesis. Here, we investigate the epigenetic role JMJD3 has in recruiting NSC migration towards human glioma cell lines and senescent-induced fibroblasts. To test our hypothesis of stem cell migration towards glioma or human senescent-induced fibroblasts, we began by using a Boyden chamber-based cell migration assay. Our data indicates that JMJD3 is both necessary and sufficient to activate the robust expression of chemokines that may be responsible for significantly increasing the migration of our therapeutic NSC line (HB1.F3.CD) nearly 17-fold, as well as mesenchymal stem cells (MSCs), towards conditioned media collected from human glioma cell lines as well as senescent human dermal fibroblasts. We further show that the expression of these specific inflammatory factors is both necessary and sufficient through an epigenetic mechanism involving JMDJ3 using ChIP analysis. We also used a human cytokine antibody array, rt-PCR and FACS analysis to identify multiple factors and their corresponding receptors that have previously been shown to be necessary and sufficient in directing NSC migration. In vivo studies are in progress. Collectively, these data will help expand our understanding of the tumor biology involved in stem cell migration and may lead to the increased efficacy of applying NSCs to target and deliver therapeutic agents to tumor foci for cancer therapy as well as other diseases associated with chronic inflammation.

W-1034

NANOG EXPRESSION IN HUMAN ESOPHAGEAL SQUAMOUS CELL CARCINOMA

Marta Cañamero[1], Manuel Rodriguez-Justo[3], Manuel Serrano[2], Daniela Piazzolla[2]
[A]Histopathology, [B]Tumor Suppression Group, [1]CNIO, Madrid, Spain, [2]Pathology, Department of Researh Pathology, University College Hospital, London, United Kingdom

Esophageal carcinoma is the eighth most common cancer and the sixth leading cause of death from cancer worldwide and one of the most common malignant diseases in China. It can be subdivided in two major histological types: Adenocarcinoma (EAC) and squamous cell carcinoma (ESCC). Unfortunately the majority of ESCC patients have locally advanced or metastatic disease at the time of diagnosis and the overall 5-year survival is poor. Screening and early diagnosis of esophageal cancer remains a challenge in spite of introduction of new endoscopic techniques. Although the identification of biomarkers in diagnosis and tumour progression and, the identification of

new therapeutic targets is an area of active research; no biomarkers have been translated to routine clinical practice yet.
NANOG is a homeobox transcription factor that has been identified as a key player in the establishment of embryonic stem cells (ES cells) identity and functions in concert with other transcription factors such as SOX2.
There are several studies reporting NANOG expression in a variety of human tumors, such as gonadal germ cell tumors, central nervous system germinomas, medulloblastoma, glioma and epithelial tumors.
Here we investigate NANOG expression in formaline-fixed paraffin-embedded sections of 29 patients (18 males and 11 females) of ESSC by immunohistochemistry and we discovered that NANOG is expressed in 100% of the cases with a perinuclear or nuclear pattern. In addition, we compared NANOG expression with its stem partner SOX2, that has been recently described to be amplified in human ESCC, finding a correlation between their expressions. These data suggest that NANOG could be a possible new biomarker for use in ESCC diagnosis. Its potential as a predictive and behavioral marker would require further studies.
We are currently carrying out a parallel analysis of NANOG expression in a variety of ESSC cell lines.

W-1035

STEMNESS PROTEIN LEVEL: A SURROGATE MARKER FOR TAMOXIFEN RESISTANCE BREAST CANCER

Issam Hussain, Khalid Arif, Carol Rea, Mohamed El-Sheemy
School of Life Science, Univ of Lincoln, Lincoln, United Kingdom

Introduction: It is well documented that using antihormonal therapy with tamoxifen significantly improves the survival rate of women with oestrogen-receptor positive (ER+) breast tumours. However, the development of resistance to tamoxifen as a primary therapy and disease reoccurrence limits its clinical benefit. This therapeutic failure has revived interest in the breast cancer stem cell (BCSC), since stem cells were reported to be resistant to antihormonal therapy. Stemness" genes expression increases in undifferentiated cells. However, the role of their expression in breast cancer is still poorly defined. The aim of this study was to examine the role of stemness proteins in breast cancer cell lines and anti-hormonal therapy resistance.
Method: MCF-7, MCF-7/tamoxifen resistant (TAMR) and MDA-MB238 cells were cultured, with relevant hormonal therapy to calculate ED50 and incubated in 5% CO2 incubator at 37°C. Quantitative and qualitative immunophenotyping of cells was achieved using fluorescein isothiocyanate (FITC) labelled antibodies reactive with NANOG, SOX2, OCT4 and CD44.
Result: MDA-MB238 cells showed significant expression of NANOG (70%), CD44 (85%) SOX2 (68%) and OCT3-4 (50%) compared with MCF-7(12%, 4%, 15% and 10% respectively). However the MCF-7 TAMR demonstrated lower expression of NANOG (45%), CD44 (60%), SOX2 (60%) and OCT3/4 (55%) compared with MDA-MB238.
Conclusion: Stemness proteins are highly expressed in breast cancer cells resistant to tamoxifen therapy. There is association between the expression of Stemness proteins level and the development and progression of breast cancer resistance to tamoxifen therapy

W-1036

TRANSIENT EXPRESSION OF REPROGRAMMING FACTOR IN VIVO LEADS TO TUMOR DEVELOPMENT

Kotaro Onishi[1], katsunori Semi[1], Akito Tanaka[1], Takuya Yamamoto[1], Masahito Shimizu[2], Hisataka Moriwaki[2], Shinya Yamanaka[1], Knut Woltjen[1], Yasuhiro Yamada[1]
[1]Kyoto Univ CiRA, Kyoto City, Japan, [2]Gastroenterology, Gifu Univ graduate school of medicine, Gifu city, Japan

Induction of 4 transcription factors, Oct3/4, Sox2, Klf4, Myc in differentiated somatic cells has yielded induced pluripotent stem cells (iPSCs). Although generation of iPSCs does not required changes in genomic sequence, iPSC acquired indefinite growth potential: the key characteristic shared with cancer cells. In this study, we generated a reprogrammable mouse in which reprogramming factor expression can be controlled temporally in vivo by the treatment of Doxycycline (Dox).

Induction of reprogramming factors in vivo caused active cell proliferations and a rapid expansion of dysplastic lesions in the epithelial tissues. Prolonged expression of reprogramming factors caused invasive growth of dysplastic cells, leading to cancer development in various organs.
Following longer period of reprogramming factors induction, we observed dysplastic proliferating cells in the kidney, which continued neoplastic growth even after Dox withdrawal. Histological analysis revealed that these Dox-independent kidney tumors resemble Wilms' tumor, a common pediatric kidney cancer. In addition, microarray analysis demonstrated that many upregulated genes in the Dox-independent kidney tumors were similarly upregulated in Wilms' tumor.
Our results suggest that aspects of cellular reprogramming may be involved in the development of pediatric cancers.

DUAL EFFECTS OF HUMAN ADIPOSE TISSUE-DERIVED MESENCHYMAL STEM CELLS ON NF-κB PATHWAY IN TUMOR CELL GROWTH OF A549 AND HT-29.

Jung Joo RHYU, Euna KWON, Byeong Cheol KANG
Dep't of Experimental Animal Research, Seoul National University Hospital, Seoul, Korea, Republic of

Human adipose tissue-derived mesenchymal stem cells (hATMSCs) have a great potential as therapies for various diseases and regenerative medicine. Recently, emerging evidence suggests that human stem cells have both promoting and inhibitory effects on tumor growth. However, little is known about factors that make these contradicting results, and the therapeutic use of hATMSCs should be cautious under malignant conditions. The purpose of this study is to determine in which tumor environment hATMSCs have tumor supporting effects or suppressing effects and to understand the underlying mechanism.
We investigated the effect of hATMSCs on growth of 6 different types of tumor cell lines *in vivo*. A-375, A-431, A549, NCI-N87, HT-29 and Capan-1 cell lines were implanted into athymic nude mice. And the each tumor xenograft mice were treated with intratumoral injection of hATMSCs (1×10^5 cells/mouse) once a week for 8 weeks or with PBS injection for control groups instead. Tumor volumes and weights were measured. The results showed that hATMSCs have an inhibitory effect on tumor growth of A549 and Capan-1, but a promoting effect on HT-29. We focused on A549 and HT-29 tumor and performed further protein analysis. The expression level of tumor-related proteins such as NF-κB/p65, Akt, JAK3, STAT3 and β-Catenin was analyzed by western blotting. The results showed there is an obvious correlation between the tumor growth and the expression level of NF-κB/p65. We also confirmed the similar effect of hATMSCs *in vitro*. When A549 or HT-29 tumor cells were co-cultured directly or indirectly with hATMSCs respectively, the proliferation rate of A549 was decreased but of HT-29 was enhanced.
In this study, we demonstrated the dual effects of hATMSCs, which is inhibiting effect on A549 and promoting effect on HT-29, and the correlation between the tumor growth and the expression level of NF-κB. Despite the controversies concerning the relationships between the MSCs and the tumors, the application of stem cells in cancer therapy or regenerative medicine has broad prospective. Therefore, we consider that it is required further research to understand the interactions between stem cells and various types of tumors and those understandings will provide a new clue for stem cell therapy.

EVIDENCE THAT BREAST CANCER STEM AND PROGENITOR CELLS MODIFY TUMOR GLUCOSE METABOLISM IN RESPONSE TO A HYPOXIC MICROENVIRONMENT

Nicole Gordon, Robynn Schillace, Rodney Pommier, Steven O'Neill, Patrick Muller, Arpana Naik, Robert O'Rourke, Juliana Hansen, Jennifer Alabran, Cory Donovan, SuEllen Pommier
Oregon Health & Science University, Portland, OR, United States

Background: Increases in hypoxia response gene expression and aberrant glucose metabolism are observed in breast cancers. This may endow tumors with the plasticity needed to sustain growth in avascular tissues. The ob-

jective of this study was to determine if adaptive changes are mediated through breast cancer stem/progenitor cells (BCSC) and whether this is determined by BCSC oncogene mutations.
Methods: From 15 invasive ductal carcinomas and 11 normal breast reduction specimens, cells variably expressing breast stem/progenitor cell surface markers CD44, CD49f, CD24 (lin-CD31 and CD45) were collected by cell sorting. RNA/cDNA and wgDNA were collected from whole tumor tissues, benign breast tissues and sorted cells. Genomic mutations were examined at 430 sites of 30 oncogenes (Sequenome MassARRAY). Expression of 36 hypoxia and glucose metabolism-related genes (HYPOX-GluMet) was measured by qRT-PCR (Life Technologies microfluidic cards). In addition, a subset of ex vivo benign and malignant breast surgical specimens were grown overnight in hypoxic (1%) or normoxic (21%) conditions prior to cell sorting. Absolute delta Cts in gene expression were calculated and significance was determined by Student's t-test and ANOVA ($p<0.05$).
Results: Compared to benign breast tissue, tumor specimens showed significant increased HIF1a gene expression. BCSC compared to benign stem cells (SC) showed significant changes in HYPOX-GluMet. Specifically, BCSC lin-CD49f+CD24+ and lin-CD49-CD24+ showed decreased SLC2A1 (GLUT1),and lin-CD49f+CD24- showed decreased SLC2A3 (GLUT3), HK2, SLC16A3, G6PD, SOD2 and BNIP3. Benign SC, and breast tissues had few significant inter-group differences in HYPOX-GluMet. In contrast, 3 of 4 BCSC showed significant inter-group variability and decreased HYPOX-GluMet compared to tumors. Lin-CD49f-CD24- BCSC had higher HYPOX-GluMet gene expression than all other BCSC and were similar to tumors. After 24 hours of normoxic or hypoxic exposure, lin-CD49f-CD24+ and lin-CD49f+CD24+ cells decreased in number by 85% and 62% respectively in benign tissues and 82% and 52% in tumors. Lin-CD49f+CD24- and lin-CD49f-CD24- cells increased by 44% and 5.7% respectively in benign tissues and 45% and 2.6% in tumors. HYPOX-GluMet gene expression was influenced by normoxic and hypoxic conditions in SC and BCSC. Hypoxia decreased HYPOX-GluMet in benign SC, while BCSC showed population-specific CD44 expression increased under hypoxia in both SC and BCSC. Four of 15 tumors had PIK3CA mutations, 3 had SMO, and 2 had PIK3CA and SMO mutations (4 previously reported). HYPOX-GluMet did not correlate with the presence of any specific oncologic mutation.
Conclusions: Changes in HYPOX-GluMet occur following malignant conversion of benign SC to BCSC. These changes are not dependent on PIK3CA or SMO mutations. Gene expression profiles indicate that BCSC lin-CD49f+CD24- cells become significantly metabolically less active in tumors. Lin-CD49f-CD24- cells appear to be more committed-progenitor cells, are highly metabolically active, very proliferative and most reflect the HYPOX-GluMet status of the tumors. BCSC are able to adapt to anaerobic and aerobic microenvironments through changes in cell numbers and transcriptional changes. These abilities of BCSC may help ensure that tumors are able to survive under the variable conditions encountered during progressive stages of tumor growth.

THE PLURIPOTENCY FACTOR NANOG IS EXPRESSED IN ADULT TISSUES AND INDUCES HYPERPLASIA WHEN OVER-EXPRESSED

Daniela Piazzolla[1], Adelaida R. Palla[1], Marta Cañamero[2], Gonzalo Gómez-López[3], Orlando Domínguez[4], Sagrario Ortega[5], Beatriz Fernandez-Tresguerres[6], Agustin F. Fernandez[7], Mario F. Fraga[7], Miguel Manzanares[6], Konrad Hochedlinger[8], Manuel Serrano[1]

[A]Tumor Suppression Group, [B]Histopathology Unit, [C]Bioinformatics Unit, [D]Genomics Unit, [E]Transgenic Mice Core Unit, [1]Spanish National Cancer Research Centre (CNIO), Madrid, Spain, [2]Department of Cardiovascular Developmental Biology, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, [3]Cancer Epigenetics Laboratory, Instituto Universitario de Oncología del Principado de Asturias (IUOPA), HUCA, Universidad de Oviedo, Oviedo, Spain, [4]Harvard University and Harvard Medical School/ Massachusetts General Hospital Cancer Center and Center for Regenerative Medicine/ Harvard Stem Cell Institute, Cambridge/ Boston, MA, United States

NANOG is a key transcription factor for the acquisition and maintenance of embryonic stem cells pluripotency. Deletion of *Nanog* in mice causes early embryonic lethality due to the absence of the epiblast and downregulation of *Nanog* in both mouse and human embryonic stem cells (ESCs) predisposes cells toward differentiation. Conversely, over-expression of NANOG renders both mouse and human ESCs cytokine- and feeder layer-independent. NANOG

has been shown to be highly expressed in the inner cell mass, in derived ESCs, in embryonic germ (EG) cells and in embryonal carcinoma (EC) cells. Contrary to the very well-established role of NANOG in regulating embryonic stemness, the possible function of this transcription factor in adult tissues is still unexplored. Interestingly, recent studies have reported the expression of NANOG in some specific human tumors, suggesting that this stemness transcription factor could also play a role in cancer.
In order to investigate the presence of NANOG in adult tissues we performed a systematic analysis of the patterns of NANOG expression by immunohistochemistry and *in situ* hybridization in a variety of mouse tissues and we extended this analysis to tumors of different origins. Our data indicates that NANOG is expressed in specific mouse tissues and tumors. These findings were further supported by the analysis of *Nanog* promoter methylation status.
Based on these results, we explored the functions of NANOG in adult life by characterizing a transgenic mouse model where NANOG expression is ubiquitously inducible. We discovered that over-expression of NANOG induces hyperplasia and dysplasia *in vivo* associated with hyperproliferation and increased DNA damage.
We are currently trying to dissect the molecular mechanism underlying NANOG's ability to induce proliferation.

W-1043

P53 LOSS OF HETEROZYGOSITY OCCURS IN THE BONE MARROW AND GIVES RISE TO TUMOR INITIATING MESENCHYMAL STEM CELLS

Yoav Shetzer, sivan kagan
Weizmann institute of science, rehovot, Israel

Cells heterozygous for p53 mutation undergo loss of the WT p53 allele by a process termed loss of heterozygosity (p53LOH) which leads to cancer development. The aim of this study was to challenge the hypothesis that p53LOH occurring in adult stem cells is an initiating event leading to cancer. Interestingly, p53LOH already occurred in the bone marrow (BM) of heterozygous p53 mutant mice, where it may either involve the loss of WT or mutant p53 allele, with a preference of losing the mutant allele. However, *in-vitro* established mesenchymal stem cells (MSCs) isolated from BM of heterozygous p53 adult mice, underwent exclusively WT p53LOH and were able to generate tumors *in-vivo*. WT p53LOH was facilitated with age. Analysis of the gene expression profile along the LOH process in heterozygous p53 MSCs has indicated Homologous Recombination (HR) DNA repair pathway, which is known to be p53 transcription-independent, was up-regulated. Likewise, the expression of *Smarca1,* a chromatin remodeler, was induced. Importantly, *Smarca1* up-regulation was observed during p53LOH process also in Mouse Embryonic Fibroblasts (MEFs). Our results suggest that p53LOH process, occurring in adult stem cells such as MSCs, would raise their risk to become tumor initiating cells.

APOPTOSIS INDUCED BY PGC-1β IN BREAST CANCER CELLS IS MEDIATED BY MTOR PATHWAY

Libin Wang[1], Yinxue Yang[2], Haibing Ma[2], Heng Fan[2], Yongzhao Zhu[2], Yaqing He[2], Yukui Li[2]
[1]Ningxia Human Stem Cell Res Inst,General Hospital of Ningxia Medical university, Yinchuan, China, [2]Ningxia Human Stem Cell Res Inst, Yinchuan, China

The peroxisome proliferator-activated receptor-gamma (PPAR-gamma) coactivator-1β(PGC-1β) is a well-established regulator of the mitochondrial biogenesis. However, the underlying mechanism of PGC-1β action remains elusive. This study reveals that knockdown of endogenous PGC-1β by shRNA leads to a decrease in the expression of mTOR pathway-related genes in MDA-MB-231 cells. After knockdown of PGC-1β, phosphorylation of AMP-activated protein kinase (AMPK), phosphorylation of Rictor on Thr1135, Raptor and S6 protein is inhibited. However, Akt phosphorylation on Ser473 is upregulated and cell apoptosis occurs. In particular, we demonstrate that the level of PGC-1β and mTOR correlated with overall mitochondrial activity. These results provide new evidence that cell apoptosis is orchestrated by the balance between several signaling pathways, and that PGC-1β take part in these events in breast cancer cells mediated by mTOR signal pathway.

HISTONE3 LYSINE9 DI-METHYLATION AND DNA HYPOMETHYLATION DURING THE PRE-NEOPLASTIC STAGE OF EXPERIMENTAL MOUSE GLIOMA

Monica Nistér[1], Xiaobing He[1], Mohsen Karimi[2], Mingqi Qu[1], Anna Hedrén[1], Tomas J. Ekström[2]
[A]Department of Oncology Pathology, [B]Department of Clinical Neuroscience, [1]Karolinska Institutet, Stockholm, Sweden

Glioblastoma is one of the most malignant human tumors. To find new strategies for therapy, we need more knowledge on the essential molecular changes during the early stages of glioma development. We have previously generated a transgenic mouse with forced expression of platelet-derived growth factor B (PDGFB) in astrocytic cells of the brain and crossed these mice onto a p53null background, thereby mimicking the genotype of human secondary glioblastoma. The hGFAPpPDGFB/Trp53 null (B+p53-/-) mice develop glioblastoma-like brain tumors at a high frequency in adulthood. The present work reveals epigenetic changes in the mouse brain tumors and in neural stem/progenitor cells during the pre-neoplastic stage. DNA hypomethylation and elevated Histone3 Lysine9 di-methylation (H3K9Me2) were detected in the tumors by immuno-histochemical stainings. During the pre-neoplastic stage, global DNA hypomethylation was observed in samples of the adult frontal brain lateral ventricular wall (LVW) using the Luminometric Methylation Assay (LUMA), but could not be observed in whole brain samples. Furthermore, elevated H3K9Me2 levels were observed in neurosphere cultures from the B+p53-/- pre-neoplastic brain but not in wild type (WT) neurospheres using immuno-blot analysis. The H3K9Me2 level was also higher in brain tumor spheres compared to neurospheres derived from the same mouse. We propose that epigenetically disturbed neural stem/progenitor cells might be the early targets of neoplastic transformation in the brain.

OVARIAN CANCER STEM CELLS: PREDICTOR FOR THERAPY IN ADVANCED CHEMO-RESISTANT OVARIAN CANCER.

Soma Mukhopadhyay, Prattusha Sengupta, Sudeshna Gangopadhyay, Ujjal kanti Roy, Ashis Mukhopadhyay
Netaji Subhas Chandra Bose Cancer Research Inst, Kolkata, India

Background: Invasive and mesenchymal property of Ovarian Cancer Stem Cells (OCSCs) with CD44+/CD133+ has made them promising target for targeted treatment. Chemotherapy treatment uses medicine to weaken and destroy cancer cells in body, including cells at original cancer site and any cancer cell that may have spread to another part of body. Chemotherapeutic drugs for advanced chemo-resistant ovarian cancer are yet to be well defined. Combination of drugs is also not fully known. Our objective is to define chemotherapeutic drugs and its action in OCSC which is the major reason for chemo-resistance in case of advanced chemo-resistant ovarian cancer patients.
Methods: A total of twenty eight biopsy proven advanced chemo-resistant ovarian cancer patients in the age group of 22-36 years were selected randomly and tested for CD44/CD133 via flowcytometry. Isolated OCSCs were cultured for ex vivo drug sensitivity towards Platinum, Anthracyclin, Docetaxel, Rapamycin, Sunitinib, Sorafenib and Gefitinib. Correlation was drawn between cell differentiations, percentage of stem cells and drug response. Accordingly chemotherapy was designed for a particular patient.
Results: We detected OCSCs in 89.3% of cases. Among positive samples ex vivo drug sensitivity was seen in 5(20%) to Rapamycin, 1(4%) to Sunitinib, 1(4%) to Sorafenib, 1(4%) to Gefitinib, 4(16%) to Platinum, 1(4%) to Anthracyclin, 1(4%) to Docetaxel and rest showed no sensitivity to any drug.
Conclusions: Thus primary aim to target OCSCs at onset of tumors in ovarian cancer patients to control metastasis and relapse of disease was somewhat obtained. Most interestingly, we found that the chemotherapeutic drugs which were less prescribed for ovarian cancer showed greater sensitivity in comparison to the widely used ones. We like to do Animal model study followed by Phase I, II and III Human Clinical Trial to establish our hypothesis for better management of chemo-resistant ovarian cancer.

Chromatin in Stem Cells

AUTOSOMAL SPREADING OF XIST REVISITED.

Agnese Loda, Joost Gribnau
Reproduction and Development, Erasmus University Medical Centre, Rotterdam, Netherlands

In mammals, dosage compensation of sex chromosomal genes between females (XX) and males (XY) is achieved through X chromosome inactivation (XCI). This epigenetic phenomenon involves non-coding RNAs, antisense transcription and histone modifications to distinguish two genetically identical X chromosomes as active (Xa) and silent (Xi) entities within the same nucleus. At the onset of XCI, the X-linked non-coding Xist gene is transcriptionally upregulated on the future Xi. Xist RNA coats the Xi in cis triggering chromosome wide transcriptional inactivation. Although Xist is the major player of the process the molecular mechanism by which Xist RNA spreads along the entire length of the X chromosome is an intriguing open question. Notably, many X to autosome translocations show either inefficient Xist spreading or incomplete inactivation of the autosomal translocated material, suggesting a sequence specific model for Xist spreading in cis (White et al. 1998, Popova et al. 2006). In this context, LINE repetitive elements, which are enriched on X chromosome relative to autosomes have been implicated to confer X-chromosome specificity (Lyon et al. 1998). Nevertheless, we hypothesize that the lack of autosomal inactivation observed in cells with X:autosome translocations reflects negative selection against those cells in which Xist spreading was efficient enough to transcriptionally inactivate the autosomal fraction of the translocation product thus leading to lethal aneuploidy. To further investigate this hypothesis we generated (41, XX dup12) ES cell lines with a tetracycline-responsive Xist transgene integrated on chromosome X, 12, or other autosomes. The use of polymorphic ES cell lines allows us to evaluate the degree of gene inactivation by performing allele specific expression analysis. Silencing of one of the three chromosome 12's in these (41, XX dup12) ES cell lines will not be lethal similar to silencing of one X chromosome in female cells. This may contrast with ES cell lines harbouring transgene integrations on other autosomes. Therefore, comparison of Xist mediated silencing in these different ES cell lines will indicate whether aneuploidy or the LINE density explains reduced Xist spreading on autosomes.

REACTIVATION OF X CHROMOSOME UPON REPROGRAMMING LEADS TO CHANGES IN THE REPLICATION PATTERN AND 5hMC ACCUMULATION

Alexandra Bogomazova, Alexandra Panova, Evgueny Nekrasov, Sergey Kiselev, **Maria Lagarkova**
Vavilov Institute of General Genetics, Moscow, Russian Federation

Once set, the inactive status of the X chromosome in female somatic cells is preserved throughout subsequent cell divisions. The inactive status of the X chromosome is characterized by many features, including late replication. In contrast to induced pluripotent stem cells (iPSCs) in mice, the X chromosome in human female iPSCs usually remains inactive after reprogramming of somatic cells to the pluripotent state, although recent studies point to the possibility of reactivation of the X chromosome. Here, we demonstrated that, during reprogramming, the inactive X chromosome can switch from asynchronous to synchronous replication, with restoration of the transcription of previously silenced genes. This process is accompanied by accumulation of a new epigenetic mark or intermediate of the DNA demethylation pathway, 5-hydroxymethylcytosine (5hmC), on the activated X chromosome. Our results indicate that the active status of the X chromosome is better confirmed by synchronous replication and the re-appearance of 5hmC, rather than by appearance of histone marks of active chromatin, removal of histone marks of inactive chromatin, or an absence of XIST coating.

W-1053

FMR1 METHYLATION DYNAMICS IN FRAGILE X AFFECTED HUMAN EMBRYONIC STEM CELL LINES

Rachel Eiges[1], Michal Avitzour[1], Hagar Mor-Shaked[1], Shira Yanovsky-Dagan[1], Gheona Altarescu[2], Talia Eldar-Geva[3], Ephrat Levy-Lahad[2], Paul Renbaum[2], Silvina Epsztejn-Litman[1]

[A]Stem Cell Research Laboratory, [B]Medical Genetics Institute, [C]IVF Unit, [1]Shaare Zedek Medical Center, Jerusalem, Israel

Fragile X syndrome (FXS) is the most common non-chromosomal form of inherited mental retardation. It is inherited as an X-linked trait and is caused by a CGG trinucleotide repeat expansion (>200 CGGs) in the 5'-untranslated region of the FMR1 gene. The CGG repeat region is embedded within a ~ 1.1kb intragenic CpG island (chrX: 146993092-146994200), spanning from the promoter sequence to intron 1 of FMR1. As a CpG island, this region typically remains free of DNA methylation and is rich in histone modifications associated with transcriptional active chromatin. Yet, expansion of repeat copy number to over 200 CGGs leads to local acquirement of aberrant DNA methylation and repressive histone modifications by an unknown mechanism, resulting in the silencing of FMR1 gene in FXS patients.

Here we report on altogether 9 different HESC lines bearing pathologic expansions larger than 200 copies at the FMR1 gene. This collection of undifferentiated FXS cells, which is the largest to the best of our knowledge, comprises 5 male and 4 female cell lines. Taking advantage of this unique set of cells, we show that aberrant CpG methylation is already present at the 5'-end of FMR1 in the majority of FXS HESC lines (7/9), ranging from 20% to nearly 65%, and is steady over time in culture. Methylation levels are consistently higher downstream *versus* upstream to the CGG repeats, and are correlated with decrease in FMR1 mRNA levels and abnormal acquirement of histone modifications associated with inactive chromatin. Furthermore, by characterizing methylation levels following *in vitro* (embryoid body; EB) and *in vivo* (teratoma) differentiation we show that methylation, when set, can be enhanced by differentiation. This cannot be accounted for by the loss of CTCF binding next to the CGGs, as formerly suggested, since no enrichment for CTCF is detected within this region in wild type and affected HESC lines by chromatin immunoprecipitation experiments. Taken together, the findings of this study demonstrate that (1) aberrant methylation is frequently present near the CGGs in the undifferentiated state (2) differentiation enhances, rather than triggers abnormal CpG methylation at the FMR1 locus; and (3) CTCF does not appear to be involved in protecting the FMR1 region from heterochromatin induction during early embryo development.

Our FXS HESCs provide an exceptional opportunity to follow the dynamics of CpG methylation before complete FMR1 gene silencing is achieved. Furthermore, on a more general level, these HESCs also comprise a powerful model system by which one may investigate how CpG islands lose protection from DNA methylation.

CHD7 REGULATES NEUROGENIC CELL FATE DECISIONS IN MURINE HIPPOCAMPAL ADULT NEURAL STEM CELLS

Kieran M. Jones[1], Pete Scambler[2], M. Albert Basson[1]

[1]Craniofacial Development and Stem Cell Biology, King's College London, London, United Kingdom, [2]Institute of Child Health, University College London, London, United Kingdom

The adult mammalian brain possesses the remarkable capacity to generate new neurons and glia throughout life. This process depends on the presence of neural stem cells (NSCs), which reside in two distinct regions of the forebrain: the subventricular zone of the walls of the lateral ventricles, and the subgranular zone of the dentate gyrus of the hippocampus (SGZ). Hippocampal neurogenesis has been shown to play an important role in certain types of learning, memory formation, and pattern separation. Chromatin remodelling can engage or maintain particular genetic programs and has been shown to play a role in the differentiation and self-renewal of embryonic and postnatal neural precursor cells, mainly affecting the self-renewal of precursor cells. Therefore, an understanding of the role of chromatin remodelling in adult NSCs and their progeny could provide insights into the regulation stem cell maintenance and daughter cell differentiation.

Recently, the chromatin remodelling factor Chromodomain-helicase-DNA-binding protein 7 (CHD7) has been shown to interact with SOX2, a NSC marker, and can also bind to regulatory regions in the vicinity of genes involved in NSC lineage progression. Here, we show that CHD7 is expressed in MASH1+ neuronally-restricted transit-ampli-

fying cells in the SGZ niche . *In vitro* assays using *Nestin-Cre; Chd7$^{flox/flox}$* NSC cultures demonstrate normal growth and normal astrocytic differentiation of Chd7-depleted NSCs, but mutant cells have an impaired capacity to form MASH1+ cells. Using a conditional *GLAST-CreER^{T2}; Chd7$^{flox/flox}$* mouse line to specifically delete *Chd7* in the adult NSC lineage and astrocytes, we show that a short-term deletion of *Chd7* results in a decrease in the number of MASH1+ transit amplifying cells and DCX+ neuroblasts, with a reciprocal increase in the number of astrocytes in the dentate gyrus. We demonstrate that deletion of *Chd7* from the adult NSC lineage also leads to a loss of NSC quiescence in the SGZ, possibly due to loss of quiescent ques from transit-amplifying cells and altered Notch signalling. Using BrdU-labelling studies we find that after a long-term deletion of *Chd7* from the adult NSC lineage fewer DCX+ progenitors and NeuN+ differentiated neurons are formed and a greater number of GFAP+ astrocytes are generated compared to controls. These findings suggest that the loss of NSC quiescence results in the depletion of neurogenic potential over time.
We conclude that CHD7 is required for the generation and / or maintenance of neuronally-restricted transit amplifying cells in the adult dentate gyrus, and loss of *Chd7* results in astrocytic differentiation instead of neuronal differentiation with a concurrent loss of NSC quiescence. These experiments identify a role for chromatin remodelling in regulating daughter cell differentiation and stem cell maintenance in a neurogenic niche in the adult mammalian brain.

HMGN1 MODULATES NUCLEOSOME OCCUPANCY AND DNASEI HYPERSENSITIVITY AT THE CPG ISLAND PROMOTERS OF EMBRYONIC STEM CELLS

Tao Deng[1], Iris Zhu[1], Shaofei Zhang[1], Fenfei Leng[2], Srujana Cherukuri[1], Loren Hansen[1], Leonardo Mariño-Ramírez[1], Eran Meshorer[3], David Landsman[1], Michael Bustin[1]
[1]NIH, Bethesda, MD, United States, [2]Florida International University, Miami, FL, United States, [3]The Hebrew University of Jerusalem, Jerusalem, Israel

Chromatin structure plays a key role in gene expression and embryonic differentiation; however the factors that determine the organization of regulatory sites in chromatin are not fully known. Here we show that HMGN1, a nucleosome binding protein ubiquitously expressed in vertebrate cells, preferentially binds to CpG islands-containing promoters, and affects the organization of nucleosomes, DNaseI hypersensitivity, and transcriptional profile of mouse embryonic stem cells and neural progenitors. Loss of HMGN1 alters the organization of an unstable nucleosome at the transcription start sites, reduces the number of DNaseI hypersensitive sites genome wide, and decreases the number of Nestin-positive neural progenitors in the SVZ region of mouse brain. Our study provides insights into the mechanisms whereby an architectural nucleosome binding protein affects chromatin structure during embryonic stem cell differentiation.

W-1056

ROLE OF NUCLEOSOME POSITIONING IN HUMAN EMBRYONIC STEM CELLS

Puya G. Yazdi, Brian Pedersen, Jared Taylor, Ping H. Wang
Medicine, University of California at Irvine, Irvine, CA, United States

Human embryonic stem cells (hESCs) hold great potential to radically alter human medicine. This potential is a result of their pluripotent potential which is a direct consequence of their epigenomic state. The nucleosome, the fundamental repeating unit of chromatin, plays a pivotal role in influencing epigenetics by two major mechanisms: first by their positioning in the genome, thereby allowing access to DNA from certain transcription factors while covering binding motifs of others; second, nucleosomes can undergo extensive post-translational modifications on their histone tails, which has been demonstrated to effect transcription. In order to elucidate the role nucleosome positioning plays in hESC biology we have generated roughly 60x fold coverage of the human genome by illumina paired-end sequencing of mnase-digested H1 embryonic stem cell mononucleosomes. Our ultra

deep sequencing has begun to demonstrate the role nucleosome positioning plays in the epigenetics of stem cells. Our results indicate that not only are certain underlying DNA sequences enriched within a nucleosome, but that methylated cytosines are also greatly enriched within nucleosomes. Additionally, we have also studied the association of '5-hydroxymethylcytosine and nucleosome positioning. Finally, we have integrated chromatin state maps with our high depth nucleosome maps, to demonstrate the relationship of nucleosome positioning within a certain chromatin state. This has allowed us to determine the occupancy changes of nucleosomes within each state, the fuzziness of their binding, and the distance within the genome from one nucleosome to the other.

IDENTIFICATION OF ADULT HUMAN SOMATIC CELLS THAT CAN GENERATE ALL THREE TISSUE LINEAGES

Thea D. Tlsty, Somdutta Roy
Pathology Department and UCSF Helen Diller Comprehensive Cancer Center, University of California San Francisco Pathology, San Francisco, CA, United States

The cellular mechanisms that generate heterogeneity and the emergence of cell-cell interactions that underlies development and the formation of functional tissues of the body are still a major mystery. Stress disrupts the status quo of tissue homeostasis and sets in motion cellular processes that result in dynamic cellular interactions to accomplish wound healing. Recent work from our group has identified multiple consequences of this disruption that range from changes in cell fate to modulation of the environmental niche. Under certain circumstances, restoration of homeostasis and repair is achieved. Under other circumstances, these consequences collude to create a pro-tumorigenic niche.
Surprisingly, the abovementioned stress-induced cellular processes can also activate the ultimate program of heterogeneity, pluripotency. We have identified cells within human adult tissue that can acquire a pluripotent state. These rare cells can be directly isolated from the human body and be shown to create functional derivatives of heart, brain, bone, cartilage, gut and many more tissues. This rare subpopulation is poised to transcribe pluripotency markers, Oct3/4, Sox2 and Nanog at levels similar to those measured in human embryonic stem cells and to acquire a pluripotent state sensitive to environmental programming. In vitro, in vivo and teratoma assays demonstrated that either a directly-sorted (uncultured) or a single cell (clonogenic) cell population from primary human tissue has the ability to differentiate into functional derivatives of each germ layer, ectodermal, endodermal and mesodermal. In contrast to other cells that express Oct3/4, Sox2 and Nanog, these human endogenous Plastic Somatic cells (ePS cells) are mortal, express low telomerase activity, expand for an extensive but finite number of population doublings, and maintain a diploid karyotype before arresting in G1. These cells may provide insights into the origins of tissue (and tumor) heterogeneity and the dynamic cellular interactions that underlie tissue generation.

ANALYSIS OF PROTEIN-PROTEIN INTERACTIONS USING BAC-TRANSGENIC HUMAN PLURIPOTENT STEM CELLS AND THEIR NEURONAL PROGENY

Jonas Doerr[1], Marco Y. Hein[2], Ina Poser[3], Irina Solovei[4], Jerome Mertens[1], Heinrich Leonhardt[5], Anthony A. Hyman[3], Matthias Mann[2], Philipp Koch[1], Oliver Brüstle[1]
[1]Inst of Reconstructive Neurobiology, Bonn, Germany, [2]Max Planck Institute of Biochemistry, Martinsried, Germany, [3]Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, Germany, [4]Biozentrum, Department of Biology II Anthropology & Human Genetics, Munich, Germany, [5]Department of Biology II Anthropology & Human Genetics, Munich, Germany

While contemporary approaches in cell-based disease modeling have been focusing mostly on the effects of defined mutations on the cellular phenotype, the assessment of underlying alterations in the interactomes of disease-relevant proteins has faced several technical challenges. First, experiments were typically conducted using

overexpression paradigms resulting in unphysiologically high protein levels and thus unspecific interactions. Second, such studies have been relying mostly on transformed cell lines, which enable mass production of cells but do not represent a tissue-specific proteomic environment. We aimed at addressing these issues by BAC-based expression of tagged proteins in pluripotent stem cell-derived long-term self-renewing neuroepithelial stem cells (lt-NES cells), a stable and robust cell population, which generates authentic human neurons with high fidelity. Tagged proteins were found to be expressed at endogenous levels, and FISH analyses revealed an average integration rate of one copy per genome. Correct size and compartmentalization of the tagged proteins could be confirmed by high-resolution live cell imaging and Western blot analysis. Employing this approach, we generated multiple cell lines, which harbor tagged proteins exhibiting altered expression in human developmental disorders, cancer and neurodegeneration, including PCNA, AURKA, CDK2AP1, RUVBL2, the Methyl CpG Binding Protein 2 (MECP2) and the Alzheimer's disease-associated proteins Nicastrin (NCSTN) and Valosin-containing protein (VCP). Using a label-free, quantitative affinity purification-mass spectrometry approach, we identified numerous novel interaction partners of these proteins. Direct comparison of the interactomes of proliferating lt-NES cells and their neuronal progeny further revealed changes in the composition of several chromatin remodeling complexes, suggesting that our system suffices to identify developmental switches in such complexes.

STEM CELL BASED MODELS OF MONOGENETIC FORMS OF DIABETES

Dieter Egli[1], Linshan Shang[1], Haiqing Hua[1], Rudolph Leibel[2]
[1]NYSCF, New York Stem Cell Foundation, New York, NY, United States, [2]Pediatrics, Columbia University, New York, NY, United States

All forms of diabetes are caused by an inability of beta cells in the pancreas to provide sufficient insulin in response to elevated blood glucose levels. Stem cell models of diabetes could be useful to study the mechanisms of beta cell failure, and to investigate how beta cell function can be restored. To determine whether stem cell derived beta cells faithfully reflect the phenotype of a diabetic subject, we generated induced pluripotent stem cells from diabetics carrying mutations in genes involved in beta cell function, including glucokinase (GCK) and wolframin (WFS1). We found that beta cells derived from these stem cells reflect key aspects of the phenotype of the diabetic subject: GCK mutant stem cell lines show a reduced ability to secrete insulin in response to glucose, while WFS1 mutant cells are highly sensitive to endoplasmatic reticulum stress. Importantly, these phenotypes can be reverted upon gene sequence correction by homologous recombination. Our disease models provide an entry point into studying the effect of specific genotypes on beta cell function.

W-1064

ACTIVATION OF ADULT PANCREATIC STEM CELLS IN TYPE 1 DIABETES AND THEIR CONTRIBUTION TO β-CELL REGENERATION

Rozita Razavi, Sarah Abdullah, Derek van der Kooy
Univ of Toronto, Toronto, ON, Canada

The contribution of pancreatic stem cells in β-cell regeneration of adult tissue has been shown in pancreatic injury models. However, these studies have suggested the de-differentiation or trans-differentiation of adult pancreatic cells such as ductal and acinar cells as the main source of β-cell neogenesis.
Here we show the presence and contribution of a rare pancreatic (islet) cell population under diabetic conditions that contributes to β-cell regeneration in the adult tissue. We had previously shown that these pancreatic multipotent stem cells (PSCs) exist in the adult tissue and are capable of producing pancreatic and neuronal progenies in-vitro as well as in-vivo. These cells express insulin but lack the expression of β-cell specific glucose transporter, Glut2, or express it at very minimal levels.

We first used Streptozocin (STZ) that enters β-cells through Glut2 and destroys them, to induce diabetes in mice. Using colonal sphere assay, we observed that the STZ-induced diabetic islets have greater numbers of PSCs that also produce larger spheres. Moreover, the STZ-induced diabetic spheres produce more insulin+ progenies when differentiated.
In order to test the effects of β-cell stress on PSC function, we used NOD and NOD.Scid mice that show abnormal β-cell hyperactivity at around weaning time. At this time the autoimmune reaction starts in NOD mice, which eventually leads to β-cell loss and diabetes. In NOD.Scid, due to lack of immune response, only β-cell hyperactivity but no major physiological complications such as diabetes occurs. We observed that in NOD mice the number of PSCs significantly declines around 6 weeks of age. Since insulin is a major target for autoimmune reaction in Type1 diabetes (T1D) in NOD, and because PSCs also express insulin, this observation is expected. However, in the absence of autoreactivity and presence of β-cell stress, in NOD.Scid, similar to STZ model, the number and the size of PSC colonies increase. NOD snd NOD.Scid PSC colonies also produce significantly higher numbers of insulin+ progenies compare to the proper control strain, NOR mice.Interestingly we observed similar findings in human diabetic samples when compared with PSCs obtained from healthy donors' tissue.
To study the involvement of PSCs in in-vivo β-cell regeneration during diabetes, we used a doxycycline (dox) induced- β-cell -specific diphtheria toxin expressing transgenic mouse model. These mice develop diabetes after 7 to 10 days of dox treatment. However, when the dox treatment ends, β-cell regeneration rescues normoglycemia in these animals. Previous studies suggested β-cell self replication as the mechanism of regeneration in this diabetes model. Although in these studies, insulin was used only as a mature β-cell marker, thus the possible contribution of PSCs was ignored.
As was expected, at the onset of diabetes, the number of PSCs is significantly reduced in dox treated mice. However, throughout the recovery, there is a significant increase in the number and size of PSC spheres that declines and reaches the control level after 8 weeks. The number of insulin producing progenies from the PSC colonies also follows the same pattern in these mice.
Collectively, our findings suggest that human and mouse diabetic PSCs are more proliferative and potent in producing insulin+ cells. Moreover, when conditions allow, the adult pancreatic stem cells' contribution to β-cell regeneration can reverse diabetes.

HUMAN PANCREATIC PROGENITOR CELLS IN 3D ORGANOID CULTURE AND GENERATION OF INSULIN-PRODUCING CELLS

Nerys A. Williams[1], Cindy JM Loomans[1], Léon CA van Gurp[1], Femke CAS Ringnalda[1], Toshiro Sato[2], Marten A. Engelse[3], Ton J. Rabelink[3], Hans Clevers[1], Eelco JP de Koning[1]
[1]Hubrecht Institute, Utrecht, Netherlands, [2]Department of Gastroenterology, School of Medicine, Keio University, Tokyo, Japan, [3]Department of Nephrology/Clinical Islet Transplantation, Leiden University Medical centre, Leiden, Netherlands

An attractive regenerative medicine approach towards β-cell replacement therapy is the derivation of insulin-producing cells from adult stem/progenitor cells. In the embryo, pancreatic multipotent progenitor cells (MPCs) give rise to all cell types of the pancreas. Identification of putative human pancreatic MPCs and insight into their plasticity can provide important clues for generation of insulin-producing cells.
Human islet-depleted pancreatic tissue was cultured using a novel 3-dimensional (3D) Matrigel-based system. With this system, pancreatic tissue could be expanded into complex 3D structures, henceforth referred to as 'organoids. Endocrine differentiation capacity of these organoids was analysed by transplantation of the organoids under the kidney capsule of immunodeficient mice. Putative progenitors were isolated by flowcytometry using the Aldefluor kit to detect cells with high Aldh protein expression. Differential gene expression profiles of sorted $Aldh^{hi}$ vs. $Aldh^{lo}$ fractions were obtained by microarray, and results were validated by qPCR and IHC. The colony-forming capacity of $Aldh^{hi}$ and $Aldh^{lo}$ cells was determined by plating 2-200 cells/µl Matrigel.

Organoids expanded for 7 days' culture resemble the embryonic ductal tree, with budding structures including tip-trunk sections. Expansion can be achieved over several passages for up to 3 months. Immunohistochemical analysis shows that expanded organoids are predominantly ductal in origin (92% $Ck19^+$), with expression of pancreatic progenitors markers ($Pdx1^+$, $Sox9^+$) and pronounced proliferative activity ($Ki67^+$) in the tip section of budding structures. Organoids transplanted under the kidney capsule of immunodeficient mice, give rise to insulin-positive cells (<1% of transplanted tissue), demonstrating that organoids have endocrine differentiation capacity. Aldefluor staining of expanded organoids *in vitro* reveal a high expression of Aldh exclusively in tip cells of budding structures. After cell sorting, clonogenic assays show 3% of $Aldh^{hi}$ single cells initiate organoid growth, whereas $Aldh^{lo}$ cells do not. Expression of genes previously described as multipotent markers of tip cells of the branching ductal tree during embryonic development (*Pdx1*, *Ptf1a*, *Myc* and *Cpa1)* is 3- to 7-fold higher in $Aldh^{hi}$ cells compared to $Aldh^{lo}$ cells. At the protein level, Cpa1 is co-expressed with Aldh in tips, and these cells are negative for the mature acinar marker amylase.
Our data indicate that 3D culture of human pancreatic tissue derived from the ductal compartment gives rise to pancreatic organoids that harbour progenitor cells at the branching tips resembling pancreatic development. Taken together with the generation of insulin-positive cells from organoids after transplantation *in vivo*, these data illustrate the potential of human postnatal pancreatic cells derived from the ductal compartment as an alternative cell source for β-cell therapy.

CHEMICALLY TRANSDIFFERENTIATED FIBROBLAST FROM DIABETIC PATIENTS GENERATES PANCREATIC ENDODERM LIKE-CELLS IN VITRO AND GLUCOSE-RESPONSIVE INSULIN-SECRETING CELLS IN VIVO

Federico Pereyra-Bonnet, Maria Laura Gimeno, Nelson Argumedo, Johana Cardozo, Sung Ho Hyon, Marcelo Ielpi, Emiliana Herrero, Carla Gimenez, Marta Balzaretti, Patricia Fainstein-Day, Monica Loresi, Leon Litwak, Pablo Argibay
ICBME, Hospital Italiano, Buenos Aires, Argentina

Transdifferentiation of skin fibroblasts is a promising alternative for autologous replacement of pancreatic cells in patients with type 1 diabetes (T1D). However, the existing transdifferentiation technique uses genetic modifications which encompass clinical risks. We report here the transdifferentiation of skin fibroblasts from T1D patients into pancreatic like cells using only drug-based induction. For this goal, skin fibroblasts were extracted from two patients with T1D and one healthy volunteer and were cultured *in vitro* following a sequential multistep differentiation protocol including IGF1, Nicotinamide, Exe-4, ITS, B27 and glucose during 30 d. The chemically transdifferentiated cells showed islet-like cluster morphology and expressed the key genes and pancreatic transcription factor (e.g. INS, GCG, STT, PAX4, NGN3 and PDX1) detected by RT-PCR. We observed that our chemical protocol provoked modifications on a transcriptome-wide scale by microarrays. Between 655 and 1060 genes were either up-regulated or down-regulated by more than 2-fold in transdifferentiated cells compared to untreated cells. Some of the up-regulated genes were directly related to the pancreatic lineage or related with chromatin remodeling as INSIG1, NKX2.2, LOC651872, TGM2, TGF-b ligands, Nestin, BMPs and Smads, but none of them matched the typical markers hESC demonstrating the transdifferentiation nature of our protocol. Some of the down-regulated genes were related to the fibroblasts, such as CD34, Elastin, Filamin B, COL12A1 and COL8A1. The qPCR analysis showed that in transdifferentiated cells GCG and INS were up-regulated, and ASPN and MEOX2, two genes related to fibroblasts, were both down-regulated by more than 10-fold. PDX1 promoters were hypomethylated whereas OCT-4 and NANOG were isomethylated, in comparison with parental fibroblasts. The immunocytochemical and Inmunolite ® analysis detected Glucagon (in 30% of the cells) and C-peptide in *in vitro* transdifferentiated cells. Yet transdifferentiated *in vitro* cells showed pancreatic gene expression and proteins, these cells did not respond to glucose stimuli, resembling an inmature pancreatic endoderm stage. In *in vivo* trials, NUDE mice were transplanted intrapancreatically with $3\text{-}9x10^5$ transdifferentiated cells (n=6) or PBS (Sham; n=4) and non-transdifferentiated fibroblasts as a negative control (n=4). Fifteen days later the mice were treated with streptozotocin (STZ). Mice with implanted transdifferentiated cells (50%; n=3) showed detectable levels of human insulin (pM<200) and no teratoma formation. Sham and 30 d fibroblast control mice did not show detectable serum levels of human insulin. Moreover, one

of the 4 mice challenged showed a human insulin-secreting glucose-responding behavior (4-fold increase), demonstrating functionality of transdifferentiated cells *in vivo*. Additionally, transdifferentiated cells prevented the mice from high glycemia peaks ($p<0.006$) and weight loss above 10-15%, even though diabetes was not reversed during the 15 day monitoring phase post STZ. These findings demonstrated that using only drug-based induction could transdifferentiated fibroblasts from T1D patients, resulting in pancreatic endoderm like-cells *in vitro* and responsive insulin-secreting cells *in vivo*. This novel technique opens new possibilities for "transgenic-free" regenerative medicine in patients with T1D and demonstrated the potential plasticity in the adult non-stem cells.

A STEM CELL MODEL OF DIABETES DUE TO GLUCOKINASE DEFICIENCY

Haiqing Hua[1], Linshan Shang[2], Hector Martinez[2], Matthew Freeby[1], Thomas Ludwig[1], Liyong Deng[1], Ellen Greenberg[1], Charles LeDuc[1], Wendy Chung[1], Robin Goland[1], Rudolph Leibel[1], Dieter Egli[2]
[1]Columbia University, New York, NY, United States, [2]New York Stem Cell Foundation, New York, NY, United States

Loss of beta cell mass and/or beta cell function, leading to deficiency of insulin relative to metabolic need and causes diabetes. To determine whether stem cell-derived beta cells recapitulate the cell-autonomous molecular/cellular phenotypes of endogenous beta cells of patients with a monogenic form of diabetes, we generated induced pluripotent stem cells (iPSCs) from subjects with maturity onset diabetes of the young (MODY). We have differentiated these stem cells *in vitro* into beta-like cells and have also transplanted pancreatic endoderm into immunocompromised mice to promote the differentiation of these cells into functioning beta cells. Using homologous recombination-mediated gene targeting, we were able to correct the mutated gene sequence. We found that these stem cell-derived beta-like cells accurately reflected beta cell phenotypes of MODY subjects, and that these phenotypes were fully reverted upon gene correction. These cells can be used for mechanistic analyses of these and genetic causes of diabetes.

THE GCTM-5 EPITOPE ASSOCIATED WITH THE THE MUCIN-LIKE GLYCOPROTEIN FCGBP MARKS DUCTAL PROGENITOR CELLS IN LIVER, ESOPHAGUS, AND PANCREAS

Alison Farley[1], David Braxton[2], Kouichi Hasegawa[3], Martin F. Pera[1]
[1]Univ of Melbourne, Melbourne, Australia, [2]Emory University, Atlanta, GA, United States, [3]Kyoto University, Kyoto, Japan

Previously we described a monoclonal antibody GCTM-5 that is reactive with a large glycoprotein complex present on the surface of stem and progenitor cells of endodermal origin. There are a limited number of specific cell surface markers for endodermal progenitor cells. Therefore, in this study we sought to characterize further the expression of the GCTM-5 epitope in normal and diseased tissues. The antigen was strongly expressed on hepatoblasts at early stages (7.5 weeks) of human liver development. Later in gestation, the marker was found on periportal hepatocytes and the ductal plate, a structure that contains a bipotential stem cell population that persists in the Canal of Hering in the adult liver. Cells with the features of stem or progenitor cells in the ducts of the normal adult liver, pancreas, and esophagus all stained strongly, as did precancerous cells in the esophagus (intestinal metaplasia) and pancreas (pancreatic intraepithelial neoplasia). Submucosal gland cells of the esophagus, now regarded as a putative precursor of intestinal neoplasia, were also reactive with GCTM-5. Five out of seven cultured cell lines from pancreatic ductal carcinoma tested showed cell surface staining by indirect immunofluorescence and flow cytometry. The antigen secreted or shed into the culture medium by the antigen positive pancreatic carcinoma cell lines was not well resolved in immunoblots of conventional SDS-polyacrylamide gels, but migrated as a single diffuse band with an apparent MR of ~850 kDa in native Coomassie polyacrylamide gel electrophoresis. The large mucin-like glycoprotein FCGBP represented a major component of this multiprotein complex. Immunohistochemistry on tissue microarrays showed strong cell surface staining on 100/116 cases of pancreatic ductal carcinoma, but the antigen

was absent from most cases of colorectal, ovarian, breast or lung cancer. The GCTM-5 antigen identifies progenitor cells in ducts within tissues of endodermal origin that are implicated in repair and neoplasia.

PDX1 CONTROLS A GENE REGULATORY NETWORK REQUIRED FOR ESTABLISHING HUMAN PANCREATIC ENDODERM IDENTITY

Ruiyu Xie[1], Allen Wang[1], Tommy C. Harper[1], Logan J. Everett[2], Hee-Woong Lim[2], Olivia G. Kelly[3], Allan J. Robins[3], Kyoung-Jae Won[2], Klaus H. Kaestner[2], Maike Sander[1]

[1]Department of Pediatrics and Cellular & Molecular Medicine, University of California San Diego, La Jolla, CA, United States, [2]Department of Genetics and Institute for Diabetes, Obesity and Metabolism, University of Pennsylvania, Philadelphia, PA, United States, [3]ViaCyte Inc., San Diego, CA, United States

A major goal in efforts to establish a curative diabetes therapy is to generate transplantable replacement pancreatic beta-cells from patient-derived pluripotent cells. The first step in producing cells of the pancreatic endocrine lineage from pluripotent stem cells is to establish pancreatic identity in vitro. Using a pancreatic differentiation protocol of human embryonic stem cells (hESCs) that recapitulates embryonic progression through multiple lineage intermediates, we generated genome-wide mRNA expression profiles by RNA-seq and demonstrated that the establishment of the pancreatic endocrine lineage involves stepwise activation of pancreas-specific genes. Here, we show that induction of the earliest pancreatic factor PDX1 at the primitive foregut stage is necessary to initiate and promote pancreatic lineage progression. Knockdown of PDX1 with a specific shRNA triggers distinct changes in gene expression including loss of pancreatic progenitor genes SOX9, NKX6.1, and PTF1A. Thus, much like in mouse development, PDX1 is required for the developmental progression of human pancreatic endoderm. In addition, genome-wide multistage studies by ChIP-seq reveal that induction of pancreatic endoderm is accompanied by progressive removal of H3K27me3 from a cluster of pancreatic endoderm genes, such as SOX9, NKX6.1 and PTF1A, as cells transition from the primitive foregut stage to a more differentiated state. Since induction of the pancreatic program coincides with the loss of H3K27me3, we suggest that PDX1 may be involved in the activation of a pancreatic-specific gene network by assisting in the establishment of an “active” chromatin landscape. This may be facilitated by the recruitment of histone demethylases, which could remove the repressive H3K27me3 chromatin mark. We have, thus, established a system that enables us to gain a more mechanistic understanding of pancreatic lineage specification by identifying interactions between transcription factors and histone modifiers during this dynamic process.

IN VITRO REPROGRAMMING OF ADULT PANCREATIC DUCT CELLS TO INSULIN-PRODUCING BETA CELLS BY DEFINED TRANSCRIPTION FACTORS

Takatsugu Yamada[1], Claudia Cavelti-Weder[1], Lili Guo[1], Arun Sharma[1], Weida Li[2], Qiao Zhou[2], Susan Bonner-Weir[1], Gordon C. Weir[1]

[1]Islet Cell and Regenerative Biology, Joslin Diabetes Center, Boston, MA, United States, [2]Stem Cell and Regenerative Biology, Harvard Stem Cell Institute, Cambridge, MA, United States

Background: The reprogramming success of iPS cells opened the possibility of converting one mature cell type directly into another by forced expression of transgenes. We have previously shown that injection of adenoviral vectors encoding three pancreatic transcription factors, *Pdx1*, *Ngn3* and *Mafa*, into mouse pancreases results in reprogramming of exocrine cells to insulin-producing cells in sufficient numbers to reverse diabetes. **Aim**: We hypothesized that the cultured pancreatic duct cells (PDCs) could be reprogrammed to become insulin-producing beta cells by forced expression of transgenes. **Methods**: PDCs were isolated from adult MIP-GFP transgenic mice, allowing insulin-expressing cells to be detected by GFP fluorescence. The cultured PDCs were transfected by an adenoviral vector carrying a polycistronic construct Ngn3/Pdx1/Mafa/mCherry (Ad-M3C) or mCherry sequence alone (Ad-C) as

a control. In addition, we examined the effect of GLP-1 receptor agonist, exendin-4 on the reprogramming. **Results**: 8-12% of cultured PDCs were reprogrammed to GFP-positive insulin-expressing cells by transduction of Ad-M3C. Administration of Ad-M3C resulted in increased expression of beta cell markers insulin 1 and insulin 2, and exendin-4 enhanced this expression. Expression of other beta cell markers, neuroD and GLP1R, were also significantly upregulated in the reprogrammed cells. The total amount of insulin release into the media and insulin content in the cells were significantly higher in the cells transduced by Ad-M3C than those by Ad-C. Furthermore, exendin-4 had a marked effect not only on the insulin content but also on the insulin secretion of the reprogrammed cells. Ad-M3C-transduced cells did not secrete insulin in response to increased glucose, suggesting incomplete differentiation to beta cells. **Summary**: Cultured PDCs have been reprogrammed into insulin-producing beta cells by adenoviral delivery of three pancreatic transcription factors (Ngn3/Pdx1/MafA). Exendin-4 could enhance this process. This is the first report describing *in vitro* direct conversion of cultured mature PDCs to generate new insulin-producing cells. This study provides novel insights into the reprogramming of cultured PDCs to insulin-producing beta cells as the most promissing approach for beta cell replacement therapy for diabetes.

DEVELOPMENT OF AN EFFICIENT DIFFERENTIATION METHOD FROM IPSCS/ESCS INTO PANCREATIC EXOCRINE LINEAGES TOWARDS NOVEL PANCREATIC DISEASE MODELS

Michinori Funato[1], Taro Toyoda[1], Yasushi Kondo[1], Yoshiya Hosokawa[1], Tomomi Sudo[1], Keisuke Okita[1], Isao Asaka[1], Motonari Uesugi[2], Zen-Ichiro Kato[3], Akira Ohta[1], Shinya Yamanaka[1], Naomi Kondo[3], Kenji Osafune[1]
[1]Center for iPS Cell Research and Application (CiRA), Kyoto University, kyoto, Japan, [2]Institute for Chemical Research, Kyoto University, Uji, Japan, [3]Department of Pediatrics, Graduate School of Medicine, Gifu University, Gifu, Japan

Human induced pluripotent stem cells (iPSCs), which take over individual patient characteristics, have the potential to be used in the study of complex diseases that result from not only genetic but also a mixture of genetic and environmental factors. Therefore, the work on establishment of directed differentiation methods from iPSCs/embryonic stem cells (ESCs) into a variety of somatic cell types has been vigorously performed around the world. The generation of pancreatic exocrine cells will be required for studying the disease mechanisms of acute pancreatitis, chronic pancreatitis, and congenital pancreatic exocrine dysfunction including Shwachman-Diamond syndrome (SDS) and Pearson syndrome. Although some previous reports have described that pancreatic exocrine cells can be differentiated from mouse and human iPSCs/ESCs, the efficient differentiation methods for the cell types have not been established so far. Herein, we report the development of an efficient differentiation protocol from iPSCs/ESCs into pancreatic exocrine lineages. We have slightly modified a previously published protocol from human iPSCs/ESCs into pancreatic progenitor cells, and obtained the highly efficient induction (approximately 70% to 80%) of PDX1 (+) pancreatic progenitor cells that could give rise to all pancreatic cell types including exocrine cells. Then, high-throughput screening (HTS) of chemical compounds was performed, and we identified a small molecule that can efficiently induce pancreatic progenitor cells into AMYLASE (+) cells at approximately 30% to 40% of induction efficiency. The small molecule proved to act synergistically with indolactam V (a protein kinase C activator), resulting in the generation of approximately 50% to 60% of total cells expressing AMYLASE. These AMYLASE (+) cells induced with the chemical compound expressed other pancreatic exocrine lineage markers, such as CPA1, LIPASE and ELASTASE, and showed the synthesis and release into the culture medium of functional alpha-AMYLASE protein. In contrast, the differentiation into pancreatic ductal cells or endocrine lineages was not significantly induced by the small molecule treatment. Furthermore, we found that the chemical compound also induced pancreatic exocrine lineages from mouse ESCs-derived pancreatic progenitor cells. These results suggest that our differentiation protocol with a novel chemical compound can efficiently produce pancreatic exocrine cells from mouse and human iPSCs/ESCs, and that the exocrine cells may be used for elucidating the mechanisms of pancreatic development as well as for creating novel in vitro disease models.

W-1074

AN ARTIFICIAL EXTRACELLULAR MATRIX PROTEIN SUPPORTS DIFFERENTIATION OF COLONY-FORMING CELLS FROM POSTNATAL MOUSE PANCREAS INTO BETA-LIKE CELLS IN VITRO

Nadiah Ghazalli[1], Alborz Mahdavi[2], Tao Feng[1], Liang Jin[1], Jasper Hsu[1], David A. Tirrell[2], Arthur D. Riggs[1], Hsun Teresa Ku[1]

[1]*Diabetes & Metabolic Diseases Research, Beckman Research Institute of City of Hope, Duarte, CA, United States,* [2]*Department of Bioengineering, California Institute of Technology, Pasadena, CA, United States*

Pancreatic stem and progenitor cells are potential sources for producing unlimited insulin-expressing beta cells to treat type 1 diabetes. In our previous studies, we established two pancreatic colony assays; one contains Matrigel, and the other an artificial extracellular matrix (ECM) protein containing a laminin-IKVAV sequence (termed laminin hydrogel). These colony assays allow quantitative and functional assessment of colony-forming cells isolated from adult murine pancreas, which we found to contain cells capable of self-renewal and differentiation into beta-like cells in vitro. The purpose of the current study is to determine whether postnatal pancreas also contains colony-forming cells, and whether the laminin-IKVAV sequence in the laminin hydrogel is necessary for their biological functions. Postnatal pancreas (1 week old) was dissociated into single cell suspension by collagenase B and DNase I and plated into methylcellulose semisolid media containing either 1) Matrigel, 2) laminin hydrogel, or 3) a protein hydrogel with a control scrambled sequence. We found that one week after plating, approximately 2.5, 1.3 or 1.5% of plated cells gave rise to colonies in the presence of laminin hydrogel, scrambled hydrogel or Matrigel, respectively. Cells supported by both types of hydrogel proteins expressed higher levels of endocrine and acinar markers, whereas those supported by Matrigel had higher ductal gene expression. Laminin hydrogel further enhanced expression of insulin genes compared to the scramble control. Cultures supported by laminin hydrogel, scramble control or Matrigel contained approximately 12, 6 or 1% C-peptide+ (a surrogate marker for insulin) cells, respectively, as determined by flow cytometry analysis. Individually handpicked colonies (n=6 from each group) developed from cultures containing laminin hydrogel but not other ECM proteins expressed higher level of Insulin2 gene by microfluidic qRT-PCR analysis. These colonies were C-Peptide positive as determined by whole-mount immunostaining. When challenged with high concentrations of D-glucose, laminin hydrogel-supported colonies were able to secrete C-Peptide into culture media. In summary, these results demonstrate that laminin hydrogel and Matrigel have opposing effects on cell lineage differentiation, and laminin-IKVAV sequence is necessary to support the development of insulin-secreting beta-like cells in vitro. These results identify postnatal pancreas as a potential source of beta-cell progenitor cells that could further be explored for regenerative medicine.

W-1075

CLONAL HETEROGENEITY WITHIN THE EXOCRINE PANCREAS

Damian Wollny, Xiaokang Lun, Ana Martin-Villalba
German Cancer Research Center (DKFZ), Heidelberg, Germany

The pancreas consists of two functional units: the hormone producing endocrine system and the digestive enzyme producing exocrine pancreas. Much effort has been made to investigate if the endocrine system is organized hierarchically. However the progress made in the past decade concluded that the endocrine system is not organized in a hierarchical way and that all beta cells contribute equally to growth and maintenance. If this is also the case for the exocrine pancreas remains elusive. Here we use multicolor lineage tracing to study the clonal contribution of cells within the acinar cell population, the major compartment of the exocrine pancreas. While examining potential progenitor populations we find substantial differences in the proliferation dynamics of single clones among acinar cells. As a complementary in vitro approach to assess clonal heterogeneity, we examine the organoid-forming capacity of these cells. In this assay, we identified a unique subpopulation of acinar cells with the ability to give rise to organoids. Thus, although the acinar population, similarly to the beta cells among the endocrine cells, is often considered as a homogeneous population we find clonally heterogeneous contribution to growth and maintenance of pancreas homeostasis. Furthermore these data challenge the perception of the pancreas as a quiescent organ.

HUMAN PARTHENOGENETIC STEM CELL-DERIVED HEPATOCYTES CORRECT SERUM BILIRUBIN IN GUNN RATS

Larissa Agapova, Alina Ostrowska, Trudy Christiansen-Weber, Tiffany Chu, Ruslan Semechkin
ISCO, Carlsbad, CA, United States

Human liver cell transplantation trials are hampered by the shortage of donor tissue therefore different type of stem cells are being investigated for their potential use in regenerative therapy. Hepatocyte-like cells (HLC) derived from human parthenogenetic stem cells (hpSC) might constitute an easily available source to obtain the large numbers of transplantable cells to treat liver-based inborn errors of metabolism. Here we demonstrate that after the optimized endodermal differentiation in vitro hpSC reaggregate and grow into HLC that are developmentally immature hepatocytes, similar in expression profile to fetal liver cells. Differentiated HLC were characterized by immunostaining, quantitative RT-PCR, biochemical function (LC/MS, ELISA, bioluminescent assays) and in vivo analyses. Hepatocyte phenotype of the obtained cells, was evidenced by demonstrating the enzymatic activity of phase I drug metabolizing enzymes, glycogen storing and the presence of liver-specific proteins, such as albumin, alpha-fetoprotein, alpha 1-antitrypsin and coagulation factors. To evaluate engraftment potential and functional repopulation in vivo, we have treated juvenile Gunn rats (a well established model of Crigler-Najjar disease) by a single intrasplenic injection with 10x106 of HLC, pre-labeled with CFSE. A histological post-surgery examination revealed normal appearance of engrafted cells which continued to have hepatic features. Most importantly, we demonstrated a significant decrease and long-term stabilization of bilirubin levels in the serum of tested animals in comparison with sham-treated controls. In immunosuppressed animals receiving therapeutic doses of HLC, serum indirect bilirubin declined significantly throughout the 19th week observation period. Multiple engrafted cells were observed in the periportal regions of the liver lobules. Many fluorescent cells were also clustered in small groups predominantly around the central veins. Moreover, at four months following treatment no adverse safety signals were detected. The overall liver structure of all tested rats appeared undamaged and no inflammation, tumorigenicity, or apparent rejection signs were observed. In summary, we demonstrated substantial grafting of inoculated hepatocyte-like cells in the recipient Gunn rats within 4 months which was associated with significant and stable reductions of serum bilirubin levels. The data strongly indicate the potential of parthenote-derived hepatocytes as an easily available source to obtain a large number of transplantable cells for regenerative treatments of metabolic liver diseases including Crigler-Najjar syndrome.

PROLIFERATION IS INDEPENDENT OF MATURATION DURING THE DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS TOWARDS HEPATOCYTES

Changjun Zeng, Benjamin Tschudy-Seney, Xiaocui Ma, Tia Hackett, Wei Gao, Ahmad Hasan, **Yuyou Duan**
Internal Medicine, University of California Davis Medical Center, Sacramento, CA, United States

Adult hepatocytes lack the capacity to proliferate in vitro; this hinders their use including hepatocyte-dependent drug discovery and development. Human embryonic stem cells (hESC) are a potential source to generate viable, functioning hepatocytes for clinical application and pharmaceutical use. In this study, we attempted to determine how hESC-derived hepatocytes (hDH) proliferate during differentiation and maturation. hESC lines, H9 and ESI017, were differentiated towards hepatocytes under our established differentiation protocol. hESC was induced to definitive endoderm (DE), then DE were further differentiated towards hepatocytes for 15 days under differentiation medium, and for an additional 21 days with maturation medium. The differentiated cells were counted every other day from day 2 after the initiation of differentiation. In addition, cDNA was generated after RNA was extracted from the counted cells, and supernatant was collected at all time points. Cell counting showed that the cell proliferation peak appeared at day 8 after starting differentiation for both H9 and ESI017 lines, and this proliferation peak was not concentration-dependent. The total cell numbers showed a slight decrease every other day after the medium

was changed for maturation. qPCR results showed that the highest expression of alpha fetoprotein (AFP, immature marker) was between days 12-14, then its expression continued to decrease to the end of the time course. The expression of albumin (ALB, more mature marker) increased continuously to the highest peak at day 30. ELISA results showed that AFP in the medium was highest at day 14 then continued to go down until day 30, and ALB in the medium was detected from day 12 and continued to go up until day 30. These results indicated that the cells were differentiated at day 14, and were more matureat day 30 under our differentiation conditions. We changed our differentiation conditions by employing differentiation medium for the entire time-course or by changing maturation medium from day 8 instead of day 15. Although qPCR results showed that gene expression patterns were changed, the cells did not show proliferation after day 8 of the changed conditions. Expression of Ki67 and PCNA decreased after the differentiation started from DE, with the relative expression levels of Ki67 and PCNA being only 20% as high at day 8 when compared to day 2. This suggested that the proliferation is independent of the differentiation and maturation of hESC towards hepatocytes. Importantly, even though the cells do not proliferate after day 8, this never affected their function at later time points. During the non-proliferation period (days 9 to 30), hDH produced 100 ug ALB in the medium as determined by ELISA, showed a functioning biotransformation system as determined by the cellular uptake and excretion of Indocyanine Green, developed full metabolic function as determined by the metabolic profiling of the drug bufurarol, and could engraft and proliferate in livers after transplantation into immunodeficient mice. The relationship between telomere length change and cell proliferation is under investigation. Thus, our results help enhance our understanding of stem cell derivatives and their use, and also play an important role in developing optimal cryopreservation timing for hESC-derived hepatocytes.

HEPATIC DIFFERENTIATION OF SIMIAN IPSCS: A TOOL FOR CELL THERAPY APPLICATIONS

Clara Steichen[1], Soumeya Abed[2], Sébastien Corbineau[1], Stany Chrétien[2], Anne Weber[1], Philippe Leboulch[2], Leïla Maouche-Chrétien[2], Anne Dubart-Kupperschmitt[1]

[1]Inserm U972, Villejuif, France, [2]Inserm U962/CEA/iMETI, Fontenay aux Roses, France

Pluripotent stem cell based therapy carries great potential in the treatment of liver disease. Indeed, stem cell-derived hepatocyte transplantation represents an alternative to orthotopic liver transplantation, which is limited by the lack of donor and the difficulty to expand hepatocytes in vitro. However, before any clinical application, the safety, efficacy and feasibility of this therapeutic approach has to be established in large animal models, including nonhuman primates, who are physiologically and phylogenetically very close to human. The aim of this work is to demonstrate that autologous simian iPSCs differentiated into hepatocytes are capable of integrating into the liver parenchyma of non-human primates with a sufficient degree of chimerism and functionality. However, despite the fact that many protocols already exist describing the differentiation of human pluripotent stem cells into hepatocyte-like cells, they cannot be directly transferred to monkey ESCs or iPSCs and little is known about the hepatocyte differentiation potential of these cells. A few protocols are already described, but the fonctionallity of simian-hepatocytes like cells in vitro is poorly studied, and their engraftment has not been evaluated yet.
We first generated iPSC lines from primary fibroblasts and bone marrow mesenchymal stem cells of Macaca fascicularis (cynomolgus). We used RT-PCR, flow cytometry and immunofluorescence assays to confirm the expression of the pluripotent endogenous genes OCT3/4, NANOG, SOX2, KLF4, Myc and SSEA4. Intramuscular injection of cy-iPSCs into immunocompromized mice induced the development of teratomas containing tissues of the three germ layers, validating the pluripotency of the cy-iPSCs. The next step was to differentiate these cy-iPSCs into hepatic progenitor cells and hepatocytes and to characterize them in vitro for their phenotype markers and hepatic functions. We have set up chemically defined conditions devoid of serum, to efficiently differentiate cy-iPSCs into endodermal cells showing the expression of specific combination of markers such as SOX17, GATA4, HNF3β and CXCR4. These cells have been differentiated into hepatic specified endoderm showing the expression of liver specific markers such as AFP and HNF4α. We are currently defining conditions to further differentiate these cells into hepatic progenitors and more mature hepatocyte-like cells. Specific liver functions such as albumine secretion, glycogene storage and cytochrome P450 induction capacity will be evaluated.

Given the strong expertise of our surgeon team who already defined protocols to perform efficient hepatocyte engraftment into nonhuman primates, this work should offer a proof-of-concept of autologous stem cell derived hepatocyte transplantation into nonhuman primates and an accurate model to evaluate the therapeutic efficacy and safety of this approach in human patients.

W-1084

SOX9 POSITIVE CELLS OF THE BILE DUCTS- A PROMISING TARGET FOR MAKING BETA CELLS FOR CELL THERAPY OF TYPE1 DIABETES PATIENTS

Anannya Banga, Ying Yang, Lucas Greder, James Dutton, Jonathan MW Slack
Genetics Cell Biology and Development, University of Minnesota, Minneapolis, MN, United States

We have investigated the reprogramming towards a beta cell phenotype of various developmentally related cell types, using the gene combination Pdx1 + Ngn3 + MafA separated by 2A peptides in an adenoviral construct (Ad-PNM). We found that hepatocytes are refractory and cannot be permanently reprogramed towards a beta cell state. But we have shown for the first time that Ad-PNM can uniquely target a progenitor population in the liver and reprogram them into insulin secreting ducts, expressing various markers of beta cells. We have identified this progenitor population as SOX9-positive population of cells residing in the biliary tract, those of which can be reprogramed to insulin secreting ductal structures and can rescue diabetes in mice long term. SOX9 positive progenitor cells are known to serve as a common progenitor compartment for the intestine, pancreas and liver, thus being more developmentally related is believed to possess a more open chromatin at the beta cell genes and can be considered as a promising target for making the desired cells for cell therapy of Type1 Diabetes. Henceforth we have discovered the potential of developmentally related SOX9 positive cells of the bile ducts towards attaining a beta cell fate which opened up new interests to make future beta cells from this progenitor population, thereby overcoming the constraints of using ES or iPS cells. Isolation of the SOX9 positive cells from the bile ducts in the liver using SOX9CreERT2 mice showed that they are a distinct population of epithelial cells, expressing ECAD and SOX9 but not EpCAM, a marker for liver stem cells. These epithelial cells can be isolated in culture from the digested liver as green GFP labeled balls and can be infected with the beta cell transcription factors in vitro to attain a beta cell fate. These cells upon reprograming invitro are found to express an array of beta cell markers along with insulin secretion in response to glucose. Ductal progenitor cells in adult pancreatic ducts and its ability to make beta like cells has been described long time back but its presence in the liver will make it relatively easy to isolate those cells by a small liver biopsy. We henceforth believe that SOX9 positive cells of the bile ducts as novel alternative cell type for making beta cells and holds enormous possibilities for generating autologous human beta cells for transplantation therapy.

VEGFR2/KDR IDENTIFIES A HUMAN MESENCHYMAL HEPATIC PROGENITOR AND INSTRUCTS EARLY LIVER DEVELOPMENT

Orit Goldman[1], marion Sourisseau[1], Noelle Dziedzic[1], Corneo Barbara[2], Sunita D'Souza[1], Matthew Evans[1], Valerie Gouon-Evans[1]
[1]mount sinai school of medicine, new york, NY, United States, [2]2Neural Stem Cell Institute, Rensselaer, NY, United States

The capacity of embryonic stem cells (ESC) to form hepatocyte-like cells (hepatic cells) in culture provides a unique model system for liver developmental studies and the generation of transplantable cells for cell therapies to overcome the shortage of liver donors. Using human ESC lines, we have established conditions for efficient endoderm development assessed by the co-expression of CXCR4 and cKit. Isolated day5 CXCR4+cKit+ endoderm cells were further cultured in hepatic conditions. In order to examine the emergence of potential endothelial cells in hepatic cultures, previously shown to support hepatic differentiation (Han et al., Stem Cells, 2011), expression for endothelial markers VEGFR2 (KDR) and PECAM-1 (CD31) were monitored. Based on CD31 and KDR expression, three populations emerged sequentially: first the KDR+CD31- (K+C-) pre-hepatic cells negative for AFP protein (~50% at day 12), then the KDR+CD31+ (K+C+) endothelial cells (~5% at day12), and lastly the KDR-CD31- (K-C-) hepatic cells expressing AFP protein (~50% at day12).
Gene expression analyses by qPCR showed that K-C- and K+C- populations expressed equal transcript levels of the ventral endoderm marker GATA4 and the epithelial hepatic marker CK18. However, levels of the endoderm and hepatic markers FOXA2, AFP and Albumin were higher in K-C- cells compared to those in K+C- cells, suggesting that K+C- cells progressed to an intermediate hepatic fate. Interestingly, levels for the mesenchymal markers Vimentin and Snail1 were always higher in K+C- cells compared to those in K-C- cells and inversely correlated with levels of the epithelial marker E-Cadherin, compatible with a more mesenchymal phenotype of K+C- cells.
To determine whether the pre-hepatic K+C- cells represent a progenitor for the hepatic K-C- cells, hepatic potential was examined in a three-dimensional aggregate culture that favors maturation. In aggregates, virtually all K+C- cells expressed AFP protein, defining the K+C- cells as hepatic progenitors for the K-C- hepatic cells. To demonstrate the functionality of the human K+C- progenitors following further hepatic specification and maturation, we exploited the well-established ability of the hepatitis C virus (HCV) to infect specifically hepatocytes. This functional study revealed that K+C- progenitors supported re-

latively weak HCV replication as expected, yet this improved (40-fold) after further hepatic specification and maturation, to levels comparable to the K-C- hepatic cells and even the best-case Huh-7.5 hepatoma cell line.
Co-culture assays between the K-C- and K+C- populations demonstrated that K+C- cells constitute not only a pool of hepatic progenitors, but also a supportive niche in promoting hepatic specification and maturation of the K-C- hepatic cells. Blocking KDR function or an antibody or small molecules dramatically reduced Albumin transcript levels in K-C- hepatic cells. Induction of hepatic maturation (Albumin expression) was mostly mediated in a non-cell autonomous manner through KDR signaling expressed on the K+C- progenitors.
This study reveals that VEGFR2/KDR, previously thought to be restricted to mesodermal derivatives, is actually a marker for a mesenchymal endoderm-derived hepatic progenitor, and is also a functional receptor instructing early human liver development.

W-1086

AN IN VIVO LINEAGE TRACING STUDY IDENTIFIES AN UNEXPECTED FLK-1 EXPRESSING HEPATIC PROGENITOR

Songyan Han[1], Noelle Dziezdic[1], Alice Bourdon[1], Thomas Sato[2], Valerie Gouon-Evans[1]
[1]Developmental and Regenerative Biology, Mount Sinai School of Medicine, New York, NY, United States, [2]Developmental and Regenerative Biology, Nara Institute of Science and Technology, Nara, Japan

Complex cell-cell communication between endoderm and the microenvironment is required for proper liver development. FGF and BMP signaling from the cardiac mesoderm and the septum transversum, respectively, instructs hepatic specification of the adjacent ventral endoderm. Endothelial cells form a necklace around the specified hepatic endoderm and promote hepatoblast expansion. Using the mouse embryonic stem cell (ESC) differentiation system, we have recently demonstrated that endothelial cells are not only required for hepatic cell expansion, but are also required earlier for the hepatic specification of endoderm by dual repression of Wnt and Notch signaling [Han et al, Stem Cells, 2011].
In the attempt to track the emergence of endothelial cells in mouse ESC hepatic differentiation cultures, we examined expression for the early endothelial marker Flk-1 (VEGFR2, KDR) as well as the endoderm marker Foxa2. For this purpose, we used a reporter ESC line allowing us to isolate progenitors for endoderm based on brachyury and Foxa2 expression. Upon hepatic specification of isolated endoderm progenitors, two main populations consisting of a Foxa2+Flk-1- hepatic fraction and a Foxa2-Flk-1+ endothelial fraction developed. Surprisingly, a transient Foxa2+Flk1+ population also emerged and displayed bipotential hepatic and endothelial fates following further culture. This in vitro study suggested the existence of an unexpected endoderm-derived hepatic progenitor expressing the mesodermal marker Flk-1. Indeed, Flk-1 expression was thought to be restricted to mesodermal derivatives including endothelial, hematopoietic, cardiac and skeletal muscle precursors.
In order to provide an in vivo evidence for the existence of a Flk-1 expressing hepatic progenitor, mouse embryos from E8.0 (prior to hepatic specification), E9.5 (liver bud stage) and E13.5 (fetal livers) were examined for Flk-1 and the endoderm marker Foxa2 expression by immunohistochemistry. Scattered Flk-1+Foxa2+ cells were detected in endoderm and were strictly found in E8.0 embryos prior to hepatic specification. To demonstrate the hepatic fate of the Flk-1+Foxa2+ endoderm cells, an in vivo lineage tracing mouse model was analyzed in which all Flk-1 expressing cells as well as their progeny were labeled genetically. This mouse model expresses YFP under the ubiquitous Rosa26 locus specifically in Flk-1+ cells and progeny of Flk-1+ cells (Cre-Flk-1 x Rosa26-LoxpSTOPLoxpYFP). By tracking the YFP+ cells in developing fetal livers (E13.5), we determined that out of 36 fetal livers analyzed, all of them were consistently constituted with between 30% to 50% of YFP+ hepatoblasts that were derived from a Flk-1 progenitor. In turn, the YFP+ hepatoblasts gave rise to a subset of YFP+ adult hepatocytes based on albumin and HNF4α expression, as well as YFP+ cholangiocytes based on CK19 and Sox9 expression.
Altogether, this lineage tracing study provides for the first time the in vivo proof for the existence of an unexpected endoderm-derived hepatic progenitor expressing the mesodermal marker Flk-1.

THE IDENTIFIATION OF CANCER STEM CELL MARKER IN HEPATITIS B VIRUS INFECTED PRIMARY HEPATOCYTE CELLS

YEN SHUN CHEN, KUAN WANG
Institute of Biological Chemistry, Taipei, Taiwan

The liver cirrhosis and hepatocellular carcinoma (HCC) disease is ranking as the third leading cause of cancer-related death and the fifth most common solid cancer in the worldwide. Several lines of evidence implicate HCC is correlated with the infection of hepatitis B virus (HBV) that activate and deregulate multiple signaling transduction pathways in hepatocarcinogenesis. The cancer stem cell (CSC) has been demonstrated in tumor progression, tumor resistance to chemo/radiation therapy and tumor relapse in HCC patients. It's important to elucidate the roles of putative target genes/proteins that should be taken into consideration when designing therapeutic strategies for HCC in the HBV infected liver. We investigated the signaling pathway of HNF-4alpha, EpCAM, CD13, $CD44^+$, $CD90^+$, CD133, Wnt/β-catenin, TGF-β, Notch and Hedgehog in the HBV infected live by the techniques of RT-PCR, flow cytometry and confocal microscopy. Here we provide a brief view of molecular signaling in CSCs related marker protein and present insights into new therapeutic strategies for targeting HBV-infected HCC.

REGULATION OF CYTOCHROME P450 3A11 EXPRESSION IN MOUSE HEPATIC PROGENITOR CELLS BY BCL-6

Hiromi Chikada[1], Keiichi Ito[2], Ayaka Yanagida[2], Hiromitsu Nakauchi[2], Akihide Kamiya[1]
[1]*Laboratory of Stem Cell Therapy, Institute of Innovative of Science and Technology, Tokai University, Isehara, Japan,* [2]*Division of Stem Cell Therapy, Center for Stem Cell and Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, Chiyoda-ku, Japan*

[Background]
Adult liver is a central organ for intermediary metabolism, in particular detoxification. Hepatocytes are major parenchymal cell type of the liver and express several metabolic genes. Many human hepatocytes are needed in regenerative medicine for severe liver diseases and analyses of drug metabolism. However, proliferation of mature hepatocytes *in vitro* is difficult in spite of their high regenerative capacity *in vivo*. Differentiation of highly proliferative hepatic progenitor cells to mature hepatocytes after expansion might provide a method to obtain large quantities of functional hepatic cells.
[Objective]
For effective maturation of hepatoblasts, fetal hepatic progenitor cells, into mature hepatocytes *in vitro*, we analyzed transcription factors regulating hepatic functional genes.
[Methods]
To search the candidate genes regulating hepatic differentiation, expression micro array analyses were performed in both adult hepatocytes and embryonic day 13 (E13) hepatoblasts. We considered genes whose expression levels were higher in adult hepatocytes than E13 hepatoblasts as the candidates. These genes were overexpressed using retovirus vectors in the culture system, which induced maturation of hepatoblasts by the addition of oncostatin M and extracellular matrices.
[Results]
We found several transcriptional and nuclear factors were highly expressed in mature hepatocytes but not E13 hepatoblasts. One of these candidate factors was B cell lymphoma (Bcl) 6. Overexpression of Bcl-6 increased expression of cytochrome P450 (CYP) 3A11, the important drug detoxification enzyme, in E13 hepatoblasts culture. In contrast, other detoxification enzymes (CYP2B10, CYP3A16, CYP7A1) and metabolic genes (tyrosine aminotransferase and carbamoylphosphate synthetase) were not up-regulated by overexpression of Bcl-6. Moreover, expression of transcriptional factors important in liver development such as hepatic nuclear factor 4α and 3β also weren't changed by overexpressed Bcl-6. These results suggested that Bcl-6 directly regulated expression of CYP3A11 in hepatic cells. Bcl-6 is a transcription factor consisting of C2H2 type Zinc finger and BTB/POZ domains. Therefore,

we analyzed the Bcl-6 effect on the CYP3A11 promoter using luciferase assay system. As a result, overexpression of Bcl-6 increased CYP3A11 reporter activity through the region from -1725 to -1523.
[Conclusions]
The present study suggests that Bcl-6 is a new regulator of mature hepatic function through the transcriptional regulation of CYP3A11.

CHARACTERIZATION OF LIVER ORGANOID TISSUES COMPOSED OF MURINE HEPATIC PROGENITOR CELLS AND FIBROBLASTS IN DENSE COLLAGEN FIBRILS

Miho TAMAI[1], Hiroshi SAKAI[2], Shinichi Miyagawa[3], Eijiro ADACHI[4], Yoh-ichi TAGAWA[1]
[1]Graduate School of Bioscience and Biotechnology, Department of Biomolecular Engineering, Tokyo Institute of Technology, Yokohama-shi, Japan, [2]Shinshu University School of Medicine, Matsumoto-shi, Japan, [3]Shinshu University School of Medicine, Mastumoto-shi, Japan, [4]Kitasato University, Sagamihara-shi, Japan

Hepatic stem/progenitor cell is one of the promising cell-sources to restore liver mass and its functions. Although hepatic progenitor cells (HPC), such as oval cells, are induced by the administration of some hepatotoxins in experimental animals, such strategy should be inappropriate for the clinical setting. In recent, we succeeded to establish and long-culture HPC clones from non-parenchymal cell fraction of portal branch ligated lobes, PBL-HPCs, in mice. In this study, using the PBL-HPCs liver organoid tissues were tried to be reconstructed in an originally designed bioreactor system. The liver organoid tissue was investigated about transplantation into partially hepatectomized BALB/cA-nu/nu mice.
We succeeded to reconstruct the liver organoid tissues model using a HPCs, embryonic fibroblast, and collagen. The PBL-HPCs acquired the metabolic functions of detoxifying ammonium ions and urea synthesis in the presence of oncostatin M. Several liver-specific gene expressions, such as tryptophan 2,3-Dioxygenase were strongly detected in this system compared to that in the 2D-culture. We have found that angiogenesis was induced by transplantation of liver organoid tissues to the liver organoid tissues and surrounded tissue. A novel approach was demonstrated to generate transplantable liver organoid tissues with condensed collagen fibrils matrix. Based on the sufficient vascular support for the transplanted liver organoid tissues, we expect that it was established a local vascular network at the transplantation site would allow nutrient and gas transport to the grafted liver organoid tissues, and this would reduce graft loss. These results provide future avenues for the potential use of PBL-HPCs in the treatment of liver disease.

W-1092

LONG-TERM CULTURE OF HEPATOBLAST-LIKE CELLS DERIVED FROM HUMAN PLURIPOTENT STEM CELLS

Kazuo Takayama[1], Yasuhito Nagamoto[1], Kenji Kawabata[2], Katsuhisa Tashiro[2], Fuminori Sakurai[1], Masashi Tachibana[1], Hiroyuki Mizuguchi[1]
[1]Laboratory of Biochemistry and Molecular Biology, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Japan, [2]Laboratory of Stem Cell Regulation, National Institute of Biomedical Innovation, Ibaraki, Japan

Hepatoblasts have ability to differentiate into both hepatic and biliary lineages, and to self-replicate. The establishment of self-renewing hepatoblast-like cells (HBC) from human embryonic stem (ES) cells and induced pluripotent stem (iPS) cells would lead to a stable supply of the hepatocyte-like cells for medical application such as drug screening and liver cell transplantation. Although we have previously demonstrated that almost homogeneous HBC population could be generated from human ES/iPS cells (J Hepatol. 2012 Sep;57(3):628-36.), the functional characterization of human ES/iPS cell-derived HBC was still not enough. The human ES/iPS cell-derived HBC was maintained under the appropriate conditions. The expanded human ES/iPS cell-derived HBCs were epithelial cell adhesion molecule+, CD133+, alpha-1-fetoprotein+, albumin+, cytokeratin (CK) 7+, and CK19+. The human ES/iPS cell-derived HBC could differentiate into both the hepatocyte-like cells in presence of hepatocyte growth factor, oncost-

atin M, and dexamethasone, and the cholangiocyte-like cells in presence of epidermal growth factor and insulin-like growth factor 2. The human ES/iPS cell-derived HBC were maintained for more than 3 months. In addition, the human ES/iPS cell-derived HBC have potential to integrate into the liver parenchyma of immunodeficient mice that are damaged by carbon tetrachloride treatment. These results indicated that functional hepatoblasts could be generated from human ES/iPS cells, and they could be maintained in long-term culture. The expandable human ES/iPS cell-derived HBC might be manageable tools for drug screening, experimental platforms to elucidate mechanisms of hepatoblasts, cell source for human ES/iPS cell-based hepatic regenerative therapy.

W-1093

SEMI QUANTITATIVE ASSAY OF CYP3A4 EXPRESSION ALLOWS THE IDENTIFICATION AND SELECTION OF MATURE HUMAN STEM CELL DERIVED HEPATOCYTES

Ryan Rodriguez[1], Kristina Bonham[1], Shinichiro Ogawa[2], Carmina Blanco[1], Danajane Eymer-Vargas[1], Hai-Qing Xian[1], Gordon Keller[2], H. Ralph Snodgrass[1]

[1]VistaGen Therapeutics, Inc., South San Francisco, CA, United States, [2]McEwen Centre for Regenerative Medicine, Toronto, ON, Canada

One of the pitfalls of many pluripotent stem cell differentiation protocols is the extremely poor efficiency of producing mature hepatocytes. The cytochrome P450 3A (CYP3A) subfamily of enzymes is the most predominant in the human liver. In the fetal liver CYP3A7 is the predominant isoform, whereas there is an almost exclusive shift to the CYP3A4 isoform in the adult liver. Furthermore, CYP3A4 is responsible for the metabolism of half of the pharmaceuticals currently available, as well as playing a central role in steroid homeostasis. Most published stem cell differentiation reports demonstrate CPY3A7 expression, but little to no CYP3A4 expression or activity, indicating the lack of maturity of the hepatocyte-like cells being studied. In an effort to address this problem, we generated a human embryonic stem cell (hESC) reporter line containing a humanized version of the beta-lactamase reporter gene (hBLA) targeted to the 3' untranslated region of the CYP3A4 locus. We show the use of this cell line as a semi-quantitative tool for analyzing the expression of CYP3A4 in individual cells and for the selection of mature hepatocytes by fluorescence activated cell sorting. We demonstrate that this assay can be used to monitor the induction of CYP3A4, its expression level over time, and to measure experimental effects on the maturation of hepatocytes. Using an optimized protocol for the differentiation of hepatocyte-like cells, we demonstrate CYP3A4-hBLA expression in 25-40% of the unsorted differentiated cell population. Furthermore these cells show expected adult responses: 1) rifampicin induction, 2) metabolism of known CYP3A4 substrates, 3) albumin production and 4) phase II enzyme activities. Sorted CYP3A4-hBLA cells express levels of CYP3A4 mRNA approaching that in human adult liver on a per cell basis. These data suggest that these cells have many of the functional properties of mature hepatocytes. This system allows us to measure the expression of CYP3A4-hBLA on a per cell basis in response to experimental conditions, and treatments with drugs, and corroborate those data with cytochromes P450 enzyme activities, Phase II enzyme activities, and secretion of hepatic factors, such as albumin and urea. These multiple functional analyses provide a powerful system to evaluate the effects of test compounds on CYP3A4 expression and hepatocyte function, offering a valuable aid for assessing potential drug candidates for toxicity.

COMPARATIVE ANALYSIS OF TRANSPLANTATION EFFICACY OF HUMAN IPS CELL-DERIVED HEPATIC CELLS AT VARIOUS DIFFERENTIATION STAGES IN MICE

Yasuhito Nagamoto[1], Kazuo Takayama[1], Katsuhisa Tashiro[2], Chise Tateno[3], Fuminori Sakurai[1], Masashi Tachibana[1], Kenji Kawabata[2], Kazuo Ikeda[4], Yasuhito Tanaka[5], Hiroyuki Mizuguch[1]

[1]Osaka university, Osaka, Japan, [2]National Institute of Biomedical Innovation, Osaka, Japan, [3]PhoenixBio Co. Ltd., Hiroshima, Japan, [4]Osaka City University, Osaka, Japan, [5]Nagoya City University, Nagoya, Japan

Human liver chimeric mice were typically produced by transplanting cryopreserved human hepatocytes into urokinase-type plasminogen activator-transgenic SCID mice (uPA/SCID mice), which are immunodeficient and undergo liver failure. Human hepatocytes transplanted into this model can repopulate the mice host liver, frequently replacing over 70% of the native liver with human hepatocytes. Recently, researchers have shown that these mice models are applicable for studies of hepatitis virus biology and human drug metabolism. However, human cryopreserved hepatocytes have disadvantages in the limit of their sources, costs and inability of genetic modification. Because hepatocyte-like cells differentiated from human induced pluripotent stem cells (iPS cells) have potential to resolve these problems, they are expected to apply for generation of human liver chimeric mice. We have established the efficient method for hepatic differentiation from human iPS cells by sequential transduction of forkhead box A2 (FOXA2) and hepatocyte nuclear factor 1 homeobox A (HNF1α) using adenovirus vector (J Hepatol. 2012 Sep;57(3):628-36.). The human iPS cell-derived hepatocyte-like cells expressed the similar gene expression levels of hepatocyte-related markers, such as *CAR*, *CYP3A4*, and *CYP2E1*, as compared with those of primary human hepatocytes. To generate human liver chimeric mice by transplanting the human iPS cell-derived hepatic cells, it is necessary to examine which cell type is the most suitable for cell transplantation. In particular, it has not been well-investigated whether human iPS cell-derived definitive endoderm (DE) cells, hepatoblasts, or hepatocyte-like cells will provide better results. To examine whether the transplanted human iPS cell-derived cells could integrate into the liver of uPA/SCID mice, *in vivo* secretion of human albumin (ALB) proteins in mouse blood were measured after the cell transplantation. As a result, human ALB amount in the blood of mouse transplanted with the hepatocyte-like cells could be detected after 1 week from transplantation (approximately 140 ng/ml). Moreover, the concentration of human ALB was increased to approximately 6.7 μg/ml after 4 weeks from transplantation. By contrast, human ALB amount in the blood of mouse transplanted with the DE cells and the hepatoblasts were hardly detected after 4 weeks from transplantation (below 103 ng/ml). The liver of the transplanted mouse was also analyzed by immunostaining and quantitative RT-PCR. Engraftment of the hepatocyte-like cells into the liver of uPA/SCID mice was evidenced by positive staining of human ALB and human CK8/18. In addition, the expression of human genes, such as *ALB*, *α1 anti-trypsin*, *HNF4α*, and *CYP7A1*, was observed only in the liver received the hepatocyte-like cells but not in those received the DE cells and hepatoblasts. In conclusion, the hepatocyte-like cells were much desirable for generation of human liver chimeric mice than the DE cells and hapatoblasts.

Intestinal/Gut Cells

ADULT STEM CELLS IN THE SMALL INTESTINE ARE INTRINSICALLY PROGRAMMED WITH THEIR LOCATION-SPECIFIC DIFFERENTIATION FATE

Sabine Middendorp, Kerstin Schneeberger Schneeberger, Caroline L. Wiegerinck, Michal Mokry, Edward ES Nieuwenhuis
University Medical Center Utrecht, Utrecht, Netherlands

In mammals, the small intestinal epithelium is highly specialized along the cephalocaudal axis with different absorptive and digestive functions in duodenum, jejunum and ileum. Several transcription factors, like GATA4 and CDX2, have been described to regulate location-specific gene expression in the mouse small intestine. However, it is not known whether the intestinal environment, such as the mesenchyme, luminal content or the microbiota is necessary to maintain the location-specific functional properties of epithelial cells.
By using the organoid culturing technique, we cultured pure epithelial cells derived from location-specific crypts of mice and human to exclude the effect of extrinsic factors. We determined expression of location-specific genes, such as Gata4, disaccharidases and bile acid transporters. We show that the *ex vivo* expression signatures remained stable in location-specific mouse organoids that were expanded for up to 12 weeks. Furthermore, human duodenal and ileal organoid cultures that were expanded for 7 weeks and were then induced to differentiate, also maintained their functional identity corresponding with their original location.
These data show that within the small intestine, location-specificity is intrinsically programmed in the adult stem cells and is independent of extracellular signals from either mesenchyme or luminal content.

W-1102

TRANSCRIPTIONAL AND FUNCTIONAL DECLINE OF THE INTESTINAL STEM CELL NICHE DURING THE AGEING PROCESS

Christian M. Nefzger, Katja Horvay, Thierry Jarde, Jaber Firas, Helen E. Abud, Jose M. Polo
Anatomy and Developmental Biology, Monash University, Melbourne, Australia

Organ homeostasis and regeneration are facilitated by multipotent tissue stem cells that give rise to all the mature cell types of a specific organ. During an organism's life, adult stem cell pools are maintained by cell division requiring both the genome and the epigenome to be faithfully copied. However, according to the relatively few studies conducted to date, changes in the epigenome and in consequence gene expression can be detected in a large number of aged organs/tissues. The intestinal epithelium is an ideal model to study aging as it constitutes a high-turnover tissue that is renewed every 4-5 days. Epigenetic changes are likely to accumulate in the intestinal stem cell pool due to its high rate of cell division, and indeed age-related changes in DNA methylation status were shown for whole organ preparations. Coincidentally certain types of cancer (e.g. colorectal cancer) also increase with age, moreover alterations of the epigenome have been suggested to be the underlying causes. Age related changes also impact on functional properties of the intestinal epithelium as evidenced by a reduced capacity to take up essential nutrients like calcium and phosphorus. Combining fluorescent reporter genes and surface marker we have been able to extract intestinal stem cells (ISCs) in large numbers (up to 3*105 cells per animal). When embedded in matrigel intestinal crypts or single ISCs can be cultured in vitro and give rise to so called organoids, intestinal structures with crypt and villus-like epithelial domains that contain all differentiated types of cells. In order to study the effect of aging on the intestinal stem cell niche in detail we have performed immunohistochemical characterization of tissue sections, functional in vitro assays and expression profiling of the stem cell compartment in mice of different age groups (1.5 month, 10 month, 24 month). Our results showed clear changes in intestinal morphology, expression profile and regeneration potential. To further investigate the underlying causes for these functional and transcriptional changes, we are currently studying how different epigenetic modifications in the ISCs are altered during aging.

W-1103

FUNCTIONAL ANALYSIS OF SLC52A3, A TARGET GENE OF BROWN-VIALETTO-VAN LAERE SYNDROME

Atsushi Intoh, Kathryn Koszka, Naoki Suzuki, Nicholas Atwater, Kevin Eggan
Department of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States

Brown-Vialetto-Van Laere (BVVL) syndrome is a neural disease characterized by progressive ponto-bulbar palsy and bilateral sensorineural deafness. BVVL patients also have symptoms of lower motor neuron degeneration, muscle weakness, and amyotrophy. Diaphragmatic weakness is the most distressing feature in BVVL syndrome, leading eventually to respiratory failure. The prognosis for BVVL patients is poor, and most patients die within 10 years of onset. The cause of this disease had long remained unknown. However, mutations in the C20orf54 locus were recently identified in BVVL patients. C20orf54 encodes one member of riboflavin transporter family, and has a mouse homolog; Slc52a3. Riboflavin is a water soluble vitamin, widely known as vitamin B_2. Riboflavin is a precursor of FAD and FMD, which function as cofactors for a number of redox enzymes and play essential roles in the transfer of electrons in biological oxidation-reduction cycles. As humans and the other mammals cannot synthesize riboflavin *in vivo*, they must uptake this vitamin from their diet. However the association with neural differentiation or neurological system is still unknown.
Our question is that how the lack of this gene affects nerve systems in patients. To test for a function link between C20orf54/Slc52a3 and BVVL, we examined Slc52a3-KO mutant mice, embryos, and stem cell lines. As our results, Slc52a3 expresses in intestinal crypt and testis, but not in brain and spinal cord in adult mouse. The main function of Slc52a3 in adult mouse is expected as riboflavin absorption from the diet via intestinal epithelium. During mouse embryo development, Slc52a3 expresses in inner cell mass of blastocysts. In vitro experiments also showed that mouse and human embryonic stem cells have Slc52a3 expression. Moreover, Slc52a3 knock-out mice are em-

bryo lethality. These results suggest that failure of riboflavin uptake in adult intestine and during early development would affect BVVL syndrome.

GENERATION OF STOMACH TISSUE FROM MOUSE EMBRYONIC STEM CELLS.

Takaaki K. Noguchi[1], Naoto Ninomiya[2], Makoto Asashima[3], Akira Kurisaki[1]
[1]Graduate School of Life and Environmental Sciences, The University of Tsukuba, Japan, Tsukuba city, Japan, [2]Department of Life Sciences (Biology), Graduate School of Arts and Sciences, The University of Tokyo, Japan, Meguro-ku, Japan, [3]Research Center for Stem Cell Engineering, National Institute of Advanced Industrial Science and Technology (AIST), Japan, Tsukuba city, Japan

Studies in embryonic development have led to successful efforts in differentiation research of mouse and human embryonic and induced pluripotent stem cells into specific organ cell types in vitro. For example, mouse embryonic stem cells have been differentiated into liver hepatocytes and pancreatic endocrine cells that have therapeutic efficacy in animal models of liver disease and diabetes, respectively. Compare to these organs, however, directed differentiation of stomach lineage from embryonic stem cells has not been reported and remains major challenge for translational studies in stomach disease model. Here, we established efficient differentiation method of mouse embryonic stem cells into stomach tissue. This process involves embryoid-body based intestinal gut-like structure differentiation method induced by sonic hedgehog (Shh) and Dickkopf-related protein 1 (Dkk1) that mimics embryonic intestine-stomach specification. These induced-stomach primordiums had Barx1-expressing stomach specific mesoderm and Sox2-expressing endoderm in three-dimensional structure imitates embryonic stomach tissue in vivo. Furthermore, induced-stomach primordiums could differentiate into three morphological stomach parts, forestomach, corpus, and antrum in three-dimensional pro-stomach culture system. The corpus region contained lots of H+/K+ ATPase-expressing parietal cells, and the antrum region contained lots of Pepsinogen-expressing chief cells in each stomach tissue part. Using this culture method as a model to study mouse stomach development and disease model, we identified that Shh induction and Wnt inhibiting are require for stomach specification and three-dimensional culture promotes stomach primordiums into mature stomach tissue in vitro. Lastly, we demonstarated that over expression of transforming growth factor-α (TGFα) increased the number of mucocus cells in stomach tissue using Rosa26 Tet-knock in system resembles " Menetrier diease" morphology in vitro. In conclusion, embryonic stem cells derived stomach tissue should allow for unprecedented studies of stomach development and human stomach disease model in the future.

AN EPIGENETIC BASIS FOR LATERAL INHIBITION IN INTESTINAL STEM CELL DIFFERENTIATION

Tae-Hee Kim, Fugen Li, Isabel Ferreiro-Neira, Li-Lun Ho, Annouck Luyten, Kodanda Nalapareddy, Michael Verzi, Ramesh Shivdasani
Dana-Farber Cancer Institute, Boston, MA, United States

It is unclear, at the level of chromatin, if the potential to express diverse transcriptional programs is inherent in adult tissue stem cells or develops as they differentiate along distinctive lineages. In the process known as lateral inhibition, neighboring progenitor cells adopt two mutually exclusive fates: one cell, specified stochastically, transmits a signal that forces its neighbors to adopt a different identity. The two cell fates, however, remain interchangeable for long periods, implying chromatin plasticity at hundreds of genes. Intestinal stem cell (ISC) differentiation into enterocytes or secretory (goblet, endocrine, and Paneth) cells is attributed to Notch-mediated lateral inhibition among their immediate bipotential progeny. Expression of the transcription factor ATOH1 and Delta-like ligands in a few cells leads them to adopt the secretory fate and signal to Notch receptors in neighboring cells. This signaling activates HES1, a transcriptional repressor that prevents *Atoh1* expression and secretory differentiation in recipient cells, forcing the enterocyte fate. To investigate the epigenetic and transcriptional basis of this process, we purified Lgr5+ ISCs and absorptive and secretory progenitors from mouse intestinal crypts. mRNA expression profiles

of the isolated populations verified their respective potentials and identified lineage-specific genes. Genome-wide analysis of ATOH1 binding in secretory progenitors and *Atoh1*-dependent transcripts implicated this transcription factor in direct control of both lateral inhibition and secretory differentiation, through its binding to *cis*-elements of Delta-ligand genes and key lineage determinants. Despite showing large differences in expressed genes, absorptive and secretory progenitors carried almost identical marks of active chromatin - H3K4me2, H3K27ac, and DNaseI hypersensitivity, signifying nucleosome displacement -at most genes. Thus, despite cells' overt commitment to one branch of differentiation, their chromatin manifested the potential to activate the transcriptional program of either branch. As evidence for functionality of marked enhancers, depletion of ATOH1 in committed secretory cells *in vivo* was sufficient to convert them into enterocytes. Importantly, enhancers for genes restricted to each mature lineage were well-delineated and showed early signs of activation in Lgr5+ ISCs, generating a broadly permissive chromatin state. Thus, lateral inhibition in the intestine is driven by direct activity of a lineage-specific transcription factor operating in a permissive chromatin state that is established in multipotent stem cells. These findings explain a fundamental differentiation mechanism with respect to chromatin states and elucidate the basis for lineage plasticity in ISCs and their immediate progeny.

PRETREATMENT WITH TLR LIGANDS ENHANCES THE IMMUNOSUPPRESSIVE CAPACITY OF MESENCHYMAL STEM CELLS IN ANIMAL MODEL OF PROCTITIS

Christine Linard, Jean Victor Lacave-Lapalun, Marc Benderitter
IRSN, Fontenay aux roses, France

Augmenting tissue repair by the use of mesenchymal stem cells (MSCs) may be an important advance in treating radiation-induced proctitis. The immunosuppressive capacity of MSCs was become a key factor for their therapeutic use and potency. Recently reported that TLR ligands can improve the MSCs capacity to suppress immune responses and repair. Using a colorectal model of 27Gy irradiation in rats, we investigated the effects of *i*) systemic MSCs (5.10^6) administration (rat MSCs) *ii*) TLR5 ligand flagellin administered (3 days post-irradiation) prior the systemic MSCs administration (rat flagellin pre-treatment) or *iii*) MSCs preconditioned 24h in culture with flagellin (rat Flag-MSC). MSCs or Flag-MSCs were administered 7 days post-irradiation. At 28 days post-irradiation, histopathological lesions are similar to those seen clinically (severe acute mucosal ulceration, large immune cell infiltration. Flow cytometric analysis of isolated colonic immune cells population showed that MSCs, Flag-MSC treatment and MSCs injected after flagellin pre-treatment reduced significantly the innate immunity response (neutrophil and macrophage infiltration) as compared to irradiated rats. Although the among of natural killer cells was not decrease by MSCs, Flag-MSC and flagellin pre-treatment, RT-PCR assays showed that Flag-MSC and flagellin pre-treatment induced INOS overexpression, crucial to achieve immunosuppression. Analysis of the $CD4^+$ and $CD8^+$ T cells frequency revealed that MSCs, Flag-MSCs and flagellin pre-treatment did not modified the enhanced $CD4^+$ frequency in the irradiated colonic mucosa; on the other side the CD4/CD8 ratio decreased with MSCs, increase with flagellin pre-treatment and, in opposite was normalized with Flag-MSCs compared to irradiated rats. Surprisingly, in the irradiated colonic mucosa no modification of the suppressive T-cell population Treg ($CD4^+CD25^+$) was induced by MSCs alone as compared to irradiated rats, but Flag-MSC and flagellin pre-treatment overexpressed FOXP3 and IL-2Rα which characterized an enhanced functional Treg phenotype. Specifically, IL-10 was overexpressed with Flag-MSCs. In addition, MSCs, Flag-MSCs and flagellin pretreatment, in the same manner, restored the epithelial cell proliferation (characterized by Ki67 overexpression) and the antimicrobial Reg3γ protein implicated in host defense. In conclusion, on a proctitis model, MSCs exposed to activation through TLR5 ligand (pre-activation of the host or pretreated-MSCs) have an enhanced immunosuppressive capacity.

W-1107

A HUMAN IPSC MODEL OF FAMILIAL ADENOMATOUS POLYPOSIS

Cesar A. Sommer, Andreia Gianotti Sommer, Gustavo Mostoslavsky

Center for Regenerative Medicine (CReM), Boston University School of Medicine, Boston, MA, United States

Mutation of the Adenomatous Polyposis Coli (APC) tumor suppressor gene underlies Familial Adenomatous Polyposis (FAP) and is an early event in most colorectal adenomas and carcinomas. APC is a multidomain protein controlling fundamental cellular processes that include intestinal cell migration and proliferation, spindle formation, and chromosome segregation. We developed an in vitro model of FAP by generating induced pluripotent stem cells (iPSCs) from fibroblasts isolated from individuals carrying germline mutations in APC. The FAP-iPSC lines were induced to form intestinal tissue by directed differentiation, resulting in 'intestinal organoids' resembling normal intestinal epithelium with expression of typical gut markers. Cell proliferation, Wnt target gene expression and cell polarity assays were performed in iPSCs and their differentiated progeny. To investigate the functional effects of biallelic APC inactivation in FAP-IPSCs, we designed and assembled Transcription Activator-Like Effector Nucleases (TALENs) targeting codon 1309 in the mutation cluster region of APC. Our results provide a platform for elucidating disease mechanisms underlying FAP with possible future applications in high-throughput drug screening.

BONE MARROW CELLS EXPRESSING CLARA CELL SECRETARY PROTEIN ARE CAPABLE OF FORMING FUNCTIONAL CONNEXIN CHANNELS WITH MATURE EPITHELIAL CELLS.

Paula Marcus, Pascal Duchesneau, Rickvinder Besla, Thomas K. Waddell
Latner Thoracic Surgery, UHN, Toronto, ON, Canada

Background: Bone marrow (BM) may contain populations of stem and progenitor cells required for the repair of many tissues. Previous data has indicated the presence of a population of bone marrow cells that express the airway marker Clara cell secretary protein (CCSP) and that these cells are capable of re-populating the airway after injury. However, the exact role these cells in repair is unclear. The aim of this work is to determine if the CCSP+ BM cells are capable of communicating with mature epithelial cells via the formation of connexin (Cx) channels.
Materials and methods: BM cells expressing CCSP were isolated from C57Bl/6 mice by flow cytometry after 7 days in culture. The expression of airway related Cx molecules (Cx 43, 32 and 26) was determined through quantitative PCR (qPCR). The presence of Cx channels *in vivo* was examined by immunofluorescence microscopy following transtracheal delivery of CCSP+ BM cells in a mouse model of airway injury naphthalene. Finally, the presence of functional communication was evaluated by labelling CCSP+ cells with the membrane dye PKH26
(Sigma) and calcein-AM (Invitrogen), a dye that can be transferred through Cx channels. Labelled cells were either mixed with the bronchial epithelial cell line Beas-2b, or delivered intratracheally to 8 week old mice. To ensure specificity of dye transfer, controls where Cx channels were blocked with carbenoxolone (Sigma) were included.
Results: CCSP+ BM cells expressed epithelial specific Cx molecules,
and stained positively for Cx43. The CCSP+ BM cells were retained in the airway after delivery into a naphthalene injured mouse. These cells appeared capable of forming connexin channels with airway cells, as indicated by Cx43 labelling at the periphery of the delivered cells. However, to determine if the CCSP+ BM cells could communicate we looked at dye transfer between epithelial cells and the BM cells. Dye transfer occurred *in vitro* between the two populations, and this transfer could be reduced with the addition of a gap junction block. Preliminary data also suggests that these CCSP+ cells are capable of transferring dye *in vivo* to airway cells as early as 4 hours after delivery.
Conclusions: CCSP+ BM cells are capable of expressing the required elements for gap junction communication, both *in vitro* and *in vivo*. Moreover, the cells can also form functional Cx channels with mature epithelial cells, as indicated by the ability to transfer dye. This suggests that the CCSP+ BM cells are able to interact with epithelial cells within the airway after injury, and it is possible that the formation of these channels is important in the repair response.

GENERATION OF AIRWAY AND LUNG EPITHELIAL CELLS FROM HUMAN PLURIPOTENT STEM CELLS

Sarah Xuelian Huang, Ya-wen Chen, Melanie Mumau, Hans-Willem Sneock
Medicine/CCTI, Columbia University, New York, NY, United States

Generation of airway and lung epithelial cells from human pluripotent stem cells

Sarah X.L. Huang[1], Ya-Wen Chen[1], Melanie Mumau[1], Hans-Willem Snoeck[1]
[1]Columbia Center for Translational Immunology, Columbia University Medical Center, New York, NY, USA

Rationale: Directed differentiation of human pluripotent stem cells (hPSCs) *in vitro* towards lung progenitors, using a defined combination of morphogens, following developmental paradigms, should be able to recapitulate lung development *in vivo*, allow generation of human lung and airway epithelial cells with high efficiency.

Significance: Efficient directed differentiation of hPSCs into most types of lung and airway epithelial cells has not been achieved thus far[1-3]. Yet, the ability to generate such cells from hPSCs has applications in regenerative medicine for lung diseases, drug screening and disease modeling, and provides a model to study human lung development[4].

Aims:

1. To generate early human lung progenitors from hPSCs with high purity.
2. To further mature the early lung progenitors into a variety of airway and lung epithelial cells that express lineage-specific markers.

Methodology: The aims were achieved through a strategy involving hierarchal, sequential, and stepwise induction of definitive endoderm[5], followed by generation of anterior foregut endoderm[4] that is specified with high efficiency towards $NKX2.1^{+}FOXA2^{+}$ developmental lung field progenitors, and subsequent long-term differentiation into cultures where most markers of lung and airway epithelial cells are expressed in varying ratios. The expression of lineage specific phenotypic markers at each differentiation stage was examined at both mRNA and protein levels.

Results: We developed, based on developmental paradigms, a highly efficient method for directed differentiation of hPSCs into early lung progenitors where ~95% of the cells were $FOXA2^{+}$, and where 80-90% of $FOXA2^{+}$ cells expressed NKX.2.1 (Fig. 1a).

Prolonged culture of the early lung progenitors until d48 induced most markers of airway and respiratory epithelial cells. These markers included mucins (MUC1, MUC5AC, MUC2, MUC5B) (Goblet cells), ample expression of CC10 (Clara cells), a secreted protein that was also detected outside of cell boundaries, FOXJ1 (ciliated cells), proSP-C and SP-B (ATII cells) as well as AQ5 and PDN (putative markers of ATI cells) (Fig. 1b).

Conclusions: This report is the first to show full differentiation of hESCs into a wide array of lung and airway cells, such that most cells in the culture could be assigned to a type of respiratory epithelial cell. Currently, we are trying to develop assays/models to test the function of the lung and airway epithelial cells.

MESENCHYMAL STEM CELLS STIMULATE BRONCHIOALVEOLAR STEM CELL DIFFERENTIATION

Kristen T. Leeman[1], Carla Kim[2]
[A]Department of Newborn Medicine, [B]Department of Hematology Oncology, [1]Boston Children's Hospital, Boston, MA, United States

Background: Bronchopulmonary dysplasia (BPD) remains a major complication of prematurity resulting in significant mortality. BPD includes alveolar epithelial simplification and distal lung injury. Treatment with bone marrow derived mesenchymal stem cells (MSC) and MSC-conditioned media ameliorated lung parenchymal and vascular injury in the hyperoxia murine model of BPD. It is possible that the beneficial response from the MSCs is partly due to activation of endogenous lung epithelial stem cells. Bronchioalveolar stem cells (BASCs) are an adult lung stem cell population capable of self-renewal and differentiation in culture, and BASCs proliferate in response to bronchiolar and alveolar lung injury in vivo. Systemic treatment of neonatal hyperoxia-exposed mice with MSCs or MSC-CM significantly increased BASCs compared to untreated controls. Treatment of BASCs with MSC-CM in 2D culture showed an increase in growth efficiency, indicating a direct effect of MSCs on BASCs.

Hypothesis: We hypothesize that distal lung stem cells contribute to repair and regeneration in neonatal lung injury.
Design/Methods: We established a new 3D matrigel assay to assess BASC differentiation potential after exposure to MSCs. FACS isolated BASCs (CD31-CD45-EpCAM+Sca1+ cells) from β-actin GFP mice were mixed with growth factor reduced matrigel and MSCs or control stromal cells, lung primary mouse endothelial cells (MECs). Cell mixtures were plated on transwell inserts and standard media was added to the bottom of the plate. 14 days after plating, cultures were examined for heterotopic
colony formation including bronchiolar colonies, alveolar colonies, and colonies with mixed phenotype, the later of which retain progenitor activity. Hematoxylin and eosin (H&E) staining and immunofluorescence for CCSP and SPC confirmed colony differentiation type.
Results: MSCs significantly increased BASC colony numbers 2.8-fold compared to co-culture with MECs (p=0.04). Colonies arising in MSC co-culture were significantly larger compared to controls; 41% of colonies with MSCs were large or medium vs 22% in controls. These data support our hypothesis that MSC-secreted factors enhance BASC function. BASC/MSC co-cultures trended towards more bronchiolar and alveolar colonies compared to BASC/MEC cultures with more prevalent mixed phenotype colonies. This may indicate MSC factors stimulate BASC proliferation and differentiation, whereas MEC factors foster maintenance of progenitor cells.
Conclusions: BASCs may play a role in the repair of alveolar lung injury in BPD and in the restoration of distal lung cell epithelia. MSCs and MSC-derived factors may stimulate BASC differentiation and enhance repair of neonatal lung injury.

W-1114

EFFECTS OF FIBROBLAST GROWTH FACTOR 9 ON STEM CELLS OF UPPER AIRWAYS

Ahmed E.M. Hegab[1], Daisuke Arai[1], Kenzo Soejima[1], Steven L. Brody[2], David M. Ornitz[2], Tomoko Betsuyaku[1]
[1]Keio University School of Medicine, Tokyo, Japan, [2]Washington University School of Medicine, St. Louis, MO, United States

RATIONALE:
Many of the fibroblast growth factors (FGFs) are reported to promote self-renewal, proliferation and inhibition of cellular senescence mainly through effect on tissue-associated stem cells. FGF-9 is a secreted signaling molecule that is required for lung development and is highly expressed in a subset of human lung adenocarcinomas. However, specific function of FGF-9 and its effect on adult tracheal basal stem cells are unknown.
METHODS:
We used both two- and three-dimensional primary culture systems, the air-liquid interface (ALI) and stem cell sphere-formation system, respectively, to examine the effect of FGF9 treatment on the behavior of mouse tracheal epithelial cells (mTEC). In both assays, cells were treated with FGF9 10-300 ng/ml for 1-3 weeks. ALI preparations were assayed for cell proliferation and differentiation by immunostaining. Stem cell spheres were assayed for sphere number, size, differentiation and self-renewal.
RESULTS:
Immunostaing of ALI preparations for tracheal epithelial cell and proliferation markers (cytokeratin 5 and TRP63 for basal cells, CCSP for Clara cells, acetylated β-tubulin for ciliated cells and PCNA to detect proliferating cells) revealed that FGF9 induced the rate of basal cell proliferation in a dose-dependent fashion. Low and medium doses of FGF9 treatment did not affect differentiation of basal cells into Clara and ciliated cells while high dose FGF9 resulted in an increase in basal and a decrease in Clara cells; i.e., basal cell hyperplasia. FGF9 treatment significantly increased average sphere diameter and the number of spheres per well, compared to control treatment, indicating potentiation of stem cell self-renewal and increase activation or decrease senescence of stem cells.
CONCLUSION:
FGF9 accelerates the self-renewal of basal stem cells and in higher doses suppress their differentiation into the secretory lineage. This finding suggests a potential role of FGF9 in repair or tumorigenesis in adult lungs.

ABROGATION OF SIX1/EYA1 DISRUPTS THE SACCULAR PHASE OF LUNG MORPHOGENESIS AND CAUSES REMODELING

Karol Lu[1], Raghava Reddy[1], Barbara Driscoll[2], David Warburton[2], Ahmed El-Hashash[2]
[1]Children's Hospital Los Angeles (CHLA), Los Angeles, CA, United States, [2] Children's Hospital Los Angeles (CHLA) and University of Southern California, Los Angeles, CA, United States

The Eya1 gene encodes a transcriptional co-activator that acts with Six1 gene to control the development of different organs. However, Six1-Eya1 genetic interactions and functional roles in lung remodeling in premature infants with bronchopulmonary dysplasia (BPD) are still unknown.
Objective: Determine the functional role of Six1-Eya1 genetic interactions in lung remodeling in premature infants with bronchopulmonary dysplasia (BPD).
Hypotheses: Based on the premise that Eya1 and Six1 genes regulate development of different organs and differentiation of various progenitor cells, we assume that Six1-Eya1 genetically interacts to synergistically regulate lung morphogenesis, and their loss results in a pre-BPD-like saccular phenotype. We further postulate that TGF-β signaling pathway is involved in the development of pre-BPD-like saccular phenotype.
Materials and Methods: Lungs of compound homozygous (Eya1-/- or Six1-/-) and heterozygous mice and histological sections of E14.5 and E18.5 were used to examine phenotypic characteristics. The relationship between Eya1 and Six1 was determined by co-immunoprecipitation, Western blot assays and in vitro knockout of Six1 followed by overexpression of Eya1 in MLE15 cells.
Results: We found that pathological changes in Eya1-/- or Six1-/- mice bore similarities to premature infants born in the saccular phase who develop BPD, including mesenchymal thickening, remodeling of the distal lung septae and arteries as well as abnormal capillary development. Thus, mutant lung histology at the saccular phase shows abnormal lung morphogenesis, characterized by mesenchymal and saccular wall thickening, abnormal proliferation of α-smooth muscle actin-positive cells, increased mesenchymal/fibroblast cell differentiation and poor capillaries development, which become more severe when deleting both genes.
Conclusion: Our study indicates that SHH but not TGF-β signaling pathway is a central mediator for the histologic alterations described in association with pre-BPD-like saccular phenotype in Eya1-/- or Six1-/- lungs. Indeed, genetic reduction of SHH activity in vivo or inhibiting its activity in vitro substantially rescues the pre-BPD-like phenotype in mutant mice at the saccular phase, providing the first evidence for the potential involvement of SHH signaling in BPD. These findings uncover novel functions for Six1-Eya1-SHH pathway in the development of BPD-like saccular phenotype, providing a conceptual framework for future mechanistic and translational studies in this area.

Epidermal Cells

INTRADERMAL ADIPOCYTES MEDIATE FIBROBLAST RECRUITMENT DURING SKIN WOUND HEALING

Barbara Schmidt, Valerie Horsley
MCDB, Yale University, New Haven, CT, United States

The communication of multiple cell types in the skin is essential for epidermal and dermal repair following acute wounding. Interaction between hematopoietic cells, keratinocytes, and fibroblasts has been studied extensively during skin wound healing, as these cell types must proliferate and migrate to restore a functional skin barrier. However, the possible roles for other cell types within the skin, such as the intradermal adipocytes, have not been investigated during skin regeneration. Here, we present data demonstrating that adipocyte lineage cells are activated and repopulate skin wounds after injury. We find that adipocyte repopulation occurs after the immune response and in parallel with fibroblast migration. Functional analysis of mice with defects in adipogenesis demonstrates that adipocytes are necessary for the recruitment of fibroblasts into the wound bed and subsequent reconstruction of the dermis. Interestingly, these data reveal that initial re-epithelialization can occur in the absence of

fibroblast recruitment but cannot be maintained, resulting in wound failure. These data implicate adipocytes as a key component of the intercellular communication that mediates fibroblast function during skin wound healing.

W-1122

INDISPENSABLE ROLES OF BNIP3, AN INDUCER OF AUTOPHAGY, IN BOTH DIFFERENTIATION AND MAINTENANCE OF EPIDERMAL KERATINOCYTES.

Mariko Moriyama, Junki Uda, Hiroyuki Moriyama
Kinki University, Higashi-Osaka, Japan

The skin epidermis is a stratified epithelium. Stratification is a key process of epidermal development. During epidermal development, the single layer of basal cells undergoes asymmetric cell division to stratify, and produce committed suprabasal cells on the basal layer. These suprabasal cells are still immature, and sustain several round of cell divisions to form fully stratified epithelia. Recent studies have clarified a numerous number of molecules involved in epidermal development, although it remains elusive how these molecules are coordinated to undergo proper stratification of the epidermis. Autophagy, a lysosomal degradation pathway, is involved in differentiation of erythrocytes, lymphocytes, and adipocytes. Keratinocyte differentiation is also going along with activation of lysosomal enzymes and organelle clearance, expecting the contribution of autophagy in this process.
Previously, by integrating both loss- and gain-of-function studies of Notch receptors and their downstream target Hes1, we show multiple roles of Notch signaling in the regulation of transit amplifying cells in suprabasal layers. Notch signaling induces differentiation of suprabasal cells via Hes1 independent manner, whereas Hes1 is required for maintenance of the immature status of suprabasal cells by preventing premature differentiation. In this study, we found that Hes1 directly suppressed the expression of Bnip3, whose expression is sufficient to induce terminal differentiation of keratinocytes by induction of autophagy.
Chromatin immunoprecipitation assay revealed that HES1 could directly bind to *BNIP3* promoter to suppress the expression. We also found that BNIP3 was expressed in the granular layers, just above the layers where Hes1 expression was observed. Consistent with the BNIP3 expression, autophagosome formation was observed in the granular layer of human epidermal equivalent reconstituted from GFP-LC3 expressing keratinocytes. Forced expression of BNIP3 in human primary epidermal keratinocytes (HPEK) resulted in keratinocyte differentiation, whereas knockdown of BNIP3 had an opposite effect. Intriguingly, addition of an inhibitor of autophagy, 3-methyladenine, significantly suppressed the BNIP3-stimulated differentiation of keratinocytes, suggesting that autophagy is involved in this process. Moreover, we also found that overexpression of BNIP3 induced autophagy in HPEK. These data clearly suggest that BNIP3 plays a crucial role in keratinocytes differentiation by inducing autophagy. Furthermore, dead cells were increased in human epidermal equivalent from BNIP3 knockdown keratinocytes, which gave us the idea that BNIP3 is also indispensable for maintenance of skin epidermis. To test the hypothesis, HPEK were irradiated with UVB. UVB irradiation stimulated BNIP3 expression and cleavage of caspase3. Surprisingly, suppression of BNIP3 expression induced by UVB irradiation caused a further increase of the cleaved caspase3 protein level, suggesting that BNIP3 has a protective effect against UVB-induced apoptosis in keratinocytes. Overall, our data shed light on functions of BNIP3, an inducer of autophagy, in both differentiation and maintenance of epidermal keratinocytes.

TOWARDS UNDERSTANDING THE ROLE OF HOXB7 IN THE SKIN

Fadi P. Jacob, Aiko Sada Nishimura, Tudorita Tumbar
Molecular Biology and Genetics, Cornell University, Ithaca, NY, United States

Epidermal stem cells are known to exist in a specialized niche of the hair follicle known as the bulge, but whether or not all cells of the bulge are of equal potential still remains an important question.
Microarray data displayed clear differences in gene expression between bulge and non-bulge cells, and Hoxb7 was among the genes up-regulated in the bulge. Hoxb7 is a sequence-specific transcription factor of the homeobox fam-

ily that is involved in cell proliferation and differentiation, and has known functions in the developmental regulatory system that provides cells with specific positional identities on the anterior-posterior axis. To investigate the potential role of Hoxb7 in epidermal tissue, we analyzed Hoxb7 expression and lineage activity using two transgenic mice: a Hoxb7-IRES-GFP reporter strain and a Hoxb7-cre/Rosa26-LacZ strain where cre activity in Hoxb7-expressing cells enabled lacZ reporter expression not only in cells that express Hoxb7, but also in their progeny. Surprisingly, we were unable to detect GFP expression in the skin epidermis as we expected from our microarray results and QRT-PCR data for Hoxb7 mRNA levels. Instead, the Hoxb7-IRES-GFP mice showed bright GFP expression in the dermal papilla of the hair follicles and dim GFP in dermal cells. The dermal cells surrounding the hair follicle, especially around the bulge were brighter than the dermal cells located elsewhere. This suggested that the Hoxb7 promoter region utilized for this transgenic might be insufficient to fatefully recapitulate Hoxb7 endogenous expression in the skin, and was potentially influenced by chromosome insertion position effects. The Hoxb7-cre/Rosa26-LacZ mice were analyzed at various stages in embryonic development, as well as in newborn and adult mice during the telogen, anagen, and catagen phases of the hair cycle. An interesting striped pattern of lacZ expression emerging at E14.5 on the back skin was observed in whole-mount tissue. In tissue sections, lacZ expression was detected in several patches of the skin and in various areas of the hair follicle depending on the cycle. Expression in the bulge, as well as other areas of the hair follicle at telogen, followed by expression in patches of the anagen follicle suggested that stem cells in the bulge of some follicles were labeled by the reporter system at some point in development. We hypothesize based on this data that Hoxb7 may play a role in skin patterning and proliferation.

THE INTERFOLLICULAR EPIDERMIS HOMEOSTASIS IS MAINTAINED BY A HAIR FOLLICLE DERIVED STEM CELL IN A HIERARCHICAL MANNER

Edwige Roy[1], Zoltan Neufeld[2], Luca Cerone[2], Angeline Wong[1], Samantha Hodgson[1], Inna Tabansky[3], Kevin Eggan[3], Jean Livet[4], **Kiarash Khosrotehrani**[1]

[1]Experimental Dermatology Group, University of Queensland Centre for Clinical Research, Brisbane, Australia, [2]Department of mathematics and physics, University of Queensland, Brisbane, Australia, [3]Dept of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States, [4]Institut de la Vision, Paris, France

Despite the success of epidermal stem cell therapy, many questions remain on their true potency in steady state conditions. Indeed, the maintenance of the interfollicular epidermis (IFE) remains a controversial subject. Conflicting studies support the existence a stem cell hierarchy in the IFE or a committed progenitor activity without a specific hierarchy. However, recent results revealed a second population of slow-cycling stem cells besides CPs. We hypothesized that those conflicting studies could be resolved using the rainbow technology to label keratin 14-expressing keratinocytes. We generated transgenic mice containing a Brainbow-1.0 cassette under the control of a ubiquitous promoter allowing the random expression of dTomato (red), Cerulean (blue) or eYFP (yellow) upon cre recombination. When crossed with K14-Cre/Esr transgenic mice, this allowed us to induce recombination in all basal keratinocytes regardless of their anatomical location and to follow their fate over time.
To address the role of stem cells, we conducted short and long term experiments at 3, 5, 12 and 24 weeks. Clones within the IFE of dorsal skin grew in size from 3 weeks to 6 months ($p<0.001$) in accordance with the committed progenitor model. To understand the lineage relationship between the CP and these potential stem cells, we analysed the size of clones relative to their positioning and we observed those that were attached or contained a hair follicle were significantly larger ($p<0.05$) and grew more steadily overtime ($p<0.0001$).
Further investigations showed that clones in areas of active hair cycling were larger compared to clones not attached to HF ($p<0.05$) and that proliferation in the HF infundibulum was hair cycle dependent and occurred mainly in anagen ($p<0.0001$) suggesting that this hair cycle phase promoted the growth of IFE clones via a HF contribution. We proposed a model where stem cell populations in HF generated CPs around them which behaved with random fate decision. Using this model, computer simulations integrating 6 colour staining and animal growth predicted clone sizes that closely matched our observations.

In conclusions, Rainbow technology allows the long term tracking of clones derived from individual stem cells. Our results support a hierarchical contribution of hair follicle stem cells to dorsal IFE by differentiating into committed progenitors. Our findings and our proposed model reconcile recent and previous studies showing the importance of the upper portion of the HFs for IFE homeostasis in murine dorsal skin.

BAF53A ENFORCES THE EPIDERMAL PROGENITOR STATE BY SUPPRESSING SWI/SNF-DEPENDENT INDUCTION OF KLF4

Xiaomin Bao[1], Jiong Tang[2], Vanessa Lopez-Pajares[1], Shiying Tao[1], Kun Qu[1], Gerald Crabtree[2], Paul Khavari[1]
[A]Dermatology, [B]HHMI, [1]Stanford University, Stanford, CA, United States

Somatic progenitors suppress differentiation to maintain tissue self-renewal. While epigenetic regulators of DNA and histone modifications can support such repression, a role for nuclear actin-like proteins, such as ACTL6a/BAF53A, is unclear. Here we show that ACTL6a associates with the SWI/SNF chromatin-remodeling complex to suppress differentiation in epidermis. ACTL6a was found enriched in progenitors and down-regulated during differentiation. ACTL6a loss in murine and human tissue abolished epidermal self-renewal and induced terminal differentiation, whereas ectopically expressed ACTL6a suppressed differentiation. Among known activators of epidermal differentiation, KLF4 controls 48.6% of ACTL6a regulated genes. ACTL6a loss upregulated KLF4 and dysregulated KLF4's target genes, effects that were blocked by KLF4 depletion. Furthermore, we show that the SWI/SNF complex regulates KLF4 activation and differentiation, and ACTL6a loss led to enhanced SWI/SNF binding to the promoters of KLF4 and other differentiation genes. ACTL6a thus maintains the undifferentiated progenitor state, partly by suppressing SWI/SNF complex-enabled induction of KLF4.

W-1126

SYNCHRONIZING EFFECT OF CELL-AUTONOMOUS CIRCADIAN CLOCK ON CELL CYCLE IN TRANSIENT AMPLIFYING EPITHELIAL PROGENITORS OF HAIR FOLLICLE

Maksim Plikus[1], Christopher Vollmers[3], Amandine Chaix[3], Damon de la Cruz[4], Raul Ramos[2], Satchidananda Panda[3], Cheng-Ming Chuong[4]
[A]Developmental and Cell Biology, [B]Department of Developmental and Cell Biology, Sue and Bill Gross Stem Cell Reseach Center, [1]University of California, Irvine, Irvine, CA, United States, [2]Salk Institute for Biological Studies, La Jolla, CA, United States, [3]Pathology, University of Southern California, Los Angeles, CA, United States

Circadian clock optimizes various physiological processes through their coordination with the rhythmic changes in the environment. Despite significant advances in the field of clock research, circadian regulation of tissue regeneration is not well understood. Hair follicle stands out as a leading example of an organ capable of continuous physiological regeneration. Each hair follicle cycles through the sequential phases of growth, involution and inactivity. Successful progression through these phases requires complex coordination of the epithelial lineage, from stem cells to terminally differentiated keratinocytes. Recently, circadian clock was implicated in regulation of hair follicle stem cells.
Here we explore the role of circadian clock in the highly proliferative transient amplifying hair follicle progenitors, aka matrix cells. We show that in hair matrix cell-autonomous clock generates daily mitotic rhythms, so that numbers of mitotic cells peak in the morning. This cell cycle regulation is accomplished via circadian synchronizing of Cdc2/Cyclin B-mediated G2/M checkpoint. As the result, mouse hairs grow faster in the morning. During morning hours they are also much more sensitive to genotoxic stress, such as gamma-irradiation. Same doses of gamma-irradiation result in significantly greater damage to transient amplifying matrix population and cause more dramatic hair loss in the morning than in the evening.

These results demonstrate how circadian mitotic gating becomes an essential protective mechanism for the highly proliferative subset of cells within regenerating hair follicles. Furthermore, our results can offer new strategies for minimizing or maximizing cytotoxicity of radiation and chemo cancer therapies.

THE ANDROGEN RECEPTOR MODULATES MURINE EPIDERMAL STEM CELL PLASTICITY AND HAIR FOLLICLE LINEAGE FATE

Kai Kretzschmar[1], Denny L. Cottle[2], Pawel J. Schweiger[2], Fiona M. Watt[1]
[1]Centre for Stem Cells and Regenerative Medicine, King's College London, London, United Kingdom, [2]Cambridge Stem Cell Institute, University of Cambridge, Cambridge, United Kingdom

Murine epidermis is composed of three main compartments: interfollicular epidermis, sebaceous glands (SGs) and hair follicles (HFs). Previous work has established that distinct stem cell pools are responsible for maintaining homeostasis of these three compartments during adult life. However, during tissue regeneration or upon genetic manipulation these stem cell populations are able to replenish each other. To study the ability of epidermal stem cells to differentiate into alternative lineages, we have previously described a transgenic mouse model (deltaK5deltabeta-cateninER), in which ectopic hair follicles (EFs) are selectively induced from the SG upon experimental activation of beta-catenin. We now found that beta-catenin induced EF formation in the SG can be blocked through AR activation, which preserves sebocyte fate. Conversely, AR inhibition enhances conversion to the HF lineage. Interestingly, in pre-existing HF simultaneous beta-catenin activation and AR inhibition caused the development of HF cysts resembling HF tumours. Taken together our results indicate that the AR modulates epidermal stem cell plasticity and hair follicle lineage selection.

UNRAVELING THE IMPACT OF IL-1 SIGNALING ON STEM CELL ACTIVATION IN A WOUND HEALING MODEL

Colin Jamora[1], Pedro Lee[2], Deborah Witherden[3], Eve Kandyba[5], Amanda MacLeod[7], Krzysztof Kobielak[6], Wendy Havran[4]
[1]IFOM-inStem Joint Research Laboratory, Institute for Stem Cell Biology and Regenerative Medicine, Bangalore, India, [2]Biological Sciences, University of California, San Diego, La Jolla, CA, United States, [A]Immunology and Microbial Sciences, [B]Immunology and Microbial Science, [3]The Scripps Research Institute, La Jolla, CA, United States, [A]Pathology, [B]Department of Pathology, [4]University of Southern California School of Medicine, Los Angeles, CA, United States, [5]Immunology and Microbial Sciences, The Scripps Research Insitute, La Jolla, CA, United States

The wound healing response is the product of a complex network of intercellular communications that are orchestrated to repair the damaged tissue. A fundamental process mediated by these reciprocal interactions is the mobilization of local stem cells pools to promote tissue regeneration and repair. Using the epidermal caspase-8 conditional knockout as a genetic model of wound healing, we uncovered different modes by which interleukin-1α (IL-1α) rouses the proliferation of stem cells within distinct niches in the skin. Upon release from epidermal keratinocytes in response to a wound, IL-1α is sufficient to trigger dermal fibroblasts to preferentially activate epidermal stem/progenitor cells. In combination with IL-7, it can also stimulate resident dendritic epidermal T cells (γδT-cells), which favor hair follicle stem cell proliferation. Altogether these finding demonstrate the mechanism by which IL-1 signaling marshals multiple cell types to differentially stimulate distinct epithelial stem cell populations in the skin to restore tissue homeostasis.

Epithelial Cells (Not Skin)

RARE SOMATIC CELLS FROM HUMAN BREAST TISSUE EXHIBIT EXTENSIVE LINEAGE PLASTICITY

Somdutta Roy, Phillipe Gascard, Thea Tlsty
Univ of California San Francisco, San Francisco, CA, United States

Extensive studies have demonstrated that repression of $p16^{INK4a}$ (CDKN2A) not only silences a powerful tumor suppressor activity, but also is associated with the acquisition of a plastic state, i.e. the ability of a cell to change phenotypes. In epithelial cells, repression of $p16^{INK4a}$ does not only inactivate cell cycle arrest in response to stress but also allows increased expression of chromatin remodeling proteins that are important for epigenetic plasticity underlying differentiation. The up-regulation of such chromatin remodeling proteins sets the expression pattern of pluripotent cells in Drosophila and inhibits differentiation and dictates the decision between progenitor and differentiated states in murine myoblasts. Furthermore, mice engineered for knock-out of BMI-1, a polycomb protein that inhibits $p16^{INK4a}$ transcription, fail to repress $p16^{INK4a}$ activity and fail to generate hematopoietic and neural stem cells. In light of these observations, we reasoned that repression of $p16^{INK4a}$ might also modulate expression of cell surface markers that could be used for the prospective isolation of stem or progenitor cells.

We identified cell surface markers that allowed direct isolation of rare cells from healthy human breast tissue that exhibit extensive lineage plasticity. This subpopulation has the potential to transcribe plasticity markers, Oct3/4, Sox2 and Nanog at levels similar to those measured in human embryonic stem cells. *In vitro*, *in vivo* and teratoma assays demonstrated that either a directly-sorted (uncultured) or a single cell (clonogenic) cell population from primary tissue can differentiate into functional derivatives of each germ layer, ectodermal, endodermal and mesodermal. In contrast to other cells that have the potential to express Oct3/4, Sox2 and Nanog, these human endogenous Plastic Somatic cells (ePS cells) are mortal, express low telomerase activity, expand for an extensive but finite number of population doublings, and maintain a diploid karyotype before arresting in G1.

Cells with extensive lineage plasticity exist in healthy tissues and evidence for their plasticity is sometimes observed by pathologists in non-diseased tissue. While the vast majority of stem cell/stromal interactions generate the expected tissues, in rare instances, the signals are misconstrued or malfunction. These rare events, described by pathologists as ectopic tissues, consist of normal tissues in abnormal locations, such as bone in the colon and eye, liver in gallbladder and pancreas in brain.

We anticipate that the novel somatic cell population with extensive lineage plasticity characterized here may be used in the future as a non-embryonic resource to study acquisition of pluripotency, self-repair, replacement and complications in regenerative medicine and cancer.

A NOVEL AT-HOOK CONTAINING TRANSCRIPTION FACTOR PROMOTES DIFFERENTIATION OF NEURAL STEM CELLS.

Pia A. Johansson, German Camargo Ortega, Magdalena Götz
Institute for Stem Cell Research, Helmholtz-Center Munich, Munich, Germany

The size an organ is regulated by a tight balance between the self-renewal of stem cells and their generation of amplifying progenitors enlarging the progeny number. This is of particular relevance in brain development. To identify novel factors regulating neural stem cell maintenance versus differentiation we performed genome-wide expression analysis of neural stem cells at different developmental stages (Pinto et al., 2008, Mol Cell Neurosci.) and in the adult (Beckervordersandforth et al., 2010, Cell Stem Cell). We focused our attention of transcriptional regulators that were highly expressed in neurogenic neural stem cells (isolated from the embryonic forebrain, E14 radial glia, and the adult subependymal zone) and comparatively lower in neural stem cells undergoing gliogenesis. This approach yielded several candidates amongst them several AT-hook containing transcription factors, some also comprising the high mobility group. As expected from the arrays, expression of these factors was high in neural stem and progenitor cells in the developing forebrain, but largely absent in the adult brain except in stem cell niches. Towards functional analysis we used in utero electroporation of cDNA plasmids (Gain-of-function) and specific short hairpin RNA constructs (Loss-of-function). In particular, the AT-hook transcription factor lacking a HMG domain potently promoted neuronal differentiation. Already 1 day post electroporation, the proportion Ki67+, Pax6+ NSCs was significantly reduced, while the proportion of postmitotic cells was increased. Three days after electroporation these had differentiated largely into NeuN+ neurons. Conversely, knock-down experiments resulted in a decrease in differentiation as Ki67+ cells were increased, suggesting a vital role in embryonic neurogenesis. Genome-wide expression analysis performed shortly after overexpression or knock-down revealed exciting candidates that are presently investigated.

W-1134

IN VITRO CHARACTERIZED SALIVARY GLAND STEM CELLS RESCUE RADIATION-INDUCED HYPOSALIVATION

Lalitha S S. Nanduri[1], Mirjam Baanstra[1], Ronald P. van Os[2], **Robert P. Coppes**[1]
[1]Cell Biology and Radiation Oncology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]Department of Biology of Aging, European Research Institute for the Biology of Aging, University Medical Center Groningen, Groningen, Netherlands

Salivary glands are often exposed to radiation, during radiotherapy for head and neck cancers resulting in life-long salivary gland impairment, severely reducing the quality of life of the patients. Stem cell therapy may be an option to prevent radiation-induced hypo-salivation.
In mice, we recently showed(1) that transplantation of several types of stem cell marker expressing cells obtained from mouse salisphere are able to rescue radiation-induced hypo-salivation. The aim of this study is to identify the most potent stem cell of the mice salivary gland.
Murine salivary gland derived primary salispheres contain cells expressing CD24/CD29 that could be separated into four subsets; CD24hi/CD29lo, CD24hi/CD29hi, CD24 med/CD29hi and CD24lo/CD29hi cells. To test the self-renewal potential of the subsets 10,000 single cells/well were serial replated in matrigel to form secondary salispheres. Our results show that CD24hi/CD29hi, CD24 med/CD29hi cells have high secondary sphere forming potential with indefinite self-renewal for the CD24hi/CD29hi population. In our 3D matrigel-collagen differentiation matrix single cell derived spheres from all subsets form salivary organoid structures with the CD24lo or CD29lo group forming more lobular acinar like structures, whereas the CD24hi/CD29hi, and CD24med/CD29hi groups forming more ductal structures, suggesting that these populations contains more primitive stem/progenitor cells. Interestingly, all cells derived from spheres after more than 7 self-renewal passages are enriched for CD24hi/CD29hi. Moreover, when transplanted in locally 15 Gy irradiated salivary glands the success ratio of salisphere derived CD24hi/CD29hi cells (10000cells/mouse) in recovering gland function increased with passage number to 100% at passage 13, indicating selection of stem cells through culturing.

In conclusion, mice salisphere-derived cells that have a high expression of CD24 and CD29 have strong stem cell properties as they can self-renew, differentiate to salivary gland structures in vitro and superbly regenerate irradiation-damaged salivary glands in vivo. In vitro passaging of salivary gland cells further enriched this population for stem cells, indicating that this population most likely contains the stem cells of the salivary gland. Potentially this population could be used for stem cell therapy after radiotherapy for head and neck cancers.
Nanduri L.S.Y., Maimets M., Pringle S.A., van der Zwaag M., van Os R.P., Coppes R.P. Regeneration of irradiated salivary glands with stem cell marker expressing cells (2011) Radiotherapy and Oncology, 99 (3), pp. 367-372

PLURIPOTENCY IN FALLOPIAN TUBE AND EPITHELIAL MESENCHYMAL TRANSITION

Farhana Ishrat Ghani[1], Mirjana Kessler[1], Thieck Oliver[1], Susan Jackisch[1], Christina Fotopouolu[2], Thomas F. Meyer[1]
[1]Molecula Biology, Max Planck Institute for Infection Biology, Berlin, Germany, [2]Department of Gynocology, Charite University Medicine, Campus Virchow, Berlin, Germany

Oxidative stress response, inflammation and regeneration during the reproductive years argue for the existence of pluripotent mechanisms in fallopian tube mucosa to facilitate these extensive changes. Also implication of fallopian tube in etiology of ovarian cancer might indicate the existence of stem cells in this organ. We identify stem cell potential within fallopian tube epithelium and establish long term culture in vitro. Monolayer culture was obtained by cultivating mucosal folds in 2D culture and 3D organoid culture system could be established in Matrigel by providing optimal growth conditions with paracrine signaling components. Differentiated spheres, exhibiting all markers of mature, polarized, fallopian tube epithelium, could be propagated in vitro for longer than 4 months, supporting the presence of stem cells as the “engine” of proliferation potential. Active proliferation regions, resembling mucosal folds in tissue, were confirmed by immunohystochemistry. In effort to identify subpopulation of epithelial cells with stem cell capacity we show that sorted Epcam high cells have the highest organoid formation potential in 3D culture by limited dilution organoid culture assay. Other stem cell markers like alkaline phosphatase, Lgr5, CD133 were also expressed in these cells. Furthermore, 2D cultured cells undergo epithelial mesenchymal transition which is the most important event during organogenesis and cancer metastasis. In early passages, epithelial marker E-cadherin is highly expressed and in late passages EMT marker Snail and mesenchymal marker N-cadherin are strongly expressed and cells show mesenchymal morphology. Therefore, fallopian tube is a nice model to study stem cell characteristics and EMT of epithelial cells.

W-1137

CHARACTERIZING PUTATIVE THYMIC EPITHELIAL PROGENITOR CELLS IN THE ADULT MURINE THYMUS

Kahlia Y.P Wong[1], Natalie L. Seach[1], Maree V. Hammett[1], Marco Barsanti[1], Daniel Gray[2], Richard Boyd[1], Ann Chidgey[1]
[1]Monash Immunology and Stem Cell Laboratories, Monash University, Melbourne, Australia, [2]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

The thymus is the primary source of T cells for adaptive immunity, in which thymic epithelial cells (TECs) play a crucial role. Thymic function and naïve T cell output is optimum during the early years of life but progressively declines, resulting in <10% of functional tissue remaining by midlife. The decrease in naïve T cell output leads to compromised immunity in the elderly and is further exacerbated by cytoablative treatments, such as irradiation and chemotherapy in bone marrow transplant and cancer patients.
Strategies to regenerate the thymic microenvironment include sex steroid ablation and growth factor transfusions. However, from a clinical perspective, optimal recovery of the naïve T cell pool remains a challenge. An alternative approach may be to activate resident TEC progenitors/stem cells within the adult thymic microenvironment to mediate internal thymic regrowth and thus, T cell output.

Whilst evidence supports the derivation of cortical (cTEC) and medullary (mTEC) epithelial lineages from a common bipotent progenitor in the postnatal thymus, the identity of these cells remains elusive. Herein we characterize the adult thymic epithelium and demonstrate that progenitor capacity is retained exclusively by a subset of cortical TECs expressing high levels of Sca-1 and low levels of MHC Class II ($cTEC^{lo}$). Using label retention studies, this subset was found to retain BrdU at 6 months post chase and was preferentially localized to the cortico-medullary junction of adult thymic tissue. Adult epithelium grows poorly in 2D culture however, when placed in a 3D Matrigel co-culture system, $cTEC^{lo}$ efficiently formed colonies and repeatedly generated medullary lineage following serial purification and passaging *in vitro*. Furthermore, when combined with embryonic stroma and engrafted under the kidney capsule, reaggregates containing putative cTEC progenitors generated pockets of thymic tissue containing cells of both medullary and cortical lineage *in vivo*. These cells persisted at 12 weeks post-engraftment however long-term serial grafting will be required to assess the self-renewal potential of the $cTEC^{lo}$ subset.

In summary, these findings suggest that progenitor, and possibly stem cell, potential is retained in the $cTEC^{lo}$ subset in postnatal thymic tissue. Further studies will help refine the molecular pathways involved in thymic stem or progenitor cell activation, and potentially contribute to strategies for endogenous repair of thymus function.

Embryonic Stem Cell Clinical Application

W-1142

TRANSPLANTATION OF XENO-FREE, SORTED HUMAN EMBRYONIC-DERIVED NEURAL STEM CELLS INTO THE INTACT AND TRAUMATICALLY INJURED RODENT BRAIN

Daniel L. Haus[1], Eric Gold[1], Harvey Perez[2], Hal X. Nguyen[2], Aileen J. Anderson[3], Brian J. Cummings[3]

[A]Anatomy and Neurobiology, [B]Sue and Bill Gross Stem Cell Center, [C]Physical Medicine and Rehabilitation, [1]University of California, Irvine, Irvine, CA, United States

Traumatic brain injury (TBI) is one of the leading causes of death and disability worldwide, with an estimated 1.7 million individuals affected each year in the United States alone. Limited treatment options exist, which include stabilizing patients after the initial traumatic event as well as providing limited physical and cognitive rehabilitation. However, therapies to facilitate cellular repair and treat the underlying source of TBI-related deficits have remained elusive. Transplantation of human neural stem cells has the potential to afford such repair via multiple mechanisms, including cellular replacement and/or neurotrophic support. Currently, multiple cell transplantation-based clinical trials are on-going for conditions such as amyotrophic lateral sclerosis (ALS) and spinal cord injury. However, human neural stem cell transplantation has not yet been fully evaluated long-term in an appropriate animal model of TBI. Here we report results from the development and subsequent transplantation of Xeno-Free (XF) human embryonic stem cell-derived neural stem cells (hES-NSCs) into the intact and traumatically injured immunodeficient rodent brain. Shef4 and Shef6 XF hES-NSCs expressed markers characteristic of neural stem/progenitor cells in vitro via immunocytochemistry (ICC) and qPCR (e.g. Nestin, Sox2) and retained a normal karyotype. Magnetic sorting (MACS, Miltenyi Biotec) was used to further enrich XF hES-NSCs for a self-renewing stem cell population (CD133+) and remove potential contaminating CD34+ cells of the hematopoietic and endothelial lineages. Multipotency of differentiated CD133+/CD34- Shef6 XF hES-NSCs was confirmed at 28 days in vitro via expression of neural lineage markers (e.g. ß-TubIII, GFAP, and Olig2). Additionally, unsorted and CD133+/CD34- sorted Shef6 XF hES-NSCs differed in cellular morphologies and growth dynamics in vitro, with unsorted cells having increased cytoplasmic volume and a slower rate of expansion. Upon stereotaxic transplantation into the intact immunodeficient NOD-Scid mouse hippocampus, unsorted Shef6 XF hES-NSCs failed to engraft (0/7, 0%) when examined 12 weeks post-transplantation. Conversely, CD133+/CD34- sorted Shef6 XF hES-NSCs engrafted in the intact hippocampus with a high rate of success (10/10, 100%), with a majority of SC121 positive human cells expressing the neuronal marker ß-TubIII at 12 weeks post-transplantation. When transplanted into the traumatically injured Athymic Nude (ATN) rat brain 9 days after a controlled cortical impact (TBI-0310, Precision Systems and Instrumentation, LLC), CD133+/CD34- Shef6 XF hES-NSCs engrafted, migrated, and extended long processes around the injury penumbra as well as into the contralateral hemisphere via the corpus callosum. Human cell projections were found spanning more than

3mm anterior to posterior and 5mm contralateral from the initial injection sites at 8 weeks post-transplantation. In summary, our preliminary data has demonstrated that sorting (CD133+/CD34-) of Shef6 XF hES-NSCs improves cell engraftment and migration in a sub-acute TBI model, and thereby may produce a more clinically translatable cell population. Future studies will aim to further explore contralateral cell migration/process extension and assess the efficacy of cellular transplantation in promoting behavioral recovery after TBI.

W-1143

HUMAN DEVELOPMENTAL CHONDROGENESIS AS A BASIS FOR THE ENGINEERING OF CHONDROCYTES FROM PLURIPOTENT STEM CELLS.

Ling Wu, Brooke Latour, Stephanie Gonzalez, Saumya Shah, Frank Petrigliano, David R. McAllister, **Denis Evseenko**
UCLA, Los Angeles, CA, United States

Articular cartilage is a highly specialized tissue formed from chondrocytes that protects the bones of diarthrodial joints from forces associated with load bearing and impact, and allows nearly frictionless motion between the articular surfaces. Cartilage injury and lack of cartilage regeneration often lead to osteoarthritis currently affecting more than 25 million people in the United States alone, making joint surface restoration a major priority in modern medicine. None of the previously published studies have reported the generation of a highly purified population of pluripotnet stem cells (PSC)-derived chondrocytes, instead demonstrating the generation of a likely heterogeneous population capable of depositing chondrogenic matrix molecules, the cell of origin of which cannot be tracked in these systems. As a result, immunophenotypes and functional characteristics of the earliest cartilage cells derived during differentiation of PSC were not known. To the large extend this knowledge was missing due to the complete lack of the developmental studies dissecting the earliest stages of human chondrogenesis. In this study we have isolated and characterized, for the first time, pre-chondrocytes and chondrocytes at 6-17 weeks of human development. Pre-chondrocytes represent a unique, transitional population of cartilage-committed cells at the earliest stages of articular joint development that gives rise to joint forming definitive peri-articular chondrocytes. Genome wide comparison of pre-chondrocytes isolated at 6 weeks of development with peri-articular chondrocytes in fully formed joints at 17 weeks of human development led to the identification of several markers for immunophenotypic tracing and FACS isolation of both cartilage cell types. The identification of specific molecular signature for the earliest pre-chondrocytes and peri-articular chondrocytes will now permit further delineation of the molecular regulation of the first stages of chondrogenic commitment in humans. It may also contribute to understanding of how these processes are affected during aberrant chondrogenesis in disease states. Finally, characterization of the earliest primary cartilage cells provides essential knowledge for the generation of highly purified chondrocytes from PSC and representing a unique target for cartilage tissue engineering.

MATURATION OF INDUCED NEURONAL CELLS GENERATED FROM ADULT AND POSTNATAL FIBROBLASTS FACILITATED BY SMALL MOLECULES

Cheen Euong Ang, Marius Wernig
Bioengineering, Stanford University, Stanford, CA, United States

Since our lab reported the first direct conversion of mouse and human fibroblasts to induced excitatory neuronal (iN) cells, several groups have since reported using the same four transcription factors (Brn2, Ascl1, Myt1l and NeuroD1) or in combination with other transcription factors or microRNAs to generate other neuronal subtypes. While mouse embryonic fibroblast to iN cell conversion is generally efficient and yields synaptically mature iN cells, the reprogramming efficiency of human postnatal or adult fibroblasts to iN cells hovers around 2% and most resulting neurons are of very immature appearance. Herein, I will describe our efforts in employing a high throughput screening strategy to find small molecule inhibitors or agonists which can improve iN reprogramming efficiency. To date, an inhibitor of the BMP and an agonist of the PKC pathway were found to be helpful in increasing the efficiency of iN reprogramming by up to 2.5 fold for a mere three day drug treatment. Further characterizations using

immunofluorescence showed that the induced neuronal cells are positive for multiple mature neuronal markers as early as 2 to 2.5 weeks post doxycycline induction which is faster than using BAMN alone. These results provide (a) a basis on which further screenings can be done to find other small molecules that act synergistically with the two small molecules and (b) a protocol in which induced neurons can be generated in sufficiently high amount for human disease modelling and drug screening purposes.

W-1145

THE APPLICATION OF MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION (MLPA) AS ROUTINE EXAMINATION METHOD FOR GENETIC STABILITY **OF HUMAN EMBRYONIC STEM CELLS**

Jeoung Eun Lee[1], Sung Han Shim[2], Myung Sun Shim[1], Yuri Kim[1], Sung-Geum Lee[1], Dong Ryul Lee[1]
[1]CHA Stem Cell Institute, CHA Uiversity, Seoul, Korea, Republic of, [2]Dept of Biomedical Science, CHA Uiversity, Seoul, Korea, Republic of

Human Embryonic Stem Cells (hESCs) offer a renewable source for cell based therapy and regenerative medicine by their self-renewal ability and differentiation ability to all kinds of cell type in the body. For clinical application, genetic stability of hESCs should be proven during cultivation and differentiation in the chromosomal level at least. In several studies regarding the chromosomal integrity during long term culture, the most results showed that hESCs were stably maintained after freezing/thawing and long-term culture. But some reported that hESCs had developed chromosomal aberration during in vitro culture. Therefore, hESCs have to be routinely tested at least chromosomal level to verify deleterious changes during maintenance and differentiation. The MLPA is a fast method designed for simultaneous quantification of copy numbers of several dozens of specific genomic sequences. MLPA is easy to perform and requires only 20ng of DNA sample, and is mainly used for diagnosis such as copy number changes of human genomic DNA sequences. Here, we reported the results of genetic stability test by MLPA (SALSA MLPA Kit P070; detection of deletion/duplication) and traditional karyotyping using G-banding in cultivated 10 hESC lines. In early and late passages (cultured for more than 50 passages), chromosomal abnormality of CHA-hES 15, 20, 31, 32, 36, 45, B3 (maintained on mouse feeder cells), 40, 42 (maintained on human feeder cells in xeno-free culture condition), and H1 (maintained on mouse feeder cells) was analyzed by using those two methods. In the present study, the MLPA results corresponded with the karyotyping results. CHA-hES 15, 20, 31, 40, B3 and H1 were 46,XY, and CHA-hES 36 was 46,XX. CHA-hES 32 was 46,XX,inv(9). Interestingly, CHA-hES 42 and 45 were chromosomally abnormal at early passage, 47,XY,+5 and 47,XX,+16 respectively, and then changed spontaneously to normal karyotype during cultivation, 46,XY and 46,XX respectively. It was suggested that the MLPA does not detect polyploidy (like triploid/tetraploid) and translocation, but can detect deletion or duplication of chromosome easily and quickly. Therefore, we may suggest that MLPA analysis can be applicable for routine chromosome analysis of hESCs due to their convenience after MLPA and karyotyping were performed at early stage. Also, when MLPA detected the deletion or duplication, karyotyping should be performed for confirming the genetic abnormality of hESCs.

INEFFICIENT INDUCTION OF HUMAN EMBRYONIC STEM CELLS TO KERATINOCYTE STEM CELLS POPULATION DURING EARLY STAGE OF EPIDERMAL COMMITMENT: A KEY PLAYER IN LIMITED PROPAGABILITY?

Mehdi Mohammad Movahednia, Fahad Karim Kidwai, Yu Zou, Huei Jinn Tong, Tong Cao
Dentistry, National University of Singapore, Singapore, Singapore

Background: Upon first derivation of human embryonic stem cells (hESCs), they attracted lots of excitements, concentrated in developmental research models and future regenerative therapies, due to their unique ability to differentiate into all 3 germ layers *in vitro*. Successful hESCs differentiation toward particulate lineage can be achieved through exposure to selective growth factors and/or by providing a co-culture system with specific inducing lineage. In this notion various differentiation methods toward hESCs-derived keratinocyte (hESCs-Ker) have been reported to provide a pure epidermal population with extended replicative capacity. However, in all of those methods presence of xenogeneic compounds was far from clinically accepted procedures. Recently, we reported the successful

establishment of Autogenic Feeder Free (AFF) system provided by extra cellular matrix (ECM) derived from hESCs-fibroblast, able to provide pure population of hESCs-derived keratinocyte (AFF-Ker) in xeno free environment after 10 days differentiation. However, research and future clinical applications of AFF-Ker system were hampered by their limited propagation (till day 40 day). Therefore, it was our interest to unravel this limited replicative capacity and early senescence in compare to hESCs-Ker, differentiated in presence of feeder. We identified hierarchy of keratinocyte population during differentiation and found that keratinocyte stem cells (KSCs) are the key regulatory factor in hESCs-Ker growth capacity. We speculated that alteration in culture condition during differentiation can increase this population and consequently extends hESCs-Ker propagation.
Methods: hESCs-Ker was provided in two differentiation system, autogenic co-culture (ACC) system in which hESCs cultured on hESCs-fibroblast and autogenic feeder free (AFF) system, utilizing hESCs-fibroblast ECM as a microenvironment. Culture condition alteration performed during 10 days of differentiation in AFF system following by KSCs population quantification by flow cytometry analysis.
Results: Efficient induction to KSCs at early stage of epidermal commitment plays a critical role in hESCs-Ker future growth capacity**.** hESCs-Ker in AFF system posed limited replicative capacity due to the low percentage of KSCs population. Alternatively, KSCs population was found to be significantly higher in propagable hESCs-Ker, in ACC system. Induction to pure population of KSCs in AFF system was performed through culture modification during epidermal commitment. AFF-Ker differentiated in modified condition showed 16±2.4 (SE) population doublings over 70 days with delayed expression of senescence associated β-galactosidase (SA-β-Gal) activity. Moreover, AFF-Ker with extended propagation showed decreased accumulation of cyclin-dependent kinase inhibitor proteins, p16 and p21, concomitant with slower telomere erosion rate.
Conclusion: hESCs-Ker with extended culturing time provided by efficient induction of KSCs at early stage of epidermal commitment. These findings open a new perspective in extending hESCs-derived keratinocyte as an authentic research model. Moreover, this study will enhance the industrial and future clinical application of hESCs-derived keratinocyte.

BETA-CATENIN SIGNALING PATHWAY REGULATES THE NON-TUMORIGENESIS OF HUMAN EMBRYONIC STEM CELLS CULTURED ON HUMAN UMBILICAL CORD STROMAL CELL FEEDERS

Dah-Ching Ding[1], Yu-Hsun Chang[2], Tang-Yuan Chu[3]
[1]Dept of Obstetrics and Gynecology, Buddhist Tzu Chi General Hospital, Tzu Chi University, Hualien, Taiwan, [A]Dept of Pediatrics, [B]Dept of Obstetrics and Gynecology, [2]Buddhist Tzu Chi General Hospital, Hualien, Taiwan

The expansion of pluripotent human embryonic stem cells (hESCs) requires a culture on feeder layers of mouse embryonic fibroblasts (MEF). This culture model often involves immunogenic contamination such as xeno-carbohydrate, and inevitably forms teratoma in vivo. We used human umbilical cord-derived mesenchymal stem cells (HUCMSC) as the feeder for hESCs. Under a mitomycin-inhibited HUCMSC feeder, the hESCs maintained the features of embryonic stem cells (pluripotency, immortality, unlimited undifferentiated proliferation, and maintenance of normal karyotypes) after a prolonged culture of more than 20 passages.
Notably, in extensive trials, no teratomas were formed in xenografts in NOD/SCID mice, however subsequent resumption of teratoma formation was noted upon transient co-culturing with MEF. HUCMSC feeders may confer an “epiblast-like” status on hESCs. Interestingly, among the four pluripotency-conferring genes, MYC was found to be down-regulated in hESCs co-cultured with HUCMSC. We propose that MYC-mediated tumorigenic pathways are down-regulated in hESCs under this coculture model. This means that hESCs on HUCMSC may be reprogrammed to a non-tumorigenic epiblast such as stem cells.
In this study, we found that the β-catenin signaling pathway is an important signaling pathway which regulates the tumorigenicity of hESCs. We demonstrated that the β-catenin antagonist, FH535, could down-regulate β-catenin and c-MYC transcription and translation in vitro. Furthermore, FH535 also reduced the teratoma formation rate of hESCs/MEF in vivo. We also demonstrated that the β-catenin enhancer, LiCl, could up-regulate β-catenin and c-MYC

transcription and translation in vitro. Moreover, LiCl could promote the teratoma formation of hESCs/HUCMSC in vivo.
Based on these findings, we conclude that the WNT/β-catenin pathway is an important but not the only signaling pathway which controls the tumorigenicity of hESCs.

ANGIOPOIETIN-LIKE PROTEIN RECEPTORS STIMULATE HSC DEVELOPMENT THROUGH DIRECT INTERACTION WITH NOTCH.

Michelle I. Lin[1], Emily N. Price[1], Sruthi Satishchandran[1], Charles W. Carspecken[1], Audrey Uong[1], Anthony DiBiase[1], Jon C. Aster[2], Richard M. White[3], Leonard I. Zon[1]

[1]Harvard Medical School, HHMI, HSCI, Hematology/Oncology, Children's Hospital Boston, Boston, MA, United States, [2]Pathology, Brigham and Women's Hospital, Boston, MA, United States, [3]Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, United States

Members of the angiopoietin-like protein (angptl) family have recently been identified as novel growth factors, capable of stimulating ex vivo expansion of mouse and human HSCs. However, their requirement during development and their mechanism of action are still very much unknown. To first recapitulate the effects of exogenous angptl on HSC expansion, we generated a stable heatshock inducible transgenic zebrafish line to overexpresses angptl2 and found that these embryos showed a significant increase in cmyb- and runx1-positive HSCs in the aorta-gonad-mesonephros (AGM) region, the site of definitive hematopoiesis. Conversely, anti-sense morpholino knockdown of angptl1 and 2 resulted in a decrease in cmyb/runx1-positive HSCs in the AGM, suggesting that angptls are sufficient and required for definitive hematopoiesis. These double morphants also displayed a disruption in vascular development and differentiation prior to the defect observed in the AGM, indicating that angptl regulation of HSC development occurs through an early specification of the hemogenic endothelium. Because angptl morphants phenotypes resemble that found in the notch mutant mindbomb, mib, we asked if there is a genetic interaction between notch and angptl signaling. Using a transgenic notch reporter line, we see that knocking down angptl1 and 2 caused decreased notch signaling. Surprisingly, the HSC defects normally observed in mib embryos were rescued when angptl2 is overexpressed, implying that angptl2 acts downstream of mindbomb signaling. When we overexpressed a constitutively active form of notch in angptl1 and 2 double morphants, restored HSC formation was observed. Together, these genetic data corroborated our hypothesis that angptls can regulate notch signaling. To further dissect this relationship, we stimulated cultured human CD34+ cells with purified Angptl2 and found an increase in Notch receptor cleavage, indicating that Angptl2 can induce Notch receptor activation. Through endogenous co-immunoprecipitation experiments in CD34+ cells, we also found that the Angptl receptor, LILRB2, interacted with Notch receptor either in the transmembrane or intracellular region. This strongly indicates a direct regulation of Notch activation/signaling by Angptls through physical interactions between Notch and Angptl receptors. Finally, in order to examine downstream signaling of Angptl-mediated Notch activation, we performed ChIP-seq for Notch in Angptl2-stimulated CD34+ cells and found enrichment for Myc binding elements. Independent microarrays performed from the same cells also revealed a strong Myc signature through GSEA analysis. Thus, to test the hypothesis that myc is a common downstream mediator for angptl and notch signaling, we overexpressed zebrafish myc-b in angptl1 and 2 double morphants or mib mutants, and found a significant rescue in HSCs formation in the AGM. Together, these results indicate that angptl can regulate notch signaling through receptor interaction, leading to activation of myc target genes during definitive hematopoiesis. Our data provide new insights to the previously uncharacterized angptl signaling during HSC development and present a novel mechanism of action for non-canonical notch activation.

HEMATOPOIETIC ENGRAFTMENT OF AMNIOTIC FLUID STEM CELLS FOLLOWING IN UTERO TRANSPLANTATION

Stavros P. Loukogeorgakis[1], Panicos Shangaris[2], Enrica Bertin[4], Panagiotis Maghsoudlou[1], Michael Blundell[3], Luca Urbani[1], Valentina Spinelli[1], Durrgah Ramachandra[1], Adrian Thrasher[3], Michela Pozzobon[4], Anna L. David[2], Paolo De Coppi[1], Paolo De Coppi[1]

[A]Surgery Unit, ICH, [B]Institute for Women's Health, [C]Center for Immunodeficiency, ICH, [1]University College London, London, United Kingdom, [2]Regenerative Medicine Laboratory, University of Padua, Padua, Italy

Background:
Fetal immune tolerance is the most compelling rationale for prenatal stem cell therapy for congenital blood disorders. However, experimental in utero transplantation (IUT) of allogenic hematopoietic stem cells gives limited chimerism in the blood, and maternal humoral and cellular immune responses are thought to be to be responsible for loss of engraftment. Amniotic fluid stem cells (AFSC) are an appealing cell source for IUT as they are autologous to the fetus, non-immunogenic to the mother, and have shown hematopoietic potential when transplanted postnatally. The aim of the present study was to determine whether IUT of autologous (congenic) AFSC would result in hematopoietic engraftment in immune-competent mice.

Methods:
IUT was performed in timed-pregnant wild-type C57BL/6J mice (n=3; CD45.2+). To mimic autologous AFSC IUT, lineage-depleted/c-Kit+ AFSC were isolated at E13.5 from C57BL/6J dams expressing CD45.1 (n=2; CD45.1+; congenic AFSC). IUT was performed at E13.5, and 10,000 freshly isolated AFSC were injected into the peritoneal cavity of each fetus (n=15). Donor cell engraftment in transplanted pups was assessed at 4 weeks of age by flow cytometry as the percentage of CD45.1+ cells isolated from blood and hematopoietic organs. Chimerism was defined as more than 1% (of total) CD45.1+ cells. Bone marrow (BM) derived cells from chimeric pups were used to perform colony-forming assays. Results are expressed as mean±SE.

Results:
Freshly isolated c-Kit+ AFSC expressed pluripotency (c-myc, Klf4, Oct4, Sox2, SSEA1), as well as hematopoietic markers (Sca1, CD34, CD45.1). The miscarriage rate following IUT was 33.3% (5/15) and there were no maternal complications. Chimerism in the blood and BM was observed in 100% (4/4) of transplanted pups at 4 weeks (CD45.1+ cells in blood: 5.8±1.2% of total; BM: 10.9±1.6% of total). Transplanted (CD45.1+) cells contributed significantly to hematopoietic stem cell (7.0±1.3% of CD34+; 7.2±1.9% of c-Kit+) and lymphocyte (8.8±2.2% of CD4+ cells; 11.6±2.0% of CD8+) populations in the blood, and similar results were observed in BM (18.1±1.8% of CD34+; 15.2±0.8% of c-Kit+; 19.4±1.7% of CD4+; 12.7±1.2% of CD8+). Moreover, there was substantial engraftment in other haematopoietic organs including the thymus (CD45.1+ cells: 10.4±5.3% of total; 38.5±6.8% of CD34+; 39.3±5.3% of c-Kit+; 38.8±5.4% of CD4+; 41.5±2.3% of CD8+), spleen (5.2±1.0% of total) and liver (4.3±0.3% of total). Colony forming assays of BM cells from chimeric pups (n=2) demonstrated formation of hematopoietic colonies (BFU-E: n=18; CFU-GM: n=72; CFU-M: n=15), and CD45.1+ cells represented 6.2±1.2% of the total cells harvested after 12 days of culture.

Conclusion:
Prenatal transplantation of AFSC results in successful hematopoietic engraftment in an immune-competent murine model of autologous (congenic) stem cell IUT. Further work will determine whether these engrafted cells have hematopoietic potential when transplanted secondarily in immune-deficient mice and whether IUT of AFSC is effective for prenatal therapy in murine models of congenital blood disorders.

REGULATORY FUNCTION OF HEMATOPOIETIC STEM/PROGENITOR CELLS THROUGH THE ARYL HYDROCARBON RECEPTOR

Yoko Hirabayashi[1], Byung-Il Yoon[2], Isao Tsuboi[3], Jun Kanno[1], Yoshiaki Fujii-Kuriyama[4], Tohru Inoue[3]

[1]Division of Cellular and Molecular Toxicology, Center for Biological Safety and Research, National Institute of Health Sciences, Tokyo, Japan, [2]Laboratory of Histology and Molecular Pathogenesis, College of Veterinary Medicine, Kangwon National University, Chuncheon, Korea, Republic of, [3]Department of Function and Structural Medi-

cine, Nihon University School of Medicine, Tokyo, Japan, [4]Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan

To elucidate the biological functions of the aryl hydrocarbon receptor (AhR), which transmits various xenobiotic responses, it may be strategically worthwhile to analyze tissue stem cells as a model because the expression level of AhR tends to gradually decrease as stem cells differentiate. Because we have recently found that AhR-knockout (KO) mice show an earlier onset of spontaneous neoplasms and a much shorter lifespan than wild-type mice, AhR is assumed to have a suppressor gene function. In this study, we focus on the biological function of AhR in hematopoietic progenitor cells and the cell cycle regulation of these cells to elucidate the relevant mechanism that may explain such an advantageous function of AhR. In the comparison of AhR-KO mice with wild-type mice, 1) the cell cycle status of hematopoietic stem/progenitor cells (colony forming unit (CFU) granulocyte-macrophage (GM); day 9 CFU in spleen (CFU-S9); and day 13 CFU-S (CFU-S13)) was examined by evaluating cycling stem/progenitor cells with continuous incorporation of bromodeoxyuridine (BrdUrd) *in vivo* for up to 13 weeks followed by exposure to ultra-violet A light to eliminate only BrdUrd-incorporating cells, and 2) comprehensive gene expression analysis of bone marrow cells in the steady state was carried out using an Affymetrix GeneChip® Mouse Genome 430 2.0 Array. As a result, 1) AhR-KO mice showed an increased percent kill (percentage of BrdUrd-incorporating stem/progenitor cells) of CFU-S13 or a decreased percent kill of CFU-GM during the initial 1 hr (S phase fraction); a shortened doubling time of CFU-S9: and an increased percent kill of all the stem/progenitor cells, CFU-GM, -S9, and -S13, at a plateau level (entire cycling fraction). In other words, although those from AhR-KO mice showed different times to reach the plateau level, none of them showed continuously increasing BrdUrd incorporation rate, but maintained the level at least until 13 weeks, as in the wild-type mice, which once reached a plateau level after 8 weeks of age then kept the level until 18 months of age. 2) Three hundred and fifteen probe sets were selected as showing significantly different expression levels between AhR-KO and wild-type mice. Among them, 276 genes including 51 cell-cycle regulators were identified by Ingenuity Pathway Analysis. Moreover, their biological functions, which were considered on the basis of their expression levels, were elucidated as to be related to the acceleration of cell cycle (e.g., up-regulation of bromodomain-containing protein 4 and pim-1, down-regulation of transcription factor 3), suppression of apoptosis (e.g., up-regulation of BCL2-like 1, down-regulation of caspase 7 and Fyn), and tumorigenesis (e.g., down-regulation of mitogen-activated protein kinase 9 /Jun kinase 2, Smad4, and RNA polymerase II, TATA box binding protein-associated factor). Thus, steady-state hematopoiesis is presumed to be suppressed via AhR signaling by a possible physiological ligand, which is as yet not identified in wild-type $AhR^{+/+}$ mice. The possible regulation of hematopoietic stem cells that maintains the fraction of dormant hematopoietic stem cells may have mechanistic relevance in terms of a possible genomic stabilization by AhR, which should be elucidated. Nevertheless, such a deceleration of the cell cycle in hematopoietic stem/progenitor cells contributes to a longer stem cell survival, which may be the reason for the extension of animal lifespan.

ACCELERATIVE EFFECT OF AUTOLOGOUS BONE MARROW ON HEALING OF MANDIBULAR FRACTURES IN MALE DROMEDARY CAMELS

Fahd Al-sobayil[1], FA Ahmed[1], MA Al-hawas[1], NA Aljarbou[1], TM Bakheet[2], Abdullah O. Alawad[3], Mohammed A. Al-darweesh[4], **Saleh Altuwaijri**[4]

[1]Qassim Uiversity, Qassim, Saudi Arabia, [2]Maternity and children hospital, Ministry of Health, Jeddah, Saudi Arabia, [3]King Abdulaziz City for Science & Technology, Riyadh, Saudi Arabia, [4]SAAD Research & Development Center ,SAAD Specialist Hosptial, Alkhober, Saudi Arabia

Recent researches have shown that mandibular fractures are the most common fractures in male camels. Healing of mandibular fracture in camels takes relatively long time in which the animal might die due to its inability to eat. Bone marrow contains many cellular elements that may contribute to fracture repair. Several studies on laboratory animals and humans have shown that injection of bone marrow cells significantly enhances healing of bone fracture. The aim of this study was to investigate the effect of bone marrow cells on the acceleration of mandibular fracture healing in male dromedary camels. In addition to physical examination, bone healing was evaluated by bone biomarkers (formation and resorption) and x-ray imaging techniques. Twenty four mandible-fractured adult male camels were divided into four groups:6 were fixed with interdental wiring technique with injecting bone marrow sample at the fracture line (IWBM), 6 were fixed with interdental wiring without adding bone marrow(IW), 6 were fixed with screws and plates with injecting bone marrow at the fracture line (SPBM), and 6 were fixed with only screws and plates (SP). Autologus bone marrow samples were collected from the tuber coxae (6 Ml) and directly injected at the fracture line on the day of bone fixation surgery (day 0) and 14 days post surgery (day 14). Blood samples were collected weekly and x-ray radiography were performed every 14 days. Bone formation biomarkers including osteocalcin (OC) and bone alkaline phsphatase(BAP) and bone resorption biomarkers including pyridinoline (PYD) and deoxypyridinoline (DPY) crosslinks were determined in the serum samples. The mean levels of calcium and phosphorus were also determined in the serum samples. The time took up for complete fracture healing was significantly shorter in groups using bone marrow compared with those without injecting BM. The levels of OC and BAP were significantly increased in all groups, but they were higher starting at day 14 post surgery in groups with BM compared with those without BM. A positive correlation was observed between x-ray radiographs and the concentration of bone formation biomarkers starting from day 28 post surgery. It was concluded that injecting fresh bone marrow directly on the fracture line was able to accelerate the healing of mandibular fracture in dromedary camels.

REPROGRAMMING HUMAN COMMITTED ERYTHROBLASTS EXPANDED FROM BLOOD TO MULTI-POTENT BLOOD PROGENITORS

Bin-Kuan Chou, Xiaosong Huang, Siddharth Shah, Linzhao Cheng
Institute for Cell Engineering, Johns Hopkins Univ, Baltimore, MD, United States

Despite extensive efforts in the past decades to expand transplantable CD34+ human hematopoietic stem/progenitor cells (HSPCs) that are able to give rise to multiple lineages of human hematopoietic cells after clinical transplantation, more research is still required to achieve ex vivo expansion of human HSPCs. Ex vivo production of transplantable HSPCs from human ES cells and more recently from iPS cells has been actively pursued in the past several years, but so far this approach has proved difficult. This is likely due to the lack of a culture condition enabling self-renewal and/or anti-differentiation of human HSPCs in culture. The concept of cellular fate conversion by the iPS reprogramming factors that convert cells to a self-renewing state may provide a novel route to achieve HSPC expansion. We took a different approach by reprogramming human committed blood mononuclear cells (MNCs) back to HSPCs. To this end, we started with cord blood MNCs that have been cultured under an erythroblast culture condition for 7-10 days. As predicted, the expanded cells are mostly erythroblasts expressing CD36 and CD235a,

able to form erythroid colonies (very few myeloid colonies), and lacking lymphoid and myeloid cells as we previously reported (Chou et al., 2011). We further purified the starting cells by sorting the CD34-CD36+CD45+ cell population, in order to exclude possible HSPC (CD34+) contamination. The sorted cells were infected by a single retroviral vector expressing the standard 4 iPS factors. Instead of putting cells under a culture condition of iPS cell induction, the infected erythroblasts at day 2 post transduction were cultured under conditions favoring HSPC growth that include SCF, TPO and FLT3 ligand. In the absence of feeder cells, we observed a transient population of CD34+CD45+ cells characteristic of human HSPCs. Similar to the culture of primary CD34+ HSPCs, these induced CD34+CD45+ cells could not be sustained for more than 3 weeks: resulting cells are either CD34-CD45+ cells in suspension or CD34+CD45- adherent cells. In the presence of stromal cells, however, we observed the proliferation of CD34+CD45+ cells from day 14 post-infection that continued for at least 8 weeks. The standard methylcellulose colony-forming assays confirmed the CD34+CD45+ cells can form both myeloid and erythroid colonies (1% and 0.2%, respectively). The conversion from human CD34-CD36+ committed erythroblasts to CD34+ HSPCs within 2-3 weeks required the iPS reprogramming vector; a GFP control vector is insufficient. Our finding suggests that human committed blood cells can be reprogrammed back to multipotent and expandable blood progenitors, without the need of iPS cell derivation and expansion. We are currently testing the potential of the directly reprogrammed and expanded CD34+CD45+ cells to lymphoid lineages and to engraft in mouse models. We are also examining if we can achieve the same result by using non-integrating vectors and adult MNCs as we did previously for iPS cell derivation (Chou et al., 2011). If successful, our approach provides an alternative method to expand patient-specific HSPCs ex vivo for research and for future clinical transplantation.

W-1156

A ROLE FOR STROMA-DERIVED OSTEOPONTIN IN HEMATOPOIETIC STEM CELL AGING

Novella Guidi[1], Karin Doerr[1], Maria Carolina Florian[1], Hartmut Geiger[2]

[1]Dermatology and Allergic diseases, Ulm University, Ulm, Germany, [2]Experimental Hematology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States

Hematopoietic stem cells (HSCs) are located within bone marrow (BM) in a specific microenvironment referred to as the stem cell niche. HSCs as well as more differentiated hematopoietic cells interact in the BM with non-hematopoietic cells (CD45- cells) called stroma cells. The interaction of stroma cells with HSCs is central to hematopoiesis for regulating cell proliferation, self-renewal, differentiation and location. This interaction is supposed to be regulated by cytokines as well as signalling mechanisms that are at least in part initiated by cell-to-cell interactions. Aging of HSCs is linked to a decreased immune response, an increase in myeloid disease and a reduced regenerative capacity. It is supposed to be driven by primarily stem cell intrinsic mechanisms, and only more recently also stem cell extrinsic mechanisms of HSC aging are being discovered. We thus hypothesized that HSC niches age, and that these aging-associated changes impair HSCs function.
Flow cytometric analyses of BM stroma cells located at the endosteum from either young (2 month) or old C57BL/6 mice (22 month) demonstrated a significant decrease in the frequency of CD45- cells and of the osteoblastic subpopulation CD45-CD44+ in aged mice. Osteopontin (OPN) is a secreted glycoprotein expressed by osteoblasts located close to the endosteum. It regulates the HSC pool size by regulating HSCs quiescence. Further investigating a role of OPN in aging, a significant decrease in expression (by real time PCR) and secretion (by ELISA assay) of OPN in aged stroma was detected, with a significant decrease of the frequency of CD45-OPN+ stroma cells in aged mice. We next tested whether the decrease of OPN in stroma upon aging might be causatively linked to aging of HSCs. In vitro trans-well co-culture experiments of young and old hematopoietic stem and progenitor cells (HSPCs) on young, old and OPN KO stroma cells demonstrated a reduction of the number of LSK cells (Lin-Sca1+c-kit+) after 2 days in the presence of old and OPN KO endosteal stroma cells compared to cells co-cultured on young stroma. Heterochronic transplants of young and old BM cells into young, old and OPN KO mice revealed that an aged environment supports aging-associated lineage skewing of HSCs (myeloid over lymphoid), a decrease in overall engraftment and an increase in the frequency of long term HSCs (LT-HSCs). OPN KO recipients, similarly to aged recipients, also presented with a significant decrease in stem cell engraftment but an increase of the frequency of LT-HSCs, implying a causal role for reduced OPN in aged stroma for regulating aging-associated phenotypes of HSCs. We re-

cently reported that the majority of young HSCs is polar for planar cell polarity proteins and tubulin as well as for acetylated HistoneH4 at Lysine16 within the nucleus (AcH4K16), while the majority of aged HSCs is apolar. Finally we thus investigated the polarity status of LT-HSCs from each of the experimental group of the heterochronic transplants by single cell immunofluorescence staining. Interestingly young and thus polar LT-HSCs, when transplanted into either aged or OPN KO mice turned apolar for tubulin and AcH4K16, while young HSCs transplanted in young mice remained polar. Therefore, aging-associated reduction in OPN expression in stroma implies a novel and critical role for HSCs aging.

THE ROLE OF ACTIVATED LEUKOCYTE CELL ADHESION MOLECULE (ALCAM / CD166) IN HEMATOPOIESIS AND HEMATOPOIETIC STEM CELL NICHE

Brahmananda Reddy Chitteti, Michihiro Kobayashi, Yinghua Cheng, Peirong Hu, Bradley Poteat, Hal E. Broxmeyer, Louis M. Pelus, Melissa A. Kacena, Edward F. Srour
Indiana University School of Medicine, Indianapolis, IN, United States

Hematopoietic stem cell (HSC) fate is controlled by ligand-counter ligand interactions that are expressed independently on HSC and hematopoietic niche (HN) elements. To date, not a single surface marker has been identified as a common marker expressed on murine and human HSC and on cells of the HN. We previously demonstrated that CD166 expression tracks the maturational status of osteoblasts (OB) and promotes higher hematopoietic enhancing activity (HEA). In co-culture studies, hematopoietic potential of HSC declined precipitously with increasing maturational status of OB concomitant with loss of CD166 expression. Fractionation of OB with lineage, Sca1, osteopontin (OPN), CD166, CD44, and CD90 revealed that OB with high Runx2, low osteocalcin expression, and with Lin-Sca1-OPN+CD166+CD44+CD90+ phenotype maintain higher in vitro and in vivo HEA compared to CD166- counterparts. Given that CD166 can mediate homophilic cell-cell interactions, we investigated the role of CD166 in identifying HSC and the impact of CD166 on hematopoiesis, HSC engraftment, and the HN. Interestingly, CD166+, but not CD166- fractions of murine and human repopulating HSC identified by a rigorous hierarchical classification for each species mediated robust long-term engraftment. In the murine system, Lineage- Sca1+ ckit+ (LSK) CD48-CD150+CD166+ cells mediated significantly higher chimerism 4 months post-transplantation (PT) compared to LSKCD48-CD150+CD166- cells suggesting that CD166 identifies long-term repopulating cells beyond what is possible with SLAM markers. Similarly, in the human system, cord blood-derived Lin-CD34+CD38-CD49f-CD166+ cells and Lin-CD34+CD38-CD49f+CD166+ cells engrafted 16 weeks PT in conditioned NSG mice significantly higher than Lin-CD34+CD38-CD49f+CD166- cells demonstrating that the CD166+ but not the CD166- fraction of CD34+Lin-CD38- cells contains long-term engrafting human HSC. In CD166 knockout (KO) mice, numbers of LSKCD48-CD150+ cells in the marrow and Lin-CD48- cells in circulation were significantly reduced relative to wild-type (WT) controls. LSK cells from CD166-/- mice failed to engraft in lethally irradiated WT recipients. Short-term repopulating cells engrafted efficiently in KO mice 1mo PT, but declined substantially thereafter demonstrating that the CD166-/- HN cannot support long-term repopulating cells. We assessed the impact of homophilic CD166 interactions on the HEA of OB using a co-culture system and demonstrated that high HEA was detected when both OB and LSK cells expressed CD166. Reconstitution kinetics data and survival of KO mice under hematopoietic stress conditions suggested that CD166-/- HSC have an intrinsic self-renewal capacity precluding them from both rapid proliferation and expansion and maintenance of the stem cell pool in the HN. Since Stat3 has 3 binding sites on the CD166 promoter, we examined the relationship between expression of Stat3 and CD166. Pharmacologic inhibition of Stat3 expression led to a simultaneous inhibition of CD166 expression. Overall, our data illustrate that CD166 is a universal marker of both murine and human HSC and OB within the HN and suggest that CD166 may modulate HSC-niche interactions and impact stem cell fate. The conserved homology between murine and human CD166 provides an excellent bridge between human and murine studies for efficient translational investigations and interventions for enhancing stem cell engraftment and clinical utility.

W-1158

DEVELOPMENT AND CHARACTERISATION OF A DYNAMIC EX VIVO BONE MARROW (BM) NICHE

Kathryn Futrega[1], Bill Lott[2], Kerry Atkinson[2], Michael R. Doran[1]
[1]Translational Research Institute (TRI), Brisbane, Australia, [2]Institute of Health and Biomedical Innovation (IHBI), Brisbane, Australia

Background: Ex vivo hematopoietic stem cell (HSC) niche recapitulation and HSC self-renewal remain among the holy grails of stem cells biology. Despite decades of laboratory and clinical research, the expansion of human HSC, capable of contributing to long-term engraftment in transplant recipients, has not been achieved. At present, the most promising HSC culturing techniques are cytokine/growth factor-supplemented liquid suspension cultures and 2-dimensional (2D) monolayer co-cultures. Co-cultures are intended to mimic the multicellular HSC niche environment, but their 2D geometry does not effectively mimic native cellular organization and ultimately this compromises the quality of the mimic. Our group has developed the first high-throughput, scaffold-free 3-dimensional (3D) HSC co-culture system. We use an in-house fabricated microwell surface to assemble hundreds-to-thousands of multicellular microaggregates, each containing 100 bone marrow (BM) derived mesenchymal stromal cells (MSC) and 10 human umbilical cord blood (UCB)-derived CD34+ cells - we term these mimics "micromarrows". Herein, we contrast the capacity of this 3D niche mimic to expand/maintain umbilical cord blood-derived CD34+CD38- cells relative to conventional 2D co-cultures.
Methods: The microwell surface was fabricated from polydimethylsiloxane (PDMS) and modified with an electrostatic multilayer to prevent cellular adhesion to the PDMS surface. The micromarrows were assembled with a ratio of 100 MSC to 10 CD34+ cells. Control 2D co-cultures were performed in parallel by seeding the same number of MSC and CD34+ cells in fibronectin-coated wells. Co-cultures were maintained for 7 days in a 2% O2, 5% CO2 atmosphere in serum-free X-Vivo 15 medium (Lonza), supplemented with a minimal amount of cytokine (10 ng/ml SCF). Furthermore, we tested the effect of growth factors that act indirectly, via MSC, on hematopoietic cells in 2D and 3D co-cultures and determined the number of CD34+CD38- cells. Cultures were characterized using fluorescence flow cytometry and confocal microscopy.
Results: Our results indicate that the scaffold-free 3D co-culture system supports the expansion of UBC-derived CD34+ cells and exhibits significantly more expansion of the CD34+CD38- cell population, compared to 2D co-cultures. During the first 3 hours of 3D co-culture, spontaneous cell aggregation occurs with hematopoietic cells organizing within the bulk MSC microsphere. Over the subsequent culturing period, the bulk MSC aggregate continues to condense, while hematopoietic cells 'spill' out of the microsphere as they migrate and/or proliferate, forming a proximal expanding cell pool. The addition of certain growth factors that act on MSC to co-cultures resulted in comparable CD34+ expansion in both 2D and 3D co-cultures; however, the CD34+CD38- population was depleted at a much lower MSC density in 2D compared to 3D.
Conclusion: Preliminary results suggest that 3D co-culture is a promising expansion platform for HSCs and may be a promising platform for BM niche recapitulation. The indirect effect of HSC differentiation factors is ameliorated in 3D co-cultures, suggesting this co-culture platform may be suitable for preserving more primitive HSC populations over long culturing periods. Moreover, this culturing system may serve as a tool to study complex HSC-MSC interactions ex vivo, such as those that drive HSC quiescence, proliferation, differentiation, migration and apoptosis.

W-1161

HETEROGENEITY OF YOUNG AND AGED MURINE HEMATOPOIETIC STEM CELLS REVEALED BY QUANTITATIVE CLONAL ANALYSIS USING CELLULAR BARCODING

Evgenia Verovskaya, Mathilde Broekhuis, Erik Zwart, Martha Ritsema, Ronald van Os, Gerald de Haan, Leonid Bystrykh
European Research Institute for the Biology of Ageing, University Medical Centre Groningen, Groningen, Netherlands

The number of hematopoietic stem cells (HSCs) that simultaneously contribute to blood formation, and dynamics of their clonal contribution is a matter of on-going discussion for the last five decades. Recent discoveries of heterogeneity of differentiation, migration and cycling behavior within the HSC pool further complicate this question. It is unclear how different HSC behaviors co-manifest within the same animal, what the number of active HSCs at a mo-

ment of time is and what the dynamics of polyclonal hematopoiesis upon aging is. Here we utilized combination of cellular barcoding technique and multiplex deep sequencing detection for high-resolution, quantitative, sensitive analysis of clonal fluctuations in hematopoietic system. Using this system, we studied clonal behavior of hundreds of young and old hematopoietic clones in mono-, oligo- and polyclonally repopulated mice and addressed different levels of HSC heterogeneity. Blood analysis showed that the majority of transplanted clones stably contributes to hematopoiesis over time, however clonal output in granulocytes, T cells and B cells is substantially different. While the clonal repertoire remained consistent from 12 up to 54 weeks post-transplant, contributions of the clones were dynamically changing, most of the clones either growing or declining in time. We further analyzed the population of primitive cells in the bone marrow and observed that HSC clones were mosaically distributed throughout the skeleton of the mice. Comparison of old and young HSCs revealed that the pool of old HSCs is composed of multiple small clones while young HSC pool can be dominated by a few clones. These data supports the theory of clonal stability of hematopoiesis, and at the same time demonstrate that this process is dynamic. We confirm that cellular barcoding analysis is instrumental in addressing multiple levels of heterogeneity in clonal HSC behavior in polyclonal system.

THE FRIZZLED DOMAIN FROM COLLAGEN XVIII (FZC18) CONTROLS HEMATOPOIESIS AND MYELOIDOGENESIS IN MICE

Valerio Izzi, David Vicente, Inderjeet Kaur, Raman Devarajan, Heli Ruotsalainen, Mari Aikio, Hanne-Kaisa Honkanen, Ritva Heljasvaara, Taina Pihlajaniemi
Center for Cell-Matrix Research and Biocenter Oulu, University of Oulu, Oulu, Finland

Collagen XVIII (Col18), characterized by the antiangiogenic/tumor-suppressive endostatin domain at its C-terminus, occurs as three N-terminal variants. The corresponding gene has two promoters, promoter 1 encoding the shortest variant and promoter 2 the middle and longest variants. The longest variant is characterized by a frizzled-like domain (FZC18), known to be shed from full-length Col18, and shown to act as a soluble inhibitor of the Wnt3a/beta-catenin pathway. In view of the known importance of Wnt3a in hematopoietic stem cell (HSCs) development and myeloidogenesis, and the fact that Col18 is expressed in the bone marrow, we decided to investigate the effects of lack of Col18 on mouse hematopoiesis.
Using total and promoter-specific knockout mice for Col18, as well as mice overexpressing FZC18 under the keratin 14 (K14) promoter, the whole hierarchy of HSCs was screened for alterations in the numbers of self-renewable HSCs (srHSCs), multipotent precursors, myeloid and lymphoid precursors and mature bone marrow myeloid cells. The same mouse cohorts were also screened for differences in blood and spleen leukocyte counts and for embryonic HSCs at different developmental stages. Furthermore, in vitro long-term bone marrow cultures and myeloid cells cultures were adopted to clarify the role of FZC18 domain in hematopoiesis and myeloidogenesis.
Our data show for the first time a role for Col18 in hematopoiesis, as witnessed by a significant increase in HSCs in the knockout mice, both in the whole bone marrow as well as at specific stages during embryonic development. This effect was found to be more pronounced in promoter 2 knockout mice, recoverable in vitro with purified FZC18 protein, and totally absent in knockout mice overexpressing FZC18. As a consequence of HSCs impairment, a significant hematopoietic reprogramming towards myeloid progenitors was observed, which resulted in a wide increase of monocyte and granulocyte counts in the blood accompanied by a marked decrease in immature myeloid cells (IMCs) within the bone marrow.
Altogether, specific ablation of the middle and longest Col18 variants leads to an increase in srHSCs which reflects on peripheral monocyte and granulocyte accumulation, without any appreciable effect on the specific compartment of the immune response. These data thus provide evidence of novel roles for Col18 and its FZC18 variant, capable of binding Wnt molecules, as endogenous controllers of myeloidogenic commitment during HSC development.

W-1163

AUTOLOGOUS UMBILICAL CORD BLOOD FOR REGENERATIVE MEDICINE APPLICATIONS

Katherine S. Brown[1], Heather L. Brown[1], David T. Harris[2]

[1]Scientific and Medical Affairs, Cbr Systems, Inc., San Bruno, CA, United States, [2]Department of Immunobiology, University of Arizona, Tucson, AZ, United States

Background:
For over 20 years, umbilical cord blood (UCB) has been a source of hematopoietic stem cells (HSCs) for use in transplant medicine to treat malignancies, blood disorders and genetic diseases. Newborn stem cells are now being researched in regenerative medicine applications to repair damaged or diseased tissues outside of the blood and immune system. Preclinical studies have shown that UCB contains a heterogeneous population of stem cells. Furthermore, cord blood stem cells have been shown to migrate to injured tissues, secrete therapeutic factors and modulate the immune system. These findings suggests that UCB stem cells may have potential for a variety of regenerative medicine applications. Autologous cell sources, such as family banked UCB, are preferred in regenerative medicine, as they do not have immune complications nor require conditioning regiments.
Objective:
To assess the indications and characteristics of UCB units released by a family stem cell bank for autologous use in regenerative medicine.
Methods:
UCB was collected from consenting mothers who elected to family bank. The UCB was transported to Cord Blood Registry (CBR)'s processing facility in Tucson, AZ. The whole blood product was processed to remove the plasma and majority of the red blood cells and other non-engrafting cells. The processed UCB was stored in the vapor-phase of liquid nitrogen in dewars at -195C until requested for use. Prior to release of the unit, viability and percent CD34+ (or CFU) were assessed from an attached segment by the treating institution. Viability assays varied by institution. Infusions were performed under research protocols at major medical institutions.
Results:
Through January 30th of 2013, CBR released 236 UCB units. 72 (30.5%) units were released for use in a transplant while 164 (69.5%) units were released for autologous regenerative medicine therapies including: cerebral palsy (90), traumatic brain injury (4), autism (4), type 1 diabetes (11) and other conditions. 31 units used for regenerative medicine were released for patients participating in clinical trials. The mean storage time for autologous units was 36.12 months, the mean viability was 95.1% and the mean CD34+ cell count was 0.52%.
Conclusion:
UCB is increasingly being utilized as a source of stem cells in cellular therapies for treatment of a wide range of disorders. Clinical trials are evaluating the safety and efficacy of UCB in regenerative medicine applications such as cerebral palsy, traumatic brain injury, autism and pediatric stroke. The data here support that emerging therapies utilizing autologous cord blood stem cells are a significant and growing percentage of all the treatments facilitated by a family bank. Family banks provide a valuable resource for storing UCB for future autologous or related allogeneic stem-cell based therapies and are facilitating a new era of clinical research focused on regenerative medicine.

A SUB-POPULATION OF EXPANDED HEMATOPOIETIC PROGENITOR CELLS THAT RETAIN HIGH ALDEHYDE DEHYDROGENASE ACTIVITY DEMONSTRATE ISLET REGENERATIVE PROPERTIES

Ayesh K. Seneviratne[1], Gillian I. Bell[2], David M. Putman[1], David A. Hess[1]

[1]Physiology and Pharmacology, University of Western Ontario, London, ON, Canada, [2]Robarts Research Institute, London, ON, Canada

357 million individuals worldwide currently have diabetes and >90% of these patients will develop severe vascular complications shortening their life expectancy. We have previously identified that human umbilical cord blood (UCB) cells with high aldehyde dehydrogenase activity ($ALDH^{hi}$), a conserved stem cell function of multiple progenitor lineages, can stimulate β-cell proliferation and islet vascularization after intrapancreatic transplantation into mice with steptozotocin (STZ)-induced diabetes. However, UCB $ALDH^{hi}$ cell are rare (<0.5% of MNC), and expan-

sion of these cells under clinically applicable regimens will be required to treat patients with diabetes. Interestingly, $ALDH^{hi}$ stem cells are primarily composed of hematopoietic progenitor cells (HPC, 93.3 ± 1.9% $CD45^{+}$, N=3) that are efficiently expanded in short-term culture. Thus, the purpose of these studies was to characterize the islet regenerative capacity of UCB-derived $ALDH^{hi}$ cells after clinically applicable serum-free expansion under hematopoietic conditions *ex vivo.* We hypothesized that culture-expanded HPC that retain high-ALDH activity would stimulate islet regeneration via paracrine mechanisms after transplantation *in vivo*. $ALDH^{hi}$ cells were first isolated from human UCB (n=8) using fluorescence activated cell sorting (FACS), and expanded in serum-free media supplemented with hematopoietic cytokines (10ng/mL rhSCF, rhFLT3L, rhTPO). Using these conditions total cell number was increased by 18.6±2.6 fold within 6 days, and 1 in 8 expanded progeny possessed multipotent hematopoietic colony forming capacity in methylcellulose media (n=4). Interestingly, a distinct sub-population (13.2±2.7%) of expanded progeny retained high ALDH-activity characteristic of hematopoietic progenitor cells ($ALDH^{hi}$-HPC). $ALDH^{hi}$-HPC also expressed primitive myeloid (99.9±0.1% $CD33^{+}$) and hematopoietic progenitor cell markers (77.6±4.2% $CD34^{+}$, 48.2±7.7% $CD133^{+}$) without the acquisition of mature monocyte (0.4±0.1% $CD14^{+}$) or macrophage markers (0.6±0.2% $CD11b^{+}$). Next, 6-day expanded HPC bulk progeny were intravenously (iv)-transplanted into STZ-treated NOD/SCID mice, and blood glucose levels were monitored to evaluate hyperglycemia reduction *in vivo*. Surprisingly, mice transplanted with expanded bulk HPC (n=9) remained severely hyperglycemic, similar to PBS-injected controls (n=6). Therefore, expanded HPC progeny were re-selected for low versus high ALDH activity ($ALDH^{lo}$-HPC vs $ALDH^{hi}$-HPC), prior to iv-transplantation. Remarkably, mice transplanted with $ALDH^{hi}$-HPC (n=5) demonstrated reduced systemic glucose levels and improved glucose tolerance, compared to mice transplanted with $ALDH^{lo}$-HPC (n=6). Although immunohistochemical characterization of the islet regenerative programs stimulated by these cells is ongoing, these preliminary finding suggest that expanded HPC that retain high ALDH activity possess robust islet regenerative capacity *in vivo*. This data identify expanded $ALDH^{hi}$-HPC as a novel cell population for clinical application, and provide strong justification for the further development of expansion, re-selection, and transplantation technologies using UCB-derived HPC for islet regenerative therapies in patients with diabetes.

NFI GENES ARE NOVEL REGULATORS OF HEMATOPOIETIC- AND PROGENITOR CELL REPOPULATING POTENTIAL

Per Holmfeldt, Jennifer Pardieck, Shannon McKinney-Freeman
St. Jude Children's Research Hospital, Memphis, TN, United States

Hematopoietic stem cells (HSCs) are both necessary and sufficient to sustain the complete blood system of vertebrates. HSCs are heavily utilized in the clinic for bone marrow transplants (BMTs) to treat a variety of diseases. However, a lack of suitable donors and inefficiency in recipient engraftment currently limit this life saving therapy. To improve BMT regimens, a better understanding of regulators of HSC BM engraftment is required.
The transcription factor Nfix, a member of the nuclear factor I (Nfi) family of transcription factors, is highly expressed in HSCs. This fact suggests that Nfix may play a novel role in regulating HSC function. To test this hypothesis, HSCs were enriched from adult BM (Lineage-, c-kit+, Sca-1+ (LSK) cells) and then transduced with lentiviruses carrying shRNAs targeting Nfix. Twenty-four hours post-transduction, cells were injected into lethally irradiated mice along with untransduced BM LSK competitor cells congenic at the CD45 allele. The peripheral blood of recipient mice was then analyzed periodically over 16 weeks for engraftment of the Nfix-depleted cells. Depletion of Nfix by two independent shRNA (confirmed by Western blot analysis to deplete Nfix protein levels to <20% of baseline) resulted in a significant decrease in the repopulating activity of BM LSK cells relative to LSK cells transduced with either of two independent control shRNAs. As early as two weeks post-transplant, a 22% +/- 5% ($p=0.03$) reduction in repopulating activity was observed. By 16 weeks post-transplant, this reduction in repopulating potential had gradually increased to 55% +/-8% ($p<0.0001$) in four independent experiments. Lineage analysis of peripheral blood of recipients showed no significant differences in the distribution of the major blood lineages derived from LSK cells transduced with Nfix- specific shRNAs compared to controls. Depletion of either Nfia or Nfic, two Nfi family members also expressed by HSCs, in LSK cells via shRNAs led to a similar loss in LSK repopulating potential, sug-

gesting a general role for Nfi genes in the regulation of hematopoietic stem and progenitor repopulating potential. When the BM of recipients transplanted with Nfix- depleted LSK cells was examined 4 and 16 weeks post-transplant, a loss of phenotypic HSCs (LSK/CD150+/CD48-) relative to controls was evident. Thus, the observed decrease in repopulating activity likely occurs at the level of HSCs and multipotent progenitors
Analysis of early engraftment revealed that Nfix-depleted LSK cells established in the BM but failed to expand due to excessive apoptotic cell death. Critically, in vitro analysis of BM LSK expansion in liquid culture revealed no differences in the activity of LSK cells transduced with Nfix-specific shRNAs compared to controls. Thus, it is unlikely that the observed decrease in BM repopulating activity is due to general cytotoxicity resulting from Nfix-depletion. Moreover, gene expression profiling revealed that a number of previously described HSC regulators, Evi1, Mpl and Prdm16, were downregulated in Nfix-depleted LSK cells. Current studies aim to elucidate if any of these genes has a direct causative role for the observed phenotype following Nfix depletion and whether they are direct transcriptional targets of Nfix.
In summary, we have for the first time established a role for the Nfi gene family in HSC biology, as evident by a decrease in BM repopulating activity in HSCs depleted for the expression of these genes.

TARGETED INHIBITION OF INNATE IMMUNOSURVEILLANCE TO PROMOTE THE ENGRAFTMENT OF HEMATOPOIETIC STEM CELLS

Nathaniel B. Fernhoff, Irving L. Weissman
Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA, United States

Despite the enormous therapeutic potential of bone marrow transplants, the procedure carries significant risks of morbidity and mortality. Some of the risks are associated with the cytoreductive conditioning regimen that clinicians must use to clear niche space and promote donor cell engraftment. Without high-dose radiation or chemotherapy, donor bone marrow cells fail to engraft in host bone marrow. Other risks are associated with transplanting donor T cells, which cause an immune response against host tissue. However, depleting T cells from transplants causes a further increase in engraftment failure. Therefore, there is a pressing medical need to develop new methods to increase donor cell engraftment in bone marrow transplants. We are developing a novel strategy of therapeutic delivery that may find wide application in transplant biology. CD47 is a ubiquitously expressed “don’t eat me signal” that negative regulates macrophage activation and phagocytosis. Cell surface CD47 expression is a necessary factor for hematopoietic stem cell engraftment in wild-type mice and a sufficient factor to promote the engraftment of MOLM-13 cell line in immunodeficient mice. Because of the risks associated with gene therapy, we are capitalizing on protein-based strategies to artificially increase CD47 protein levels on the donor cell surface. Using biotin / streptavidin crosslinking, we have successfully increased cell surface display of CD47 and we are actively characterizing the effect on bone marrow transplants and hematopoietic stem cell transplants with various conditioning regimens. We propose to treat donor bone marrow cells ex vivo with both of these strategies in order to evade innate immunosurveillance and promote donor cell engraftment.

ENDOTHELIAL BLOOD BONE MARROW BARRIER REGULATES NORMAL AND LEUKEMIC STEM AND PROGENITOR CELL TRAFFICKING AND MAINTENANCE

Tomer Itkin[1], Shiri Gur-Cohen[1], Aya Ludin[1], Karin Golan[1], Alexander Kalinkovich[1], Orit Kollet[1], Ralf H. Adams[2], Tsvee Lapidot[1]
[1]Immunology, Weizmann Institute of Science, Rechovot, Israel, [2]Department of Tissue Morphogenesis, Max Planck Institute for Molecular Biomedicine, Münster, Germany

Bone marrow (BM) endothelial cells (BMEC) serve as ‘niche’ cells

for both hematopoietic and mesenchymal stem and progenitor cells (HSPC/MSPC). Yet, BMEC-mediated synchronization of HSPC bi-directional trafficking through the blood-bone marrow-barrier (BBMB) and of stem cell maintenance is poorly understood.
In vivo treatment with the angiogenic cytokine FGF-2 resulted in increased BM HSPC/MSPC numbers and repopulation potential, while reducing peripheral blood (PB) HSPC numbers and their repopulation potential from the PB. FGF-2 treated mice had reduced BBMB permeability evaluated by dye penetration and incorporation, and reduced HSPC BM homing. We have generated endothelial specific inducible FGF receptor knock-out (eFGFR1/2 KO), using VE-Cadherin-CRE^{ERT2} and FGFR1$^{flx/flx}$/FGFR2$^{flx/flx}$ transgenic mice). Importantly, eFGFR1/2 KO mice exhibited reduced BM stem cell levels. FGF-2 treatment was able to increase stem cell levels only in WT BM, but not in the BM of eFGFR1/2 KO mice. FGF-2 treated eFGFR1/2 KO mice failed to exhibit increased HSPC retention and reduced BM homing like in WT treated mice. These results suggest that endothelial specific activation of FGF signaling regulates the BBMB control of HSPC bi-directional trafficking. Thus, hampering endothelial FGF signaling interferes with stem cell maintenance and expansion, while increasing BBMB permeability. In addition we have observed that Nestin-GFP MSPC co-localize with non-permeable blood vessels. Mechanistically, FGF-2 treatment resulted in decreased BM MMP-9 activity combined with upregulated Timp-1 (MMP-9 inhibitor) mRNA levels. Furthermore, FGF-2 treatment activated AKT, and reduced NO and ROS content in BMEC. Importantly, permeability regulating endothelial junction molecules such as VE-Cadherin and ZO-1 were upregulated following FGF-2 treatment. Administration of neutralizing VE-Cadherin antibodies efficiently increased HSPC egress by increasing BBMB permeability. These results suggest that interfering with endothelial adhesion interactions alone increases HSPC trafficking. Examination of eNOS KO and Timp-1 KO mice revealed that HSPC bi-directional trafficking was decreased in eNOS KO mice and increased in Timp-1 KO mice. In the BM, primitive, repopulating HSPC numbers were increased in eNOS KO mice and decreased in Timp-1 KO mice. Of interest, we observed that chimeric immune-deficient mice transplanted with malignant human pre-B ALL cells, exhibited reduction in BBMB permeability. We suggest that leukemic cells stimulate BMEC in order to support their own maintenance, expansion and chemoresistance via reducing BBMB permeability, and CXCL12 while increasing SCF levels. This suggests that human leukemias can modify the BBMB to a malignant-supportive microenvironment and that BBMB targeting could hamper leukemia expansion and protection, to improve clinical chemotherapeutic protocols.
In conclusion, our findings reveal that normal and malignant stem cell migration and development are dynamically regulated by BMEC. We suggest that BMEC balance their dual roles as stem cell niches, and as an anatomical barrier synchronizing HSPC bi-directional trafficking. Thus, unbalanced BBMB function towards either stem cell trafficking or maintenance will come at the expense of the other.

DEVELOPMENT OF AN OPTIMAL CULTURE SYSTEM FOR INDUCTION OF FUNCTIONAL HUMAN NEUTROPHILS FROM SERUM-FREE EXPANDED HEMATOPOIETIC STEM CELLS

Chao-Ling Yao, Yu-Shuo Hu
Department of Chemical Engineering and Materials Science, Yuan Ze University, Chung-Li City, Taiwan

Hematopoietic stem cells (HSCs) from bone marrow, peripheral blood and cord blood are widely used in transplantation after cancer chemotherapy. Among them, there are several limitations of cord blood hematopoietic stem cell transplantation, such as slow recoveries of neutrophils and platelets. The aim of this study is to develop an optimal neutrophil induction culture system to increase the number of neutrophils in vitro, to accelerate the recovery of patient's autoimmune system after cord blood HSC transplantation and to overcome the limitation of clinical application.
In this study, HSCs were isolated from cord blood and were expand by a serum-free HSC expansion system (SF-HSC medium) that was developed previously by our lab. Then we screened five of cytokines (SCF, G-CSF, GM-SCF, IL-3 and IL-1) and optimized the concentration of cytokines that can effectively induce serum-free expanded HSCs into CD66+/MPO+ cells. In addition, we also checked CD66+/MPO+ cells by neutrophil-associated surface antigens, such as CD11b, CD13, CD15, CD16, CD33, CD64, TLR2 and TLR4, and neutrophil-specific functional assays, such as

phagocytosis assay, chemotaxis assay and cellular ROS production assay. Finally, we confirmed induced cells were functional neutrophils.
In this study, we have successfully established a neutrophil induction medium that can effectively induce HSCs into mature and functional neutrophils in vitro. We believe that combination of SF-HSC medium and neutrophil induction medium can generate a large amount of functional neutrophils and provide a promising cell source for basic research and clinical application in the future.

DYNAMICS OF LONG-TERM HSPC SUBTYPES IN NON-HUMAN PRIMATES REVEALED BY A DECADE-LONG CLONAL TRACKING EXPERIMENT

Sanggu Kim[1], Namshin Kim[2], Angela P. Presson[1], Mark E. Metzger[3], Gay M. Crooks[1], Dong-Sung An[1], Robert E. Donahue[3]

[1]University of California, Los Angeles, Los Angeles, CA, United States, [2]Korean Bioinformatics Center, Daejeon, Korea, Republic of, [3]National Heart, Lung and Blood Institute, Bethesda, MD, United States

Hematopoietic stem cell and progenitor cell (HSPC)-based genetic therapy to treat HIV or other previously incurable diseases is becoming increasingly realistic. The composition of the primate HSPC pool nor the regenerative potential of cells composing the HSPC pool is, however, yet to be clearly understood due partly to the lack of appropriate in vivo models and experimental tools. Here, we report detailed behavior patterns of repopulating HSPCs in four rhesus macaques transplanted with autologous CD34+ cells 4 to 12 years ago after myeloablative conditioning. Prior to transplantation, cells were transduced with either control lentivirus vectors expressing EGFP or vectors expressing both EGFP and shRNA against the HIV-1 co-receptor, C-C chemokine receptor type 5 (CCR5). All animals showed normal hematopoietic recovery and maintained stable marking in all tested blood lineages. In order to study the behavior of engrafted HSPCs, vector marked clones in serially collected blood as well as different blood lineages were analyzed using a high-throughput quantification assay. The assay, involving large-scale vector integration site (VIS) sequencing and bioinformatics analysis of VIS sequences, allowed sensitive quantification of individual clones in a polyclonal blood cell pool. Unlike traditionally used techniques that employed bulk populations, our clonal marking tracked the functional behavior of a single cell. Analysis revealed thousands of HSPC clones expanded sequentially over time in each animal, clustered into groups with different kinetics of repopulation, maintaining the total marked blood cells at a relatively stable level over the years. While short-term repopulating clones provided rapid and transient immune recovery, long-term engrafted clones gradually expanded and became the main source of repopulating cells starting from 8 - 13 months post-transplantation. Importantly, consistent with recent discoveries in murine HSC studies, these long-term clones were also distinctively grouped into “myeloid-biased”, “lymphoid-biased”, and “balanced” subtypes based on their unique lineage output potentials. Clones with more balanced lineage potentials, accounted for only 4 − 10% of the identified clones, yet predominated, contributing up to 25 − 71 % of total repopulating cells in each animal. No notable effect of CCR5 shRNA expression upon clonal repopulation was observed. Our long-term clonal tracking revealed new insights regarding the biology of primate HSPCs, providing a potential frame of reference for future HSPC based gene therapy clinical trials.

HIERARCHICAL CHANGES OF HUMAN HEMATOPOIETIC STEM CELL DIFFERENTIATION DURING ONTOGENY

Sasan Zandi, Faiyaz Notta, Stephanie Dobson, Naoya Takayama, John E. Dick
UHN, Toronto, ON, Canada

Hematopoietic stem cells (HSCs) undergo phenotypic, functional, and anatomic changes over the course of ontogeny. Murine studies show differences in surface markers, cytokine dependency and self-renewal/differentiation capacity of stem and progenitors between the fetus and adult. The system tends to produce more lymphoid and megakaryocytic-erythroid (Mk/E) cells in fetal stage but changes in favor of more myeloid biased outputs in adults. During aging, this myeloid (My) bias correlates with increased incidence of myeloid malignancies such as acute myeloid leukemia (AML). Our understanding of the dynamics of human hematopoiesis during ontogeny is very limited due to the absence, until recently, of consistent methods to clonally resolve human HSC and progenitors. Using these advanced sorting methods and a highly efficient single cell functional assay that supports My, E and Mk differentiation, we traced the lineage potential of nearly 4000 deposited single cells from highly purified HSC and progressively restricted progenitor populations from across human development. There was a progressive reduction in the proportion of HSC and multipotent progenitor cells between fetal liver to adulthood. Strikingly in the adult, all multipotent cells are relegated to the CD34+CD38- stem cell compartment. Although CMP are commonly considered as CD34+CD38+, our single cell analysis of adult BM showed that more than 95% the cells in CD34+CD38+ compartment are unipotent, revealing important developmental changes. We then used CD71 (transferrin) and cMPL (TpoR) to identify new classes of hematopoietic progenitors in human FL, cord blood (CB) and adult BM. While >90% of CD34+CD38+CD71+cMPL+ cells in adult BM are committed erythroid progenitors, in FL and CB more than 40% of them are multipotent. Noticeably Mk cells can be generated from several different multipotent progenitors indicating multiple branching points for Mk in FL and CB. In-vivo repopulation assays in NSG mice confirmed that CD71 and cMpl expression marks erythroid-committed progenitors with varying degrees of proliferation capacity that can be resolved based on variation in CD45RA and Flt3 expression. To gain further insight into molecular mechanisms governing early commitment of erythroid and megakaryocyte lineage, we used Fluidigm to quantify the expression of lineage-associated genes in single progenitors that expressed a combination of these surface markers. We detected co-expression of EpoR, TpoR and GATA1 in more than 90% of CD71+cMpl+ progenitors from FL, while >85% of adult BM CMPs expressed Mpo and GCSFR but lacked erythroid associated genes. Our gene expression data also showed that stemness programs extend much farther down into the hierarchy within the fetal stage where progenitors are more flexible to adopt E, Mk or My fates. It is only in the adult BM stage that progenitors make binary and distinct decisions.

HUMAN HEMATOPIETIC STEM AND PROGENITOR CELLS INJECTED IN HUMANIZED NSG AND MITRG MICE ENGRAFT THE MENINGEAL COMPARTMENT

Mariangela Amenduni[1], Anthony Rongvaux[2], Richard A. Flavell[2], Flora M. Vaccarino[1]
[1]Child Study Center, Yale University, New Haven, CT, United States, [2]Department of Immunobiology, Yale School of Medicine, New Haven, CT, United States

Microglia, the resident macrophages of the CNS, are thought to participate in the pathogenesis of neurodevelopmental and neurodegenerative diseases. However the origin of brain microglia remains unclear. It has been recently shown that in mice microglia derive from primitive myeloid progenitors of the yolk sac and that these cells are able to penetrate the developing brain around embryonic day 8. On the contrary perinatal circulating hematopoietic precursors do not seem to significantly contribute to the pool of adult microglia.
This result is in contrast with previous studies showing that bone -marrow derived cells able to engraft the brain during neurodegeneration and inflammation and differentiate into microglia-like cells when bone marrow transplantation is preceded by irradiation-mediated immune ablation. To date there is no evidence that this is true also in humans. We tested whether human hematopoietic stem and progenitor cells (HSPCs; CD34+ cells isolated from human fetal liver) are able to differentiate into brain microglia. Our data indicate that HSPC transplanted in the liver of neonatal immunodeficient mice expressing multiple human cytokines required for myelopoiesis (M-CSF, GM-CSF, IL-3 and TPO) are not able to engraft the adult mouse brain; indeed, human cells positive for CD11b/Iba1 are mainly localized within the meninges. To address whether the blood brain barrier that is already formed after birth might have prevented human hematopoietic cells from entering the brain, we injected the HSPCs in embryonic mouse brain at E12; however, engrafted human cells positive for CD11b/Iba1 were localized in the meninges. Future research will reveal whether HSC are already committed toward a more differentiated state and/or lack brain specific- triggers that allow these cells to colonize the brain. Furthermore it would be interesting to understand whether

these cells are able to enter the brain after damage and whether they will display the same characteristics of the endogenous yolk sac-born microglia.
Knowing the unique origin of microglial cells will in fact contribute to better understand their role in neurological and psychiatric disorders and develop therapeutic strategies, since specific myeloid cells-from the yolk sac, bone marrow or blood could each be involved in shaping circuit development and pruning. These cells could also used to deliver specific compounds into the damaged brain.

INCREASED MIR-223 EXPRESSION DYSREGULATES MYELOID DIFFERENTIATION IN PTPN11-ASSOCIATED JMML

Sonia Mulero-Navarro[1], Ana Sevilla[1], Angel Roman[2], Dung-Fang Lee[1], Sunita D'Souza[1], Jie Su[1], Christoph Schaniel[1], Brian Brown[1], Hélène Cavé[3], Marco Tartaglia[4], Ihor Lemischka[1], Bruce Gelb[1]
[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States, [2]Instituto Cajal-Consejo Superior de Investigaciones Científicas, Madrid, Spain, [3]Department of Genetics, AP-HP-Robert Debré Hospital, and Paris-Diderot University, Paris, France, [4]Dipartimento di Ematologia, Oncologia e Medicina Molecolare, Istituto Superiore di Sanità, Rome, Italy

Somatic
mutations in *PTPN11*, encoding the
RAS/MAPK regulator SHP-2, cause juvenile myelomonocytic leukemia (JMML). Germ-line *PTPN11* defects cause Noonan syndrome
(NS), while specific inherited mutations cause NS/JMML. Hematopoietic cells differentiated from human induced pluripotent stem
cells (hiPSCs) harboring NS/JMML-causing *PTPN11*
mutations recapitulated JMML features including granulocyte macrophage
colony-stimulating factor hypersensitivity and increased fetal hemoglobin,
documenting sufficiency of the *PTPN11*
mutation for leukemogenesis. hiPSC-derived NS/JMML myeloid cells exhibited increased signaling
through STAT5 and up-regulation of miR-223 and miR-15a.
Reducing miR-223's function in NS/JMML hiPSCs normalized myelogenesis.
Micro-RNA target gene expression levels were reduced in hiPSC-derived myeloid
cells as well as in JMML bone marrow mononuclear cells, of which ~70%
of the patient samples also showed miR-223 and/or miR-15a up-regulation. The findings confirm the utility of studying
inherited human cancer syndromes with hiPSCs to understand early oncogenesis
prior to the accumulation of secondary genomic alterations and provide opportunities
for therapeutic target discovery and small molecule testing.

W-1175

THE ARYL HYDROCARBON RECEPTOR (AHR) REGULATES THE PRODUCTION OF BIPOTENTIAL HEMATOPOIETIC PROGENITOR CELLS

Brenden W. Smith[1], Sarah S. Rozelle[1], Amy Leung[1], Shirley K. Nah[1], Deborah French[2], Paul Gadue[2], Darrell N. Kotton[1], Gustavo Mostoslavsky[1], David H. Sherr[3], **George J. Murphy**[1]
[1]Boston University Center for Regenerative Medicine (CReM), Boston Univ School of Medicine, Boston, MA, United States, [2]Center for Cellular and Molecular Therapeutics, Children's Hospital of Philadelphia, Philadelphia, PA, United States, [3]Dept. of Environmental Health, Boston Univ School of Public Health, Boston, MA, United States

The evolutionarily conserved aryl hydrocarbon receptor (AhR), a member of the basic helix-loop-helix Per-ARNT-Sim family, has been studied for its role in environmental chemical-induced toxicity. Recent studies now demonstrate that the AhR may regulate the hematopoietic and immune systems during development in a cell-specific manner. To better understand the possible role of the AhR in hematopoiesis, we developed a novel, human, induced pluripotent stem cell (iPSC) platform based on the step-wise directed differentiation of hematopoietic progenitor cells. Our in silico analysis of transcriptional profiles of 71 primary human hematopoietic cell isolates indicated AhR-upregulation at both the hematopoietic stem cell and bi-potential megakaryocyte-erythroid progenitor (MEP) stages. This result, together with the absence of an in vitro model system enabling production of large numbers of primary human MEPs capable of differentiating into megakaryocytes (Mks) and erythroid lineage cells, motivated us to determine if AhR modulation could facilitate both MEP expansion and Mk and erythroid cell differentiation.

Our results indicate that AhR has a physiological and functional role in normal hematopoietic development, and that modulation of the receptor in bi-potential hematopoietic progenitors can direct cell fate. We demonstrate a novel methodology for the directed differentiation of pluripotent stem cells in chemically defined, serum and feeder-free culture conditions into MEPs capable of final specification into Mks and/or erythroid-lineage cells. The use of a non-toxic aryl hydrocarbon receptor agonist in our directed differentiation scheme significantly increases the number of MEPs and resultant cells. Following the addition of potent AhR ligands to our cultures, we observed exponential expansion of MEPs from fifteen thousand to one billion cells in two weeks, with the role of AhR in the MEP population confirmed using a specific AhR inhibitor. This logarithmic expansion of cells appears to be a function of decreased cell death and is consistent with previous studies which suggest that the AhR can control apoptosis. In addition to allowing for the exponential expansion of MEPs, our results demonstrate that modulation of AhR can direct cell fate, with AhR agonism permissive to erythroid differentiation and antagonism favoring Mk specification. Although erythropoietin (EPO) and thrombopoietin (TPO) stimulate RBC and Mk production respectively, AhR may play a cytokine-independent role in the specification of these lineages and warrants further study.

These results demonstrate a new platform for studying human red blood cell and MK development that allows for exponentially greater production of RBCs and Mks in comparison to existing methodologies. This strategy relies on the first of its kind definition of the role of the AhR receptor in normal hematopoietic development using specialized ligands in hematopoietic progenitor cells. A useful outcome for this work will be the utilization of this in vitro platform for the clinically relevant production of blood products. An iPSC-based system, such as the one described here in which sufficient numbers of cells can be produced, should facilitate future clinical adaptation involving the transfusion of iPSC-derived red blood cells and platelets without problems related to immunogenicity, contamination, or supply.

IN VIVO TIME LAPSE IMAGING OF MOUSE BONE MARROW REVEALS DIFFERENTIAL NICHE ENGAGEMENT BY QUIESCENT AND PHYSIOLOGICALLY ACTIVATED HAEMATOPOIETIC STEM CELLS

Mark Scott[1], Narges Rashidi[1], Jens Kalchscmidt[1], Nico Scherf[2], Ingo Roeder[2], Kleoniki Gounaris[1], Murray Selkirk[1], **Cristina Lo Celso**[1]

[1]Life Sciences, Imperial College London, London, United Kingdom, [2]Institute for Medical Informatics and Biometry, Technical University Dresden, Dresden, Germany

Understanding the mechanisms linking stem cell-niche interaction and stem cell fate is critical for developing regenerative medicine approaches. The nature of such interactions between hematopoietic stem cells (HSC) and the bone marrow (BM) microenvironment has long been elusive due to the difficulty of penetrating bones for direct observation and the fluid nature of the hematopoietic tissue itself. Several functional studies based on ablating or overexpressing specific genes in the hematopoietic or distinct BM stroma compartments have highlighted the presence of an intricate and dynamic network of regulatory signals responsible for the crosstalk between HSC and the BM microenvironment. The question, however, remains open as to whether multiple, molecularly and functionally

distinct HSC niches exist within the bone marrow and whether HSC trafficking between them may be necessary to switch fate between quiescence and proliferation, self-renewal and differentiation.
To address this question, we developed an imaging technique combining two photon and confocal microscopy that allows in-vivo imaging of live transplanted hematopoietic stem and progenitor cells (HSPC) in mouse BM with single cell resolution. Using this technique we showed that engrafting long-term repopulating HSC (LT-HSC) localize near osteoblastic cells, while their progeny are more distal. Our results also highlight that localization of LT-HSC and their progeny near osteoblasts correlates with improved engraftment outcomes. Studies based on single time-point observations demonstrated that asynchronous HSPC proliferation initiates BM reconstitution, however did not provide information about long-term interactions between HSC and their BM niche (or niches), which are responsible for maintenance of balanced hematopoiesis. We therefore developed a new in vivo imaging experimental protocol, allowing time-lapse imaging of HSPC, leading us to uncover their differential abilities to engage with the BM microenvironment over time. Moreover, using a physiological model of HSC activation, we observed that changes in the nature of the interactions between stem cells and the BM microenvironment accompany switches in fate choice.

A COMPARISION OF INTRAUTERINE HAEMOPOIETIC STEM CELL & DIRECT IN VIVO LENTIVIRAL THERAPIES FOR BETA THALASSEMIA MAJOR IN A MURINE MODEL OF FETAL THERAPY.

Niraja Dighe[1], Lay Geok Tan[1], Daren Sandikin[1], Simon Waddington[2], Michael Antoniou[3], Mahesh Choolani[1], Jerry Chan[1], Citra Mattar[1]

[1]Experimental Fetal Medicine Group, Department of Obstetrics and Gynecology,, National University of Singapore, Singapore, Singapore, [2]Gene Transfer Technology Group,, Institute for Women's Health, University College London,, London, United Kingdom, [3]Department of Medical and Molecular Genetics,, King's College London School of Medicine, Guys Hospital,, London, United Kingdom

AimsSevere haemoglobinopathies like the major thalassaemias cause perinatal complications including death, or chronic illness requiring life-long red cell transfusion. Prenatal stem cell transplantation has not succeeded in correcting the outcomes of these diseases thus far. Yet fetal therapy could possibly arrest pathogenesis early enough to allow perinatal survival, or to improve the severity of the disease such that transfusion independence is acquired. To realize the putative benefits of the fetal microenvironment that may facilitate genetic correction, we investigated the dual intrauterine strategies of haemopoietic stem cell transplantation (IUHSCT) and direct in vivo gene therapy (IUGT) designed to treat a murine fetal model of beta thalassaemia major. Our specific aims were to compare donor cell engraftment, vector biodistribution and phenotype improvement in treated progeny.
MethodsHbb/Th3+ males were backcrossed with C57BL/6 females on a CD45.2 background. IUHSCT fetuses were given $2x10^5$-$1x10^6$ cells of either murine fetal liver-derived CD45.1 mononuclear cells, or human fetal liver-derived HSCs intraperitoneally. Cells were treated with Diprotein A for CD26 inhibition just prior to transplantation. In the IUGT arm, F1 fetuses were given $5x10^6$ TU IV (via the vitelline vein) of a lentiviral vector (LV) LCR-β-globin. Injections were performed at E15-18. Weaned pups were analysed by genotype, blood smears and haematological indices. Chimerism was determined in peripheral blood in IUHSCT pups, and was studied in the liver, bone marrow and spleen at six months. IUGT pups were monitored by vector biodistribution and intracellular expression of human beta globin. Phenotype changes were studied in treated Hbbth3/+ offspring, while uninjected progeny served as controls.
Results In the IUHSCT arm, peripheral blood chimerism was observed at a median level of 0.54% (n=8, range 0.1-1.7%) with murine CD45.1 cells, while with human CD45 cells median engraftment was 0.33% (n=20, range 0.1-3.4%) at 8 weeks. Median levels of engraftment in bone marrow, liver and spleen (n=17) were 0.17% (range 0.1-0.54%), 1.05% (range 0.1-5.96%) and 0.16% (range 0.1-0.95%) respectively at 6 months. DNA chimerism was confirmed by qPCR. At this level of microchimerism, there was no difference in haematological parameters between untreated and injected Hbbth3/+ progeny.

In contrast to cell therapy, haematological indices in Hbbth3/+ recipients showed marked improvement with lentiviral treatment over controls from 4 to 20 postnatal weeks (n=2). Red cell counts increased to 8.3+/-1.2 E+6/µl (vs. 5.2+/-0.2E+6/µl, $p<0.05$) and haemoglobin levels improved to 12+/-1.4g/dL (vs. 9.6+/-0.3g/dL, $p<0.05$). Despite this, blood smears showed
persistent evidence of haemolysis. Vector copy number in peripheral blood ranged from 0.2-4.6 (median 2.4 copies per cell).
ConclusionIUHSCT at current cell doses resulted in microchimerism with no significant haematological improvement. In contrast, lentiviral IUGT showed greater efficacy in treating Hbbth3/+ mice, although we observed only partial albeit significant correction. Despite this initial success, the long-term effects of LV use must be determined as there are numerous safety concerns. As the safety profile of IUHSCT is likely to be more favourable, we are currently studying various strategies to improve engraftment, including postnatal cell boosting.

W-1181

IMMUNOSUPRESSION MEDIATED BY HUMAN ADIPOSE DERIVED MSC INVOLVES A CELL CONTACT-DEPENDENT MECHANISM.

Suzdaltseva Yulia, Goryunov Kirill, Rubtsov Yuri, Tkachuk Vsevolod
Moscow State University, Moscow, Russian Federation

Human adipose-derived mesenchymal stem cells (hASCs) are the candidate cellular therapeutics in regenerative medicine. Extensive research has focused upon the MSC-dependent immunomodulate properties. Various molecular mechanisms can be involved in hASC-mediated immune suppression. These mechanisms underlying hASCs-mediated immunosupression include soluble factors and cell-cell contacts, which possibly depend on expression of cell adhesion molecules. In the present study the potential mechanism involved in regulatory cell induction by allogenic hASCs was examined. To dissect cell contact-dependent mechanism of hASC-dependent immune suppression in vitro co-culture system consisting of hASCs and phytohemaglutinin-activated peripheral blood lymphocytes (PBL) was established. hASCs isolated from adipose tissue were characterized for human MSC surface marker expression and differentiation potential. hASCs inhibited proliferation of activated PBL both in trans-well and cell-contact coculture system as assessed by CyQuant cell proliferation assay. hASC-conditioned growth medium had no effect on proliferation of activated PBL. Activation of lymphocytes with hASCs had also resulted in increased attachment of immune cells to hASCs. Flow cytometry analysis of bound CD4+ and CD8+ T cells, NK and B cells with fluorophore-conjugated antibodies against surface markers reveals that activated CD4+ T cells are capable to bind hASCs more effectively in comparison to non-activated. At the same time, the capability of other analyzed immune cells to bind hASCs decreased or did not change. The protein and mRNA levels of ICAM increased in both activated T-cells and hASCs in contact cocultures compared with cells cultured alone or separately in transwells. We showed that hASCs-dependent suppression of activated T-cell proliferation is not associated with reduction of IL-2R (CD25) expression or apoptosis. hASCs were shown to induce FoxP3 mRNA and protein expression in CD4+ T-cells. This effect required direct contact between hASCs and CD4+T-cells. On the other hand hASCs stimulation with activated lymphocytes induces indoleamine-2,3-dioxygenase (IDO) synthesis. The increased level of IDO mRNA was observed in hASCs co-cultured with activated PBMC in cell-cell contact system in comparison to separate cocultures. It addition, through use of antagonist and neutralizing antibodies, IDO were shown to correlate with induction CD4+CD25+FoxP3+ T-cells in cell-cell contact coculture. Taken together our data support the substantial role of cell contact-dependent mechanism in hASC-mediated immune suppression.

SOMATIC PROGENITOR CELL HOMEOSTASIS IS DISRUPTED BY MITOCHONDRIAL DNA MUTAGENESIS IN PREMATURELY AGING MICE.

Kati J. Ahlqvist[1], Riikka H. Hämäläinen[1], Kirmo Wartiovaara[2], Tomas Prolla[3], Anu Suomalainen[1]

[A]Research Programs Unit, Molecular Neurology, [1]University of Helsinki, Helsinki, Finland, [2]Department of Genetics, University of Wisconsin, Madison, WI, United States

Mitochondria produce energy in form of ATP to be used in all cellular functions. Mitochondria have its own circular DNA encoding for 13 polypeptides, tRNAs and rRNAs. All the proteins encoded by the mitochondrial DNA (mtDNA) are subunits of respiratory chain complexes I, III, IV and V. ATP is synthesized by respiratory chain (RC), which also produces superoxide as a by-product, so RC defect may, besides decreasing ATP production, increase the production of reactive oxygen species (ROS). When mtDNA is mutated, it often leads to RC dysfunction, which in turn leads to ineffective energy production and/or increased ROS production.
Somatic stem cell (SSC) dysfunction is typical for different progeroid phenotypes in mice with genomic DNA repair defects. Increased mtDNA mutagenesis can also result in progeroid phenotype in mice. “Mutator” mice show extensive mtDNA mutagenesis because of an inactivated exonuclease function of the mitochondrial replicative DNA polymerase gamma (POLG). Their phenotype mimics premature aging, starting from 6-8 months of age, with progressive hair graying, alopecia, osteoporosis and general wasting. Their life span is limited to 13-15 months because of severe anemia, with age-dependent decline in erythro- and lymphopoiesis, recently suggested to be due to HSC dysfunction. POLG forms the minimal mtDNA replisome together with the mitochondrial single-stranded DNA binding protein and a replicative helicase, Twinkle. If dominant mutant Twinkle is overexpressed in mice, large-scale mtDNA deletions accumulate in postmitotic tissues (hence the “Deletor” mice), leading to progressive late-onset mitochondrial myopathy at 12 months of age and RC deficient neurons, but normal life span. We asked whether SSC dysfunction could contribute to the mtDNA mutagenesis-linked premature aging, and utilized the two mouse models with mtDNA maintenance defects, Mutator and Deletor, of which only the former showed a premature aging phenotype.
We found that Polg-Mutator mice had neural (NSC) and hematopoietic progenitor (HPC) dysfunction already from embryogenesis. NSCs extracted from E12 embryos showed accumulation of mtDNA point mutations and the self-renewal ability of NSCs was decreased in vitro. Also the amount of quiescent NSCs in adult brain was reduced in vivo.
Mutator fetal liver showed changes in erythropoiesis already before the onset of anemia. FACS analysis of fetal liver HPCs showed decreased amount of basophilic erythroblasts (CD71+,Ter119+), whereas the amount of more mature erythroblasts (Ter119+,CD71low) was increased. Mutator fetal liver HPCs produced more erythroid colonies compared to wild type cells when cultured in methylcellulose. N-acetyl-L-cysteine treatment rescued both NSC and HPC abnormalities during embryonal development, suggesting that subtle ROS/redox changes, induced by mtDNA mutagenesis, modulate SSC function. We also found delayed maturation of erythrocytes in adult Mutator peripheral blood, including ineffective clearance of transferrin receptor and organelles, and long-term NAC-treatment is ongoing.
Our results show that mtDNA mutagenesis affected SSC function early but manifested as respiratory chain deficiency in nondividing tissues in old age. Deletor mice, having mtDNA deletions only in postmitotic cells and no progeria, had normal SSCs. We propose that SSC compartment is sensitive to mtDNA mutagenesis, and that mitochondrial dysfunction in SSCs can underlie progeroid manifestations.

RECRUITMENT OF HEMATOPOIETIC STEM AND PROGENITOR CELLS IS REGULATED BY THE ANGIOGENIC FACTOR EPIDERMAL GROWTH FACTOR-LIKE DOMAIN 7

Ismael Gritli, Chiemi Nishida, Aki Sato, Shinya Munakata, Hiroshi Shimazu, Yoshihiko Tashiro, Kaori Kusubata, Hiromitsu Nakauchi, Koichi Hattori, Beate Heissig
The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Epidermal growth factor-like domain protein 7 (Egfl7), known to play a role in angiogenesis, is expressed during embryogenesis, in hematopoietic stem cells (HSCs) as well as in certain myeloid leukemias. The contribution of Egfl7 to hematopoiesis has not yet been described. Herein, we studied the effects of forced expression of Egfl7 on murine hematopoiesis. Enforced expression of Egfl7 resulted in a marked enhanced myeloid and megakaryocytic cell

differentiation *in vivo*. Overexpression of Egfl7 expanded the number of hematopoietic stem and progenitor cells (HSPC) in the BM of non-myelosuppressed mice. In addition, adenoviral-mediated overexpression of Egfl7 into non-myelosuppressed mice caused mobilization of immature progenitors into circulation. Using a hematopoietic stress model, *Egfl7* was upregulated in BM cells upon Fluorouracil (5-FU)-induced injury. Overexpression of Egfl7 using an adenoviral delivery system resulted in accelerated hematopoietic recovery, especially of myeloid cells and platelets after 5-FU treatment, accompanied by a dramatic increase in HSPC within the BM. Overexpression of Egfl7 in mice accelerated the entrance of HSCs into cell cycle and myeloid (granulocytic) and megakaryocytic differentiation after myelosuppression. Kit-ligand, SDF-1α, and VEGF-A were identified as novel downstream target molecules after Egfl7-forced expression.
These data suggest that increased expression of Egfl7, as found after myelosuppression within BM cells or released from endothelial cells of a growing tumor, can promote myeloid cell proliferation and differentiation, and cause HSPC mobilization, most likely due to its ability to alter the secretion pattern of critical stem cell niche factors (Kit-ligand, SDF-1α and VEGF-A).

COMPREHENSIVE ANALYSIS OF HEMATOPOIETIC STEM CELL NICHE

Aparna Venkatraman, Xi C. He, Ariel Paulsonl, Hua Li, Linheng Li, Ryohichi Sugimura Sugimura
Stowers institute for medical research, Kansas city, MO, United States

Bone marrow niches and the signals emanating from them are critical for maintaining quiescent and active hematopoietic stem cells (HSC). Though a variety of stromal cells are reported to be HSC niche components, the integration of molecular signals emanating from different niche component to maintain different states of HSC is largely unclear. Combining high throughput RNA sequencing with protein expression analysis, we provide a comprehensive view of the unique and combinatorial ability of several niche components to maintain various HSC states. The reporter mice used were Nestin+, Cspg4+, Sdf+(mesenchymal stromal cells), Col2.3+(mature osteoblasts, mOB),Col3.6+, N-Cadherin+ (pre-osteoblast, pOB) and Pecam+(endothelial cells). Megakaryocytes, macrophages and HSCs were separated using surface markers. Analysis of major signaling pathways in stem cell function revealed at least three distinct zones.
The Endosteal zone- This zone mainly comprises of mOBs (Col2.3+) and pOBs (N-Cadherin+). Our data revealed that the two types of cells are quite distinct. Genes involved in maintenance of HSC quiescence including Opn, Cxcl12 and Angpt2 were preferentially expressed in N-cadherin+ pOBs. Members of BMP signaling like BMP4 known to play key role in stem cell quiescence were preferentially expressed in N-Cadherin+ pOBs. Analysis of Wnt signaling revealed members of non-canonical Wnt signaling and inhibitors of canonical Wnt signaling were predominantly expressed in N cadherin+ cells. Cytokines were minimally expressed in this zone. Cell adhesion molecules of cadherin family- Cdh2, 11; Integrin family- Itga 7, 8 and 11 were uniquely expressed in N cadherin+ cells.
The Perivascular zone- This mainly comprised of stromal cells around the arteriole and included Nestin+ and Cspg4+cells. Unique expression in Nestin+ included BMP signaling antagonist Noggin and Lif , members of both canonical and non-canonical Wnt signaling. Unlike the endosteal zone, expression of canonical Wnt signaling inhibitors was negligible. Cytokines and cell adhesion molecules were less abundant in this zone.
The Sinusoidal zone- This comprised of Pecam+ cells and megakaryocytes since sinusoids and these differentiated hematopoietic cells are present scattered throughout the central bone marrow. Ligands of Notch signaling, including Jag1, 2, and Dll4 were uniquely expressed in Pecam+ stromal cells. Jagged 1, involved in retention of HSC in the undifferentiated state, was also expressed in N-Cadherin+ pOBs. SCF as ligand for cKit were preferentially expressed in Pecam+ stromal cells. Cell adhesion molecules of the integrin family and members of Fgf signaling involved in HSC proliferation, homing and mobilization were preferentially expressed in this zone.
In summary, our data indicates that N-cadherin+ cells present in the endosteal zone have the highest expression of genes involved in stem cell quiescence. In contrast, suppressed BMP signaling, and presence of canonical and non-canonical signaling members in Nestin+ cell in peri-vascular zone suggested HSCs in this zone are in a binary state of quiescence and active. High expression of Scf, Fgfs, and Notch ligands in Pecam+ cells and megakaryocytes suggest that the sinusoidal zone support proliferation and mobilization of stem cells. Hence this comprehensive analysis in

gene and protein reveal that different niche components play unique as well as co-operative roles for maintenance and regulation of different states of HSCs.

DELETION OF NOTCH1 TRANSCRIPTIONAL ACTIVATION DOMAIN REVEALS A NOVEL ROLE FOR NOTCH1 SIGNALING IN FETAL HEMATOPOIETIC STEM CELLS

Kostandin V. Pajcini[1], Dawson Gerhardt[1], Teresa D'Altri[4], Lanwei Xu[1], Olga Shestova[2], Jonathan Epstein[3], Nancy Speck[3], Anna Bigas[4], Warren S. Pear[1]

[A]Pathology and Laboratory Medicine, [B]AFCRI Cancer Institute, [C]Cell and Developmental Biology, [1]University of Pennsylvania, Philadelphia, PA, United States, [2]Cancer Research Program, IMIM-Hospital del Mar, Barcelona, Spain

Notch1 contains a conserved transcriptional activation domain (TAD) that is required for optimal signaling in vitro and for Notch1-induced T-ALL. To determine its developmental function, knock-in mice lacking the Notch1 TAD (ΔTAD/ΔTAD) were generated. Unlike Notch1 knockouts, ΔTAD/ΔTAD mice survive until late gestation, succumbing to multiple cardiac abnormalities. Notch1 is required to generate the earliest embryonic hematopoietic stem cells (HSC); however since Notch1-null embryos die early in gestation, additional functions for Notch in embryonic HSC biology have not been described. Notch1 TAD deficient HSCs successfully transit to the E11.5 fetal liver, but are decreased in frequency compared to wild type and are defective in competitive bone marrow transplant experiments, a phenotype recapitulated in RBPJf/f conditional knockout mice. Loss of Notch1 TAD impairs Notch1 core complex formation on the Hes1 promoter and consequently inhibits Hes1 expression. Together, these studies reveal an essential role for the Notch1 TAD in embryonic development and identify important cell autonomous functions for Notch1 signaling in fetal HSC homeostasis.

W-1186

HUMAN FETAL BONE MARROW MESENCHYMAL STEM CELL DERIVED FROM SECOND-TRIMESTER FETUS DEMONSTRATE A STRONGER HEMATOPOIETIC SUPPORTIVE CAPACITY THAN FETAL LIVER MESENCHYMAL STEM CELL

Xiao Hu[1], Yongjuan Duan[1], Fang Li[2], Yi Sun[1], Chunmin Fang[1], Xiaoting Wang[1]

[1]Institute of Hematology, The Chinese Academy of Medical Sciences, Tianjin, China, [2]Shandong University, Jinan, China

Mesenchymal stem cells, which play a major role in establishing hematopoietic microenvironment, have been isolated from various tissues in the early developing embryo and the adult organism. During ontogeny, hematopoietic stem cells (HSC) shift from fetal liver and spleen to adult bone marrow and this movement may be due to favorable inductive signals from different microenvironments. It is of great interest for both basic research and translational application to understand the nature of the hematopoietic microenvironment. A few *in vitro* study has demonstrated that fetal bone marrow MSC(FBM-MSC), compared with adult bone marrow MSC(ABM-MSC), is less perfect for adult HSC maintenance and differentiation. However, similar evidence is lacked for the fetal HSC in fetal liver MSC (FL-MSC) and fetal bone marrow MSC (FBM-MSC) which represents the fetal hematopoiesis. This study was aimed to compare the hematopoietic supportive capacity for fetal HSC and adult HSC between fetal liver and fetal bone marrow MSC *in vitro*.

Fetal liver MSC (FL-MSC) and fetal bone marrow MSC (FBM-MSC) of the same fetus were isolated from three second trimester fetuses between gestations of 16 to 25 weeks. Another six fetal liver MSCs were isolated from gestation stage matched and unmatched fetuses. After irradiation, MSC were co-cultured with CD34(+) cells isolated from umbilical cord blood (UCB-CD34+)or fetal liver (FL-CD34+). The total nucleated cell number were counted and the phenotypic changes of co-cultured CD34(+) cells were analyzed by flow cytometry and the colony forming unit cells were analyzed by CFU forming assay. UCB-CD34+cells were drive into erythroid differentiation by cytokine

cocktail then co-cultured with FL-MSC or FBM-MSC for terminal maturation and enucleation. Erythroid culture was analyzed by flow cytometry with CD71 and CD235a antibodies and DNA dye LDS751.
The results showed that cell morphology varies between FL-MSCs and FBM-MSCs, yet immunophenotype of CD34, CD45, CD105, CD49e, CD90, CD44 expression are comparable between FL-MSCs and FBM-MSCs. Both types of cells demonstrated similar osteoblastic differentiation capacity, yet FL-MSC has less strong adipogenic differentiation capacity. FBM-MSC had a stronger hematopoietic supportive capacity than FL-MSC for both fetal and adult HSCs, yet the supportive capacity is more prominant for adult HSCs than fetal HSCs. In addition, FBM-MSC has a stronger capacity to promote terminal maturation of UCB-CD34+ erythroid culture. Both of them enhanced the differentiation of CD34(+) cells into myeloid lineages. The study also found that cytokines were expressed differently in FBM-MSC and FL-MSC. The study supports the hypothesis that hematopoietic stem cells move to favorable microenvironment during ontogeny and provides clues to engineer better hematopoietic niches for *in vitro* hematopoietic differentiation.

Endothelial Cells/Hemangioblasts

HIGHLY EFFICIENT AND SCALABLE GENERATION OF FUNCTIONAL ENDOTHELIAL CELLS FROM HUMAN PLURIPOTENT STEM CELLS BY A NOVEL GSK3 INHIBITOR.

Christoph Patsch[1], Eduard Urich[1], Eva Christina Thoma[1], Klaus Christensen[1], Tobias Heckel[1], Lin Sun[2], Xin Jiang[2], Wei He[1], Per-Ola Freskård[1], Paul Huang[3], Dorothee Kling[1], Martin Graf[1], Roberto Iacone[1]
[1]Pharma Research Early Development, Roche, Basel, Switzerland, [2]Harvard Stem Cell Institute, Cambridge, MA, United States, [3]Massachusetts General Hospital and Harvard Medical School, Cardiovascular Research Center and Cardiology Division, Boston, MA, United States

The use of human pluripotent stem cells (PSCs) for *in vitro* disease-modeling and clinical applications is limited by the ability to rapidly produce pure populations of various cell types in sufficient quantities.
Herein, we describe a scalable monolayer protocol to induce vascular cells in chemically defined conditions driven by a novel and potent GSK3ß inhibitor. Within six days we generated large cell populations that are highly enriched for endothelial cells (VE-Cadherin$^+$ ≥85%). We isolated VE-cadherin$^+$ cells by magnetic activated cell sorting (MACS) to ensure pure and homogenous endothelial cell cultures (≥98%). Time-resolved whole-genome expression and selective qRT-PCR analysis revealed a gene expression pattern closely resembling early embryonic vasculogenesis. Further characterizations of VE-Cadherin$^+$ cells, confirm a functional endothelial phenotype. Stem cell-derived endothelial cells give rise to continuous endothelium with dynamic barrier function properties, form vascular network-like structures in angiogenesis assays, show *in vivo* angiogenic potential, convert into activated endothelium after treatment with pro-inflammatory cytokines, thereby facilitating the recruitment of leukocytes. Overall the purified VE-Cadherin$^+$ cells present an endothelial-specific expression pattern; positive for PECAM-1$^+$, CD34$^+$, VE-Cadherin$^+$, vWF$^+$, CXCR4$^+$, VEGFR2$^+$, VEGFR3$^+$ and negative for the hematopoetic lineage markers CD45$^-$, CD43$^-$ and for the smooth muscle cell markers PDGFRβ$^-$, SMA$^-$ The endothelial cell population maintained their cellular identity over the period of cultivation.
This novel and robust method allowed us to reproducibly generated large numbers of homogenous endothelial cells from more than 20 different PSC lines including disease-specific lines from patients that have vascular complication associated with Type 2 Diabetes. With the growing need for defined protocols, our differentiation system may become the standard for deriving endothelial cells at relevant scales appropriate for drug discovery campaigns and regenerative therapies.

W-1192

NEUROPILIN-1 IDENTIFIES THE EMERGENCE OF ENDOTHELIAL COLONY FORMING CELLS FROM HUMAN PLURIPOTENT STEM CELLS

Nutan Prasain[1], Man R. Lee[2], J. Luke Meador[2], Sasidhar Vemula[1], Momoko Yoshimoto[1], Michael J. Ferkowicz[1], Hal E. Broxmeyer[2], Mervin C. Yoder[1]

[A]Pediatrics, [1]Indiana University School of Medicine, Indianapolis, IN, United States

Endothelial colony forming cells (ECFCs) are rare circulating endothelial progenitor cells with robust clonal proliferative potential that display intrinsic *in vivo* vessel forming ability. While ECFCs form durable and functional blood vessels *in vivo*, they are rare in number in peripheral blood and their number tends to decline with age and disease. Thus, harnessing autologous ECFCs derived from patient specific induced pluripotent stem (hiPS) cells may be an innovative alternative approach to repair the damaged blood vessels in patients with peripheral artery disease (PAD) at risk for critical limb ischemia. While directed differentiation of hiPS and human embryonic stem (hES) cells into the endothelial lineage has been reported to generate endothelial cells with a mature endothelial phenotype possessing low proliferative potential, derivation of endothelial cells with ECFC properties (progenitor cells with clonal proliferative potential and *in vivo* vessel forming ability) from human pluripotent stem (hPS) cells (both hiPS and hES cells) has not yet been reported.

In order to identify ECFCs from hPS cells undergoing endothelia lineage differentiation, we utilized previously reported protocols (both mouse stromal OP9 cells and embroid body-induced endothelial differentiation protocols) to differentiate hiPS and hES cells into endothelial lineages and characterized isolated putative endothelial cells for ECFC properties. The putative endothelial cells that were derived from these protocols exhibited low clonal proliferative potential and were highly unstable often transitioning into non-endothelial phenotype and failed to give rise to functional in vivo vessels upon implantation into immunodeficient mice, suggesting that endothelial cells derived from the existing protocols lacked the ECFC properties. Therefore, based upon the known importance of vascular endothelial growth factor (VEGF) signaling pathway in the emergence of endothelial cells during development, we developed a novel endothelial differentiation protocol and found neuropilin-1 (NRP-1), a VEGF co-receptor, as an early marker for identifying the emergence of ECFCs from hPS cells. Endothelial lineage differentiation was initiated by growing hPS cells in endothelial differentiation media supplemented with growth factors for 12 days on Matrigel coated dishes. On day 12, cells were harvested and sorted using antibodies that recognize endothelial antigens CD31, CD144, CD146, and NRP-1. Sorted cells were subsequently cultured in endothelial growth (EGM-2) media. Compared to other sub-sets of sorted cells, only NRP-$1^{+}$$CD31^{+}$ cells exhibited ECFC properties. NRP-$1^{+}$$CD31^{+}$ formed a homogenous monolayer with characteristic cobblestone appearance, exhibited clonal proliferative potential, demonstrated angiogenic behavior by forming capillary like structures when cultured on Matrigel, and formed robust *in vivo* vessels when in implanted in immune deficient mice. Collectively, we conclude that the emergence of ECFCs from hPS cells is identified by the endothelial subset expressing NRP-1. Overall, these studies would provide new information on a potentially critical factor and mechanism that control specification and emergence of endothelial cells with ECFC properties from hiPS cells, thereby, provide an innovative strategy to produce large numbers of autologous *in vivo* vessel forming cells to restore deficient microvasculature in patients with cardiovascular disease.

W-1193

A SYSTEMATIC APPROACH TO ELUCIDATING THE OPTIMAL CONDITIONS FOR EFFECTIVE HARVEST OF ENDOTHELIAL OUTGROWTH CELLS

Dedy Sandikin[1], **Mark Chong**[2], Mahesh A. Choolani[1], Jerry K Y Chan[3]

[A]Obstetrics and Gynaecology, [1]National Univ of Singapore, Singapore, Singapore, [2]Reproductive Medicine, KK Women's and Children's Hospital, Singapore, Singapore

Endothelial Progenitor Cells (EPC) from circulating blood have been the subject of intense research for diagnostic and therapeutic applications. In particular, Endothelial Outgrowth Cells (EOC), an EPC subset, demonstrate lineage stability and proliferation capacity, leading to their proposed use in tissue engineering and regenerative medicine. However, translation to clinics has been hampered by significant differences in experimental observations across research groups, leading to questions on reproducibility of results and, indeed, on the exact identity of these cells.

We hypothesised culture conditions to influence harvest efficiency of EOC and sought to optimise the protocol for maximal EOC yield from umbilical cord blood (UCB). Following informed consent, term UCB (n=86) were obtained and the influence of mononuclear cell (MNC) separation, seeding density, sera and substrates were systematically evaluated. In spite of a 10-fold reduction in total nucleated cell counts following density centrifugation, EOC could not be generated from direct cultures of whole blood, suggesting the process of red blood cell depletion to be critical. Subsequently, seeding density was studied and established to be inversely related to harvest yield, with a seven-fold increase in number of EOC colonies obtained following a four-fold reduction in seeding density ($p<0.01$). The effects of sera were then studied. Varying serum concentrations from 10 to 50 percent of total culture medium was not found to significantly influence yield. Strikingly, batch-dependence was found to be the major factor, with EOC found to be reliably generated from only two out of seven lots of sera tested from three companies. Finally, substrate coating was not found to influence the number of colonies generated, nor cellular phenotype as assessed by surface marker profile and functionality, as assessed by Matrigel network formation assays. In conclusion, the isolation of EOC from UCB was successfully optimised, with recommendations for red blood depletion, optimal seeding density and batch testing of sera for the reproducible generation of EOC. Identification of sera components that promote or inhibiting colony formation is currently under way.

DOSAGE OF VASCULAR ENDOTHELIAL GROWTH FACTOR REGULATES HEMATOPOIETIC STEM VERSUS PROGENITOR CELL FATE IN HEMOGENIC ENDOTHELIUM

Lydia K. Lee, Masaya Ueno, Luisa Iruela-Arispe, Hanna A. Mikkola
Department of Molecular, Cell and Developmental Biology, University of California, Los Angeles, Los Angeles, CA, United States

Healthy donors comprise the only source of transplantable hematopoietic stem cells (HSC) to date, as their production *in vitro* from pluripotent cells has been unsuccessful. So far, the mechanisms that dictate hemogenic endothelium fate to multipotent, self-renewing HSC rather than transient myeloerythoid progenitors are poorly understood. A critical signaling pathway acting on embryonic mesoderm and endothelium is the Vascular Endothelial Growth Factor A (VEGF-A)/VEGFR2 pathway, a potent regulator of vasculogenesis and angiogenesis. Although its function in embryonic hematopoiesis has been implied, developmental studies using *in vivo* mammalian models are scarce due to the lethality of the *VEGF* heterozygous embryos. To overcome this hurdle and obtain germline heterozygous mutants, we intercrossed female *Vasa-Cre* transgenic mice with $VEGF^{fl/wt}$ males. Remodeling of the yolk sac and embryo vasculature into mature branched networks was severely impaired in haploinsufficient concepti, which never developed beyond E10.5. Surprisingly, although the yolk sac is the site of emergence for the first hematopoietic wave of “primitive” erythroid cells as well as the second wave of “transient-definitive” myeloerythroid restricted progenitor cells, its potential to form either primitive erythroid or myeloerythroid colonies in methylcellulose was unaffected. This finding contrasted prior reports of a major defect in the generation of primitive red blood cells (RBC). FACS analysis and immunofluorescence (IF) confirmed the presence of Ter119+CD71+ βH1-globin primitive RBCs in the yolk sac and the placenta, and suggested that improper vascularization, rather than perturbed hematopoiesis, was the cause for the pale yolk sac.
In contrast, fewer mixed myeloerythroid colonies developed from explants of the placenta and the caudal half of the embryo, which are sites for the final and “long-term definitive” wave generating the multipotent HSCs that differentiate into myeloid, erythroid as well as lymphoid lineages. Moreover, hematopoietic organs from heterozygous embryos could not grow either B or T-lymphoid cells in OP9 and OP9-DL1 stroma co-culture, respectively. Furthermore, IF revealed reduced arterialization in VEGF-A-deficient placenta. These data suggest that proper dosage of VEGF-A is required to develop HSCs and establish arterial identity that is necessary for the specification of hemogenic endothelium to HSC fate.
To define the critical sources of VEGF-A during hematopoiesis, we used complementary tissue-specific genetic models of *VEGF-A* inactivation. Deletion of one *VEGF-A* allele from Tie2-expressing endothelial cells generated mutant embryos that were indistinguishable from their control littermates and robustly generated all types of hematopoietic stem/progenitor cells. Similarly, deletion of one allele of *VEGF-A* from Mesp1-expressing mesodermal cells in

embryonic hemogenic tissues and the heart did not abolish the generation of pRBCs, myeloerythroid progenitors or lymphoid cells. Finally, we deleted one or both *VEGF-A* alleles exclusively from the placental trophoblasts by infecting the trophectoderm with a lentiviral vector encoding Cre. No mutants survived beyond the 26 somite-pair stage, and yolk sac vasculature was poorly remodeled. These data suggest that placental trophoblasts constitute a vital source of VEGF-A during development that may even support hematopoiesis and vasculogenesis in distant hemogenic tissues.

INVESTIGATING THE DIFFERENTIATION OF ARTERIAL AND VENOUS SUBPOPULATIONS OF HUMAN EMBRYONIC STEM CELL DERIVED ENDOTHELIAL CELLS - APPROACH TO VESSEL GENERATION

Edit Gara, Judit Skopál, Annamária Kosztin, Zsolt Bagyura, Tamás Németh, Béla Merkely, Gábor Földes
Heart Center, Semmelweis University, Budapest, Hungary

Human pluripotent stem cell derivatives offer the promise for novel therapeutic possibilities in cardiovascular disease. In this study, we aimed to identify signals responsible for induction of arterial and venous endothelial differentiation. Undifferentiated H7 human embryonic stem cells (hESC) were differentiated into endothelial lineage using monolayer and embryoid-body formation methods. The CD31-positive cells were separated from the differentiating culture by FACS. Human ESC-derived endothelial cells (hESC-ECs) were characterized by their morphological, immunocytochemical and in vitro functional properties. Cells were stained positive for panendothelial markers CD31, von Willebrand factor, and ve-cadherin by immunocytochemistry; cells form capillary-like tubules on Matrigel and can take up acetylated-low density lipoprotein. The role of hypoxia (5% O2) and vascular endothelial growth factor (VEGF) supplementation were assessed on the differentiation of arterial and venous subpopulations. We showed that both hypoxia and VEGF tended to improve the differentiation yield (control, 0.2%; hypoxia, 0.3%; VEGF, 0.7%), however, it stayed low. As assessed by quantitative PCR, culture of hESC-EC abundantly expressed both arterial (EphrinB2, Notch1-2) and venous (EphB4) endothelial markers. The mRNA of lymphatic-specific marker, FLT4 was not detectable. VEGF markedly increased the mRNA levels of arterial endothelial genes as well as venous marker EphB4 in the differentiating culture (Notch1, 18.89±3.75; Notch2, 9.01±2.97; EphrinB2, 11.89±5.29; EphB4, 10.10±3.04-fold increases vs. hESC, all $p<0.01$, n=3). Hypoxia induced higher endothelial marker expressions in monolayer than in EB-derived cultures (Hypoxia-method: Notch1, 6.01±1.68; Notch2, 6.46±1.50; EphrinB2, 2.93±0.68 - fold changes vs hESC all $p<0.05$; EphB4 3.72±1.01 - fold increase vs. hESC; EB-method: Notch1, 1.15±0.60; Notch 2 0.60±0.14; EphrinB2, 0.77±0.13; EphB4, 0.70±0.15 - fold increase vs. hESC,n=3).To test in vivo viability and maturation of the cells, we have transplanted hESC-EC and control HUVEC subcutaneously into athymic nude rats. Immunohystochemistry has proven that hESC-EC form capillary-like structures in vivo. After implantation, the mRNA levels of arterial and angiogenesis markers were significantly higher as compared with preimplanted cells (fold increases, mean±sem: angiopoietin2, 86.23±26.34; apelin, 1197±703, Notch1 440±303; EphrinB2 58±37; n=5, $p<0.05$). Endothelial derivatives of human pluripotent stem cells can be promising future options for tissue engineering in ischaemic cardiovascular diseases and vascular regeneration. VEGF and hypoxia may act as key extracellular signals in the differentiation process toward more specific endothelial subpopulations.

HUMAN ENDOTHELIAL COLONY FORMING CELLS (ECFCS) - IMMUNOGENICITY STUDIES UNDER INFLAMMATORY CONDITIONS AND THE PRESENCE OF MESENCHYMAL STROMAL CELLS (MSCS)

Naima Souidi[1], Katharina Schallmoser[2], Dirk Strunk[2], Caroline Schmidt-Lucke[3], Hans-Dieter Volk[1], Martina Seifert[1]
[1]Immunology, Berlin-Brandenburg Center for Regenerative Therapies / Charité, Berlin, Germany, [2]Hematology/ Stem Cell Transplantation, Medical University of Graz, Graz, Austria, [3]Cardiology/Pneumology, Charité - Universitätsmedizin, Berlin, Germany

Introduction: Endothelial Colony Forming Cells (ECFCs) have been described to have regenerative properties by enhancing endogenous vascular repair processes and forming vascular networks in vitro as well as in vivo. To consider

ECFCs for therapeutic purposes, the cells must be analyzed regarding their immunogenic capacity in an inflammatory environment. Potential therapeutic co-application with Mesenchymal Stromal Cells (MSCs) might not only stabilize vessel formation, but could also promote modulation of ECFC immunogenicity in an inflammatory surrounding.
Methods: We isolated pairs of human umbilical cord derived ECFCs and MSCs from healthy donors and checked for phenotypic and immunogenic marker expression and differentiation capacity. Both cell types were exposed to different pro-inflammatory cytokines for 24h and stained for HLA- and adhesion molecules. Induction of CD4+ T cell-proliferation by ECFCs and MSCs was analyzed using a CFSE-based proliferation assay and measured by multicolor flow cytometry. To assess the potential immunomodulatory cross-talk between both cell types, we additionally performed proliferation assays with mitogen-triggered CFSE-labeled peripheral blood mononuclear cells (PBMCs).
Results: ECFCs and MSCs showed strong constitutive expression of HLA-ABC and ICAM-1. After stimulation with different pro-inflammatory cytokines (TNFα, IL-1β and IFNγ) for 24 hours, both cell types showed enhanced expression of both surface markers. ECFCs triggered with TNFα and IL-1β upregulated the adhesion molecule VCAM-1, whereas MSCs did not respond to IL-1β stimulation. Exposure to IFNγ dose-dependently induced expression of HLA-DR in ECFCs after 24h. In contrast, MSCs remained negative for HLA-DR during the same time frame but showed a delayed upregulation after three days.
The co-culture of IFNγ pre-treated ECFCs with CD4+T cells induced some immune cell proliferation. In contrast, unstimulated as well as IFNγ-treated MSCs failed to trigger proliferation responses. When tested in mitogen-stimulated assays, only MSCs were able to reduce PBMC proliferation significantly. Co-application of ECFCs and MSCs diminished the MSC effects.
Conclusion: ECFCs, in contrast to MSCs, show restricted immunogenicity via the up-regulation of HLA-DR by IFNγ. MSCs were not able to influence the immunogeneic potential of ECFCs. However, ECFCs could reduce the immunomodulatory effects of MSCs.

W-1197

A HIGH-THROUGHPUT SCREENING TO STUDY THE ROLE OF THE HEMANGIOMA-DERIVED STEM CELL (HEMSC) IN TUMOR FORMATION

Shaghayegh Harbi
New York University, New York, NY, United States

Infantile hemangioma (IH) is the most common tumor of infancy. However, little is known of its etiology and pathogenesis of infantile hemangioma. The overall goal of this investigation is to understand the process of hemangiomagenesis – defined as human vascular differentiation, followed by vascular regression and adipogenesis – by characterizing the progenitor hemangioma-derived stem cells (HemSCs). To understand the tumorigenic potential of HemSCs at the single cell level, genetic signatures and cell surface markers need to be identified via a multifaceted and targeted approach, using fluorescence-activated cell sorting (FACS)-purified/enriched **HemSCs** to highlight expression signatures between the progenitor – HemSCs and its derivatives.
Based on the current knowledge of IH biology, we hypothesize that the hemangioma-derived stem cell (HemSC) is a vascular stem/progenitor cell whose proliferation is dysregulated but not fully transformed, that orchestrates hemangioma pathophysiology via sophisticated activation of multiple signaling and regulatory networks.
To explore this hypothesis we propose to develop the following Specific Aims: 1) **To perform a high-throughput FACS analysis of cell surface markers and confirm the results by fluorescence bioimaging:** Through a high throughput screen, characterize human cell surface markers (242-antibody screening) to differentiate between **tumor biomarkers** (diagnostic tool) and **tumor stem cell biomarkers** (therapeutic tool). 2) **To characterize the gene expression profiles and patterns:** Characterize the gene expression profiles and patterns by microarray analysis followed by qRT-PCR and high-throughput analysis using lab-on-a-chip approach with single cell microfluidic analysis (microfluidic based single cell transcriptional analysis and fluorescence-activated cell sorting) of the cultured (FACS sorted) HemSCs and endothelial cells (human umbilical vein endothelial cells, HUVEC); HemSCs and the heterogeneous cell population following exposure to dexamethasone (the steroid commonly used for clinical management

of IH); HemSCs and glioblastoma CD133+ stem cells; HemSCs and Mesenchymal/Bone Marrow/Cord Blood CD133+ stem cells.

Significance Identifying a stem cell (HemSC) as a cellular precursor - with the ability to self renew and give rise to derivative cell types (with a differentiation potential) - two key functional properties of adult stem cells, is paramount in disease intervention and direct drug target therapy of IH as well as in regenerative medicine. Thus further identification and characterization of the HemSCs will lead to practical implications for clinical application. Reaching this goal requires advanced technology for *quantitative characterization of the FACS enriched HemSCs to characterize the cellular biomarkers and the gene expression profiles of the single HemSC.* This approach will provide distinct gene set signatures for diagnostic assays and drug targeting. Understanding the vasculogenic mechanism that controls IH development can also afford understanding the mechanisms that mediate the transformation of certain cancer stem cells into tumor endothelial cells - such as the differentiation of glioblastoma CD133+ cells into endothelial progenitors - potentially indicating a therapeutic target for treating proliferating hemangiomas.

RSK4 SUPPRESSES ENDOTHELIAL CELL FATE THROUGH DIRECT INHIBITION OF PKA ACTIVITY

Taichi Matsunaga[1], Kohei Yamamizu[1], Kazuko Koshiba Takeuchi[2], Mizuyo Kojima[2], Jun K. Takeuchi[2], Jun K. Yamashita[1]

[1]Department of Cell Growth & Differentiation, Center for iPS Cell Research and Application, KYOTO UNIVERSITY, Kyoto, Japan, [2]Division of Cardiovascular Regeneration, Research Center for Epigenetic Disease,, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan

Endothelial cell (EC) differentiation is strictly regulated to generate functional blood vessel. To elucidate the underlying mechanisms of EC differentiation, we have previously established in vitro differentiation system and demonstrated that fetal liver kinase 1 (Flk1) + mesodermal cells derived from ES cells serve as common progenitor of both EC and Mural cells (MC; vascular smooth muscle cells and pericytes). We recently reported that cyclic adenosine monophosphate (cAMP)/protein kinase A (PKA) signaling enhanced EC differentiation from Flk1+ mesodermal cells via induction of VEGF receptors expression. We also revealed that expression of Ets variant2 (Etv2), a key molecule for hemato-endothelial fate, is triggered by PKA signaling. However, little is known about the regulation of PKA signaling in EC differentiation. To further dissect these sequential processes in vascular formation, we investigated a novel molecule target and its function during EC differentiation.

We carried out microarray analyses at various differentiation stages; undifferentiated ES cells, Flk1+ mesodermal cells to ECs and MCs. Then, we found that isoforms of p90 ribosomal S6 protein kinase (RSK) family were specifically expressed in differentiation stages. RSK1 was predominantly expressed in undifferentiated ES cell. RSK2 and RSK3 were highly expressed in EC. RSK4 was expressed in Flk1+ mesodermal cells and diminished in ECs. RSKs are mediators of the Ras/mitogen-activated protein kinase (MAPK) signaling cascade, which controls various biological functions, including cell growth, proliferation and survival. However, the role of RSK family that is still uncharacterized during EC differentiation.

To investigate roles of RSKs in EC differentiation, we examined the effect of a broad-spectrum RSKs inhibitor, SL0101, in our system. SL0101 treatment enhanced VEGF receptor expression and EC differentiation specifically with the simultaneous cAMP signal. SL0101-elicited EC differentiation was abolished by knockdown of PKA catalytic subunit alpha (PKAc), suggesting that the regulation by RSK during EC differentiation is depended on a PKA pathway. To identify RSK isoform that regulates EC differentiation, we investigated EC differentiation using shRNA against each RSK isoform. Among RSK families, RSK1-3, RSK4 knockdown in Flk1+ mesodermal cells similarly showed an increase of EC differentiation via induction of Flk1 and Etv2 expression even in the absence of SL0101. To demonstrate whether RSK4 interacts to PKA, we investigated the mechanisms linking PKA activity to RSK4. The immunoprecipitation and immunoblotting experiments indicated that RSK4 has potential to bind to PKAc. Moreover, RSK4 overexpression significantly decreased PKA activity. Furthermore, to investigate the biological function of RSK4 in vivo, we performed ex vivo whole embryo culture assay. Embryos that were cultured in the presence of SL0101

displayed an aberrant surface of yolk sac. Namely, SL0101 treatment dramatically enlarged the area of CD31+ vasculature in yolk sac.
Taken together, our findings are first evidences of strict system regulated by RSK4 to form correctly vascular development in mouse embryogenesis. RSK4 expression regulates endothelial cell fate through suppression of PKA-mediated Flk1 and Etv2 induction. Elucidation of the new-model cell fate determination by RSK4 would provide novel insights in developmental biology, stem cell biology, and regenerative medicine.

HUMAN UMBILICAL VEIN ENDOTHELIAL CELLS SYNERGIZE OSTEOGENIC/ODONTOGENIC DIFFERENTIATION OF PERIODONTAL LIGAMENT STEM CELLS IN 3D CELL SHEET

Chamila P. Panduwawala[1], Lakshman P. Samaranayake[2], Lijian Jin[3], Chengfei Zhang[1]
[A]Comprehensive Dental Care, [B]Oral Biosciences, [C]Periodontology and Public Health, [1]The University of Hong Kong, 34, Hospital Road, Sai Ying Pun, HK, Hong Kong

Objective:
To investigate the expression of odontogenic differentiation markers and vascular network formation in 3-D cell sheet with different cell ratios of periodontal ligament stem cells (PDLSCs) and human umbilical vein endothelial cells (HUVECs).
Method:
Human PDLSCs were isolated and characterized by flow-cytometry, and HUVECs were used for construction of cell sheet. Both types of cells were seeded on temperature responsive culture dishes with PDLSCs alone, HUVECs alone, and various ratios of these cells (1:1, 2:1, 5:1 and 1:5) to obtain confluent cell sheet layers. The expression of odontogenic pathway markers including ALP, BSP, RUNX2 were analyzed at 3 and 7 days using RT-PCR. Further ALP protein quantification was done at 7 and 14days using alkaline phosphatase assay. The calcium nodule formation was assessed qualitatively and quantitatively by Alizarin Red assay. Histological evaluations of three cell sheet constructs treated with different combinations (PDLSCs-PDLSCs-PDLSCs/PDLSCs-HUVECs-PDLSCs/Co-Culture 2:1 PDLSCs-HUVECs) were performed with H&E and immunofluorescence straining. Statistical analysis was done by t-test ($p<0.05$).
Result:
Significantly higher ALP gene expression was observed at 3days in 1:1 (PDLSCs:HUVECs) (2.52±0.67) and 5:1(4.05±1.07) co-culture groups compared with other groups($p<0.05$), being consistent with ALP protein quantification. However, BSP and RUNX2 genes expressions were higher at 7days compared to that detected at 3 days. Significant calcium mineralization was detected and quantified by Alizarin red assay at 14days in 1:1(1323.55±6.54µm) and 5:1(994.67±4.15µm) co-cultures as compared with mono-culture cell sheets($p<0.05$). H&E and CD31 immunostaining illustrated the development of a layered cell sheet structure with endothelial cell islands within the constructed PDLSCs-HUVECs-PDLSCs and co-culture groups. Furthermore, HUVECs permeated into layered cell sheet, was suggestive of rudimentary vascular network initiation.
Conclusion: This study suggests that PDLSCs-HUVECs co-culture models exhibit significantly high levels of odontogenic markers with signs of initial vascualar formation. This novel 3-D cell sheet-based approach may be potentially beneficial for periodontal regenerative therapy.

ANGIOGENESIS IN PATIENTS WITH CHRONIC OCCLUSIVE ARTERIAL LOWER LIMBS DISEASE TREATED WITH AUTOLOGOUS STEM CELL AND EXERCISE

carlos franco[1], **Luz Mabel Avila Portillo**[2], Francisco Arroyo[1], Daniel Segura[1], Gonzalo Pullaz[2], Benjamin Ospino[2], Oscar Mauricio Alvarez[1], Jenniffer Priscila Avila[2]
[1]Hospital Militar Central, Bogota, Colombia, [2]Regenerative Medicine Stem Lab, Bogota, Colombia

Introduction:
Chronic occlusive arterial disease (COAD) affecting the lower limbs, is a disease resulting from atherosclerosis, also having the risk of progression to critical ischemia. Many
of these patients are not candidates for revascularization strategies; the stem cell transplantation becomes a viable treatment option.
.**Objectives:**
Evaluate the clinical response
obtained after autologous stem cell (ASCs) transplantation and a walking exercise program, in patients with chronic occlusive arterial disease of lower limbs without possibility of surgical revascularization.
Materials and
Methods: After signing informed
consent 24 patients with unilateral or bilateral COPD without possibility of revascularization (Fontaine II and III), were subjected to an ASCs intramuscular injection, obtained from peripheral blood or bone marrow, all the patients started therapy 3 times a week for 12 weeks at a Low Intensity 85% of maximum heart rate obtained during a stress test or formula 220-age x 85%. With the inclination and speed needed to induce claudication (moderate pain) in the first 3 to 5 minutes with duration of 30 minutes to 60 minutes treadmill with duration: 30 minutes to increase up to 60 minutes. At mode: Walk treadmill. In this study was evaluated the ankle / brachial index (ABI), pain visual analog scale (VAS) and free walking distance claudication (WDC) by comparing pre-transplant, two visits post-implementation and a year after the intervention.
Results:
The first evaluation was done by week 9.1 ± 3.3 and the second to 16.6 ± 5 days post injection. The third assessment was done at week 64.5 ± 4. All patients showed improvement in ABI I(0.52 ± 0.21 to 0.65 ± 0.13 p = 0.0023) and had decreased in the score by VAS of pain (from 9.1 ± 0.67 to 5.67 ± 1.3 p = 0.0000) compared with the first visit; difference increases when comparing the initial state with the second visit (0.52 ± 0.21 to 0.71 ± 0.14 p = 0.0001) for the ABI and VAS (from 9.1 ± 0.67 to 3.22 ± 2.4 p = 0.0000). The decrease in VAS for pain persisted over time even up to the assessment year (from 9.1 ± 0.67 to 2.22 ± 1.3 p = 0.0000). On the march there was a significant increase in distance traveled in meters after transplantation (from 86.2 ± 50.6 to 339.4 ± 119 p = 0.0000) of the significant between groups. There were no adverse effects or complications related to the procedure.
.**Conclusion:**
The autologous stem cells $CD34^{+}$ / $CD133^{+}$ through intramuscular injection plus a walking exercise
program is a clinically feasible and effective strategy to sustainable results in short and medium term, making it
, (viable) suitable tool for the
management of patients with severe lower limb atherosclerosis.

UTILIZING STEM CELLS TO CREATE A NOVEL BLOOD-BRAIN BARRIER MODEL

Ethan Lippmann, Samira Azarin, Abraham Al-Ahmad, Jennifer Kay, Hannah Wilson, Sean Palecek, Eric Shusta

University of Wisconsin-Madison, Madison, WI, United States

The blood-brain barrier (BBB) is composed of brain microvascular endothelial cells (BMECs) which line brain capillaries and control trafficking between the brain and bloodstream via extremely restrictive intercellular junctions and a cohort of transporter proteins expressed by the endothelium. This unique interface is necessary to maintain brain health and homeostasis but presents a significant bottleneck for drug delivery: it excludes ~98% of small molecule therapeutics from reaching the brain. A long-standing goal in the research community has been the creation of a robust human *in vitro* BBB model to utilize for many purposes, including studies of BBB development and regulation and to use in high throughput screening of prospective neuropharmaceuticals. However, issues such as low yields, lack of scalability from primary sources, and poor barrier properties *in vitro* have hindered this field for several decades. To circumvent such problems, we have utilized human pluripotent stem cell (hPSC) technology to construct a high-fidelity BBB model. We developed a protocol for differentiating hPSCs to endothelial cells possessing characteristic BBB markers (GLUT-1, p-glycoprotein) and tight junction proteins (claudin-5, occludin). Derivation of these so-called hPSC-derived BMECs relies on the co-differentiation of neural cells that impart BBB characteristics on the developing endothelium in part via Wnt/β-catenin signaling. Purified hPSC-derived BMECs possess a substantial *in vitro* BBB phenotype, including elevated transendothelial electrical resistance (TEER) in response to co-culture with primary rat astrocytes (up to 1450±140 Ωxcm^2), selective permeability to small molecules of varying lipophilicity that correlates well with *in vivo* uptake, and expression of active efflux transporters. By incorporating other cells of the neurovascular unit into this BBB model, such as human pericytes derived from fetal tissue and human astrocyte/neuron mixtures derived from fetal neural progenitor cells, and optimizing medium conditions, we can further improve TEER up to 5000 Ωxcm^2. Overall, this model could have a variety of applications ranging from basic biological studies to screening candidate drugs for brain uptake.

INDUCED HEMANGIOBLASTS DERIVED FROM EMBRYONIC STEM CELLS EFFECTIVELY IMPROVE VASCULAR REPAIR AND REGENERATION

Fang Liu[1], Suk Ho Bhang[2], Elizabeth Arentson[1], Chan Kyu Kim[1], Inyoung Kang[1], Jinsheng Yu[3], Judy Yoo[1], Nagisa Sakurai[1], Kyunghee Choi[1]

[A]Pathology & Immunology, [B]Department of Biomedical Engineering, [C]Department of Genetics, [1]Washington University in St. Louis, St. Louis, MO, United States

Generation of tissue restricted multipotent progenitors from pluripotent stem cells would be a powerful tool for regenerative applications. As for blood and vessel development, it has been shown that Flk-1+ mesoderm derived from embryonic stem (ES) cell or embryos contains the hemangioblast, a common progenitor of hematopoietic and endothelial cells. Our previous studies suggest that an Ets transcription factor, ER71/Etv2, can specify hemangioblast commitment from Flk-1+ mesoderm at the expense of cardiogenic Flk-1+ mesoderm generation. Herein, we reasoned that homogenous hemangioblast induction from ES cells could be achieved through cooperatively utilizing of defined hemangiogenic factors. By extensively screening of candidate genes preferentially expressed in the hemangioblasts, we were able to detect skewing outcome toward hemangiogenic (Flk-1+PDGFR-alpha-) mesoderm with Er71, Gata2 or Scl enforced expression. Furthermore, we demonstrated that ER71/Etv2, GATA2 and Scl form a core transcriptional network in hemangioblast development and that transient co-expression of these three factors during mesoderm formation stage in mouse ES cells robustly induced hemangioblasts by activating BMP and Flk-1 signaling and inhibiting PI3K and Wnt signaling. “The three factor-induced hemangioblasts” effectively generated hematopoietic and endothelial cells both in culture and in vivo. Importantly, mesenchymal stem cells (MSCs) protected induced hemangioblasts from apoptosis when co-cultured as spheroids and promoted their endothelial cell differentiation by producing VEGF and FGF2 angiogenic factors. Consequently, induced hemangioblasts, when co-delivered with MSCs as spheroids, generated functional endothelial cells and smooth muscle cells in ischemic mouse hindlimbs, resulting in improved blood perfusion and limb salvage. We provide a novel strategy to generate hemangioblasts and tissue spheroids of hemangioblast-MSCs for potential angiogenic repair and regeneration.

HIF1α EXPRESSION IN MULTIPLE ADULT STEM CELL COMPARTMENTS

Natsumi Takahashi, Juanita Mathews, Richard Allsopp
Institute for Biogenesis Research, University of Hawaii, Honolulu, HI, United States

Hypoxia inducible factor 1 alpha (HIF1α) is the principal transcriptional regulator in response to a low oxygen environment, activating a number of target genes for adaptive responses. Previously our group has identified HIF1α as a critical regulator of telomerase reverse transcriptase (Tert), the catalytic component of telomerase, in mouse embryonic stem cells. In the present study, we have begun to investigate the expression of HIF1α in mouse adult stem cell compartments. We observed low but detectable levels in resting c-Kit+Sca1+lineage^{Neg} Thy1.1^{Lo} hematopoietic stem cells (HSC), and readily detectable levels in CD133+ neuronal stem cells (NSC). Furthermore, immunohistochemical and western analysis revealed high levels expression of HIF1α in spermatogonial stem cells in both neonatal and adult testes as well as in both primordial follicles in neonatal ovary and mature oocytes in adult ovary. Exposure of both HSC and NSC to a hypoxic environment in vitro significantly induced Hif1 levels as well as Tert expression and telomerase activity ($P<0.01$). These observations point towards an important role of Hif1 in stem cell behavior, including regulation of telomerase.

W-2012

ASYMMETRIC AND SYMMETRIC REGULATION OF STEM CELL FATES BY HETEROCHRONIC AND WNT/MAPK PATHWAYS IN C. ELEGANS

Omid F. Harandi[1], Victor Ambros[2]
[1]*Medicine, Harvard Medical School/Beth Israel Deaconess Medical Center, Boston, MA, United States,* [2]*Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, United States*

Stem cells can switch between asymmetric (self-renewing) and symmetric (proliferative) cell division patterns and this transition must be tightly regulated for normal development and tissue homeostasis. Many genes that function in invertebrate asymmetric division have been shown to be deregulated in human malignancies and may act to promote proliferation of cancer stem cell by altering the balance between asymmetric and symmetric cell divisions. To genetically assess the role of pathways involved in transition from asymmetric to symmetric cell division, we utilized post-embryonic epithelial stem (seam) cells in *C. elegans* which permits us to study the genetic interactions of factors involved in temporal cell fate decision, self-renewal and polarity at the level of single stem cell *in vivo*. Here, we provide evidence that this transition is regulated by the activity of Wnt and MAPK pathways components, LIT-1/NLK (Nemo-Like Kinase) and POP-1 (TCF), and the temporal control of this transition is regulated by the heterochronic genes LIN-14, LIN-28, and *let-7-family* microRNAs. We propose that the heterochronic genes may modulate the temporal thresholds for LIT-1/NLK and POP-1/TCF activity in the stage-specific of these transitions by maintaining the polarity of APR-1/APC. Our results suggest a new emerging view of regulation of asymmetric to symmetric transition and polarity by heterochronic genes during normal stem cell development which might be deregulated in cancer stem cells.

W-2013

EFFECTS OF DIFFERENT SUBCULTURE TIMES ON CELL PROLIFERATION, REACTIVE OXYGEN SPECIES GENERATION AND APOPTOSIS OF FRESH OR CRYOPRESERVED EMBRYONIC STEM CELLS

Myungook Lee[1], Jung Ki Yoon[1], Jae Hee Lee[3], Seo Jin Oh[1], Ji Yeon Ahn[2], Jeong Mook Lim[1]
[A]*WCU Biomodulation,* [B]*Cancer Research Institute,* [1]*Seoul National University, Seoul, Korea, Republic of,* [2]*Dept of Ob/GYN & Reproductive Biology, Michigan State University, Grand Rapids, MI, United States*

This study was conducted to evaluate the effects of subculture times on cellular competence and cryopreservation capacity of embryonic stem cells (ESCs). Mouse ESCs subcultured either 4 (early passaged) or 19 times (late passaged) were further subpassaged with or without cryopreservation. Cell proliferation, generation of reactive oxygen species (ROS) and incidence of apoptosis were monitored after 1, 2 and 6 subpassages of post-treatment subculture. Faster cell proliferation appeared as shortening of doubling times ($p<0.05$ by PROC-GLM) were detected in the late-passaged ESCs as compared to the early-passaged ESCs, which was accompanied by decreased ATP synthesis. These effects appeared, regardless of cryopreservation, but the difference of each parameter among the treatments disappeared as the post-treatment subculture progressed. The same pattern was detected in ROS generation, but a significant decrease in the generation was observed only in the late ESCs after cryopreservation. There was no remarkable increase in apoptotic cell number between the early-passaged and late-passaged ESCs, but the subculture after cryopreservation further reduced the apoptotic cell number. In conclusion, subculture of ESCs influences cellular activity and subculture repeated at least twice after the designated treatment contributes to the stabilization of ESC activity.

W-2014

A NOVEL POTENTIAL THERAPY FOR VASCULAR DISEASES: DENDRITIC CELLS DIRECT PRO-ANGIOGENIC STIMULATION OF BLOOD-DERIVED STEM/PROGENITOR CELLS

Yael Porat[1], Mark J. Niven[2], Shlomo Bulvik[3]

[1]Hematology BC Stem Cell Research, BioGenCell Sanz Medical Center Laniado Hospital, Netanya, Israel, [A]Bildirici Diabetes Center, [B]Hematology BC Stem Cell Research, [2]Sanz Medical Center Laniado Hospital, Netanya, Israel

Background: Recent data show that dendritic cells (DCs) are important component of stem cell niches in the bone marrow and spleen, and as such may have a role in stem/progenitor cell homeostasis and in pro- and anti-angiogenic processes (Gabrilovich, 1996; Dikov, 2005; Sozzani, 2007). We describe a novel technology for generating a therapeutic population (BGC101) of enriched endothelial progenitor cells (EPCs), using DCs to specifically direct Stem/progenitor cell (SPCs) activity in vitro. This newly developed process makes it possible to use unmobilized blood cells as a source for sufficient numbers of potentially therapeutic stem/progenitor cells within culture for one day.

Methods and results: Selected immature plasmacytoid and myeloid DCs from healthy and diabetic donors, obtained from either the Israel Blood Bank, or Laniado Hospital after receiving signed informed consent approved by hospital's IRB (Bulvik 15/150109), were activated with anti-inflammatory and pro-angiogenic molecules to induce specific activation signals. Co-culturing of activated DCs with SPCs for 12-66 hours generated 83.7±7.4×10^6 BGC101 cells with 97% viability from 250 ml of blood. BGC101, comprising 52.4±2.5% EPCs (expressing Ulex-lectin, AcLDL uptake, Tie2, vascular endothelial growth factor (VEGF) receptor 1 and 2, and CD31), 16.1±1.9% SPCs (expressing CD34 and CD184), and residual B and T helper cells, demonstrated angiogenic and stemness potential and secretion of IL-8, IL-10, VEGF, and osteopontin. When administered intramuscularly to nude mice with limb ischemia, BGC101 yielded a high safety profile and significantly increased blood perfusion, capillary density, and limb function. In the experiment the %perfusion was tested in the vehicle-treated control group, the peripheral blood mononuclear cell (PBMC)-treated group, and the BGC101-1 (1-day culture), BCGC101-3 (3-day culture, high dose), and BGC101-31 (3-day culture, low dose). After 21 days BGC101 treatment doubled the blood flow to the legs from an average of 23±5% after injury to an average of 51±3.1% on day 21 after treatment ($p<0.002$). Cell tracking and biodistribution showed that engraftment was restricted to the ischemic limb.

Conclusions: These observations indicate that alternatively-activated DCs can promote the generation of EPC-enriched SPCs within culture for one day. It is particularly noteworthy that the blood of diabetic patients yielded the same range of numbers and specific cells as that of healthy donors. This is an important finding, as a blood volume of 250 ml can be safely and easily acquired even from patients with anemia. Thus, in addition to its scientific merit the novel technology described here can be expected to facilitate the development of a standardized product with potential clinical applications for treatment of various vascular conditions such as coronary heart disease, stroke and peripheral ischemia.

SMAD3 DEPLETED ES CELL TERATOMA AS A NOVEL MODEL TO STUDY TUMOR DEVELOPMENT

Ping Yuan
Chemical Pathology, Li Ka Shing Institute of Health Sciences, the Chinese Univ of Hong Kong, Hong Kong, Hong Kong

Smad3 depleted ES cell teratoma as a novel model to study tumor development

Disease associated gene knockout embryonic stem cells can serve as valuable in vitro models for the study of disease mechanisms and drug screen. Smad3 mediated TGF-β/Activin/Nodal signaling plays important roles in many biological processes and Smad3-/- mice develop colorectal cancer. But, Smad3 depleted embryonic stem cells have yet to be derived. To exam whether Smad3-/- ES cell can be used to study tumor development, we derive Smad3-/- ES cells. Smad3-/- ES cells display no defect on self-renewal and proliferation. They express similar level of pluripotent genes and lineage genes compared to wild type ES cells. Intriguingly, subcutaneous injection of Smad3-/- ES cells into nude mice leads to formation of malignant immature teratomas, while wild type ES cells tend to form mature teratomas. Microarray analysis shows that Rif1, a key DNA repair factor, is highly upregulated in Smad3-/- ES cells. Smad3 binds to Rif1 promoter region and directly represses its expression. As the elevated expression of DNA repair genes is associated with metastasis of tumor, the upregulation of Rif1 may be responsible for the malignancy of Smad3-/- teratoma. This study uncovers a novel mechanism between smad3 and a DNA repair factor Rif1, and also suggests that transgenic ES cell teratoma may serve as a good model to study the mechanism of tumor development.

W-2017

ISOLATION AND CHARACTERIZATION OF ENDOTHELIAL OUTGROWTH FROM CORONARY ARTERIES IN PATIENTS WITH ACUTE MYOCARDIAL INFARCTION FOR DISEASE MODELING

Susan Gallogly
Scottish Centre for Regenerative Medicine, University of Edinburgh, Edinburgh, United Kingdom

Background: Endothelial dysfunction is one of the earliest pathological features in atherosclerosis and predisposes to intra-vascular thrombosis, ischemia and infarction. Our understanding of endothelial cell biology is derived mainly from the study of commercially available human umbilical vein endothelial cells (HUVECs). However, HUVECs are not involved in atherosclerosis and provide only limited insight into the pathogenesis of coronary artery disease. We describe a novel method for the isolation of coronary artery endothelial cells from thrombectomy specimens obtained during the treatment of patients with acute myocardial infarction.
Objective: To isolate, expand and characterise coronary endothelial outgrowth (CEO) cells and compare these cells to HUVECs, in order to investigate the potential of CEO cells as a model of human endothelial dysfunction.
Method: Patients presenting to the Royal Infirmary of Edinburgh with ST-segment elevation myocardial infarction (n=15) who underwent emergency percutaneous coronary intervention and thrombus aspiration were recruited. Thrombus specimens were manually dissected, plated onto collagen-I coated plates and maintained in endothelial growth media to encourage cellular outgrowth. Growth kinetics (population doubling time) was evaluated and cells were fixed and immunostained. A multiparameter flow cytometric analysis using monoclonal antibodies to endothelial cell markers was performed (CD31-FITC, KDR-PE, CD146-PE/Cy7 and CD34-APC/Cy; percent positive expression). Angiogenic potential was assessed using an established method of tubule-like structure formation on a basement membrane matrix (Matrigel).
Results: Outgrowth of coronary artery endothelial cells was observed in 9/15 samples. CEO cells were maintained for a minimum of 38 days in culture (mean=4512 days). Populations doubling times of CEO cells were comparable to HUVECs (mean±SD: CEO 2.6±0.5, HUVEC 2.3±0.1 days; p=0.50 student's t-test). CEO cells had typical "cobblestone" morphology and were immunoreactive for the endothelial specific glycoprotein vWF. Surface expression of CD31 and KDR was comparable in both CEO cells and HUVECs (CD31 mean±SD: CEO 74.9±21.3 vs. HUVEC 89.3±11.4, p=0.13; KDR mean±SD: CEO 46.7±31.7 vs. HUVEC 22.2±15.9, p=0.11) whereas CD146 and CD34 expression was increased in CEO cells compared to HUVECs (CD146 mean±SD: CEO 96±5.3 vs. HUVEC 73.5±30.7, $p<0.05$; CD34

mean±SD: CEO 80.9±16.92 vs. HUVEC 40.63±18.06, p<0.001). Limited angiogenic potential was observed in CEO cells with only 4/9 (44%) capable of tubule formation compared to 10/10 (100%) of HUVECs (p=0.01, contingency tables and fishers exact test). CEO cells that were capable of tubule formation had reduced capacity to form connections compared to HUVECs (mean±SD: CEO 12±8, versus HUVEC 63±16 connections; p<0.0001).
Conclusion: Viable coronary arterial endothelial cells can be isolated from thrombus extracted during emergency percutaneous coronary intervention. These cells have a mature endothelial phenotype comparable to control endothelial cells, but have reduced angiogenic potential suggesting they retain the functional characteristics of *in situ* endothelium. This novel approach to isolate dysfunctional endothelial cells may have applications in drug screening and in future studies may provide additional insight into the cellular and molecular basis of endothelial dysfunction in patients with coronary artery disease.

IN VIVO AND IN VITRO STUDY OF MIGRATORY CAPABILITY OF HUMAN MESENCHYMAL STROMAL CELLS TOWARDS HEPATOCELLULAR CARCINOMA AND FIBROSIS.

Juan M. Bayo Fina[1], Esteban J. Fiore[1], Flavia Piccioni[1], Mariano Marrodan[1], Marcela Bolontrade[2], Estanislao Peixoto[1], Rodrigo LLoyd[1], Miguel Rizzo[1], Laura Alaniz[1], Jorge Aquino[1], Osvaldo Podhajcer[3], Mariana Garcia[1], Guillermo Mazzolini[1]

[1]Gene Therapy Laboratory, School of Medicine, Austral University, Derqui, Argentina, [2]Laboratory of Molecular and Cellular Therapy, Fundación Instituto Leloir, Buenos Aires, Argentina, [3]Laboratory of Molecular and Cellular Therapy, Fundación Instituo Leloir, Buenos Aires, Argentina

Hepatocellular carcinoma (HCC) represents 85% to 90% of liver primary tumors and is the third-leading cause of cancer-related death in the world. Moreover, the incidence and mortality associated with HCC continues increasing worldwide. In most cases, HCC is developed in patients with liver cirrhosis; for this reason this condition is considered a preneoplasic stage. The hepatocarcinogenesis process involves an extensive exchange of signals between the tumor cells and their microenvironment, which is composed by several cell types, including hepatic stellate cells. Particulary, several proinflammatory cytokines, chemokines and growth factors, which are produced by tumor and stroma cells, are involved in this crosstalk. It is known that mesenchymal stromal cells (MSC) have the ability to migrate in response to most of these soluble factors. The aim of this work was to study the *in vitro* and *in vivo* migration capability of MSCs towards HCC in order to use them for delivery of therapeutic genes. For that purpose, *in vitro* migration was studied by modified Boyden chamber, observing that MSC displayed a higher migration towards conditioned medium (CM) derived from fresh human samples of HCC compared with CM derived from non tumoral tissue. MSCs also showed a high ability to migrate towards CM derived from ex vivo tumors generated in nude mice by the inoculation of HuH7 cell lines or a primary culture of HCC (HC-PT-5). We also found an increased migration to CM derived from liver or tumors derived from animals with liver fibrosis and intrahepatic tumors, when compared with the CM obtained from healthy mice. In order to evaluate hMSC *in vivo* migration, HCC cell line HuH7 was inoculated subcutaneously (s.c.) or intrahepatically (i.h.) in BALB/c nude mice. HuH7 tumors were also developed by intrahepatic inoculation in animals with subjacent fibrosis, induced by the administration of thioacetamide (i.h. TAA). Once tumors have developed, CMDiI-DiR-labeled hMSCs were intravenously injected and biodistribution was monitored by fluorescence imaging (Xenogen In Vivo Imaging System). Seven days later, healthy and tumor bearing mice were sacrificed and MSCs were found in spleen, liver and lungs. Animals with tumors also presented MSCs signal in tumors. Moreover, liver and tumors from i.h. TAA mice showed a stronger signal compared with the other groups. These results were confirmed by microscopy fluorescence visualization of CMDiI+ cells in the isolated organs. Our results indicate that factors produced by HCC and fibrotic liver induce higher hMSC migration both *in vivo* and *in vitro*, compared with lungs and spleen, which showed a lower signal. Taking together, our results indicates that soluble factors present in the tumor milieu induce the recruitment of MSC to HCC, making these cells a promising candidate for effective cellular delivery of therapeutic genes, not only against HCC but also fibrosis.

BONE MARROW MESENCHYMAL STROMAL CELLS (BM-MSCs) PROMOTE PANCREATIC CANCER GROWTH AND CLONOGENICITY IN VITRO

Roula Antoon[1], Xing-Hua Wang[2], Yoko Kosaka[3], Sowmya Viswanathan[3], David Hedley[4], Armand Keating[1]
[1]Cell Therapy Program, Princess Margaret Hospital/Ontario Cancer Institute,University Health Network, Institute of Medical Science, University of Toronto, Toronto, ON, Canada, [2]Cell Therapy Program, Princess Margaret Hospital/ Ontario Cancer Institute, University Health Network, Toronto, ON, Canada, [3]Cell Therapy Program, Princess Margaret Hospital/Ontario Cancer Institute,University Health Network, Toronto, ON, Canada, [4]Princess Margaret Hospital/Ontario Cancer Institute,University Health Network, University of Toronto, Toronto, ON, Canada

Introduction: Heterotypic interactions between pancreatic
cancer cells (PCCs) and tumor stroma are critical for pancreatic cancer development and progression. MSCs are multipotent stromal progenitors that may selectively migrate and home to primary and metastatic tumor sites. Little is known about the contribution of BM-MSCs to pancreatic tumor growth and development. Here, we evaluate the paracrine effect of human BM-MSCs on pancreatic tumor growth, apoptosis and clonogenic potential. In addition, we investigate PCC/BM-MSC interactions
via Sonic Hedgehog (Hh) and canonical Wnt signaling mechanisms**.** Hh and Wnt signaling are implicated in pancreatic cancer growth and
progression.
Methods: PCCs from Mia-Paca-2 (undifferentiated), Panc-1 (poorly differentiated) and BXPC3 (moderately differentiated) cell lines were plated on 0.4 um transwell inserts and co-cultured with hBM-MSCs at 1:1 ratio in basic medium with 10% FBS for 48-72 hrs. Tumor cells alone and dermal fibroblast (FB) co-cultures were used as controls. Apoptosis was evaluated by DilC1. Cell proliferation was assessed by Click-iT EdU. Clonogenic assays were performed by culturing 5000 tumor cells in methylcellulose. Experiments were repeated 3 times in triplicate. Hh and Wnt signaling were evaluated by western blot (WB) and RT-PCR.
Results: BM-MSCs significantly promoted the growth of Mia-Paca-2 enhancing tumor cell proliferation by 37% ($P<0.0001$) and reducing
tumor cell apoptosis by 3.4% ($P<0.02$) versus tumor alone but
showed little or no effect on Panc-1 or BXPC3 cell lines. BM-MSCs promoted Mia-Paca-2 cell cycle entry, increasing the number of cells in S phase by 32% ($P<0.005$) compared with tumor cells cultured alone. In addition, BM-MSC co-cultures significantly enhanced the frequency of Mia-Paca -2 colony forming cells in methylcellulose by 1.6 fold versus tumor alone. There was little or no difference between tumor cells cultured alone or co-cultured with FB. The BM-MSC growth promoting effect was associated with increased levels of cyclin E1 and c-Myc proteins in co-cultured tumor cells as shown by WB. RT-PCR and WB show that BM-MSCs have little or no effect on Hh and Wnt activity in co-cultured tumor cells versus controls.
Conclusion: Under our experimental conditions, BM-MSCs promoted pancreatic cancer growth, increased tumor clonogenicity and reduced tumor cell apoptosis in a cell line dependent manner via soluble factors. This growth promoting effect may have been due to increased cyclin E1 and c-Myc expression in Mia-Paca-2 cells in co-culture with BM-MSCs but not via the Hh or Wnt signaling pathways which were similarly active, in Mia-Paca-2 alone, or in co-culture with BM-MSCs. Elucidating the molecular mechanisms by which hBM-MSC support pancreatic tumor growth and the pathways triggered by pancreatic cancer/stromal interactions may lead to identifying new therapeutic targets.

MESENCHYMAL STROMAL CELLS (MSCS) IN EXPERIMENTAL SEVERE BURN INJURY: IMPROVEMENT OF SURVIVAL, WOUND HEALING AND MODULATION OF IMMUNE CELLS

CAROLINA C. OLIVEIRA[1], JULIANA U.N. YAOCHITE[1], DANIELA CARLOS[1], REINALDO BATISTA[2], DAIANE F. SANTOS[3], KELEN MALMEGRIM[3], FERNANDO Q. CUNHA[1], MARCO A.C. FRADE[4], EDUARDO A. DONADI[1], JÚLIO C. VOLTARELLI[1]
[A]Biochemical and Immunology, [B]Clinical Analysis and Bromatology, [C]Center of Cell-Based Therapy, [D]Clinical Medicine, [1]Sao Paulo University, Ribeirao Preto, Brazil

Background: Skin damage by severe burns triggers a cascade of events that cause both local effects and systemic responses. These responses lead to a complex biological event involving both resident skin cells and leukocyte subsets. In this context, MSCs are good candidates to cell therapy for burns wounds due to their regenerative potential (differentiation and paracrine effects) and immunomodulatory properties. **Aim:** Evaluating the therapeutic potential of xenogeneic MSCs in the treatment of experimental model of severe burn injury. **Methods:** MSCs were isolated from the bone marrow of FVB GFP+ mice and expanded *in vitro* in α-MEM plus 15% FCS. Wistar rats were submitted to experimental burn through the dorsal contact of a brass bar (200°C for 25s). $5x10^6$ MSCs or PBS were given via intradermal in animals belonging to the treatment group (TG) and the control group (CG), respectively. All analyses were performed at 7, 15, 30 and 45 days after burn. The wound healing area (day 60) was evaluated by the software ImageJ®. $CD4^+$ and $CD8^+$ T cell subsets in the spleen and wound area were evaluated by flow cytometry and neutrophils counts by MPO dosage. Serum levels of IL-10, TGF-β and CINC-1 were examined by ELISA. **Results:** TG showed a higher survivor rate (61.54%) than CG (46.67%), p=0.002. Sixty days after injury the wound healing percentage in TG animals (90.81 ± 5.054; n=7) was higher than in the CG (76.11 ± 3.457; n=7), p = 0.03. MSC treatment induced increased serum levels of TGF-β at day 15 (p=0.02), whereas IL-10 (p=0.05) and CINC-1 (p<0.001) on day 30. We observed an alteration of the CD4/CD8 ratio in CG at 7 (p= 0.004) and 15 days (p=0.035) post-burn, comparing to the TG. We also observed decreased frequency of $CD4^+$ T cells at day 7^{th} (p=0.024), 15^{th} (p=0.031) and 45^{th} post-burned (p=0.008) and decreased frequency of $CD8^+$ T cells at day 7^{th} (p=0.02) post burned (p=0.02), in wound area of TG animals. In this group, we also showed increased neutrophils counts in the damaged area at day 45^{th} after burn (p=0.016). **Conclusion:** These results demonstrate the efficiency of MSCs treatment by improving wound healing and modulating immune cells in severe burns. This evidence may provide the basis for regenerative therapy with allogeneic MSCs as a prompt and effective therapeutic alternative for major burned patients with need of immediate care.

ANTIOXIDATIVE EFFECTS OF KINETIN AND EPIGALLOCATECHIN-3-GALLATE IN HUMAN MESENCHYMAL STEM CELLS

Yu-Jen Chang[1], Ji-Ying Leu[2], Mei-Ling Wu[1], Ching-Ping Tseng[2], Shiaw-Min Hwang[1]
[1]Food Industry & Development Inst, Hsinchu, Taiwan, [2]Department of Biological Science and Technology, National Chiao Tung University, Hsinchu, Taiwan

Mesenchymal stem cells (MSCs) are the multipotent stem cells that can give rise to mesenchyme-lineage cells, such as osteoblasts, adipocytes, chondrocytes and myoblasts. MSCs can be isolated from various tissues and have been represented as a promising cell source for cell therapy. It is essential to get the large cell numbers and high activity of MSCs to meet the potential demands for clinical applications. In spite of the strong self-renewal property, MSCs undergo cellular senescence during expanded cultivation in vitro. It is well-known that the oxidative stress induced cell aging during lifespan. In this study, we focused on the relationship between cellular oxidative status and cultivated senescence in bone marrow-derived MSCs (BMMSCs) and cord blood-derived MSCs (CBMSCs). We examined the cellular oxidative stress by culturing cells with antioxidants, kinetin and epigallocatechin-3-gallate (EGCG). To understand the effects of antioxidants supplementation on MSCs, the results of growth status, reactive oxygen species (ROS) value, and lipid peroxidation were analyzed in BMMSCs and CBMSCs. We found that kinetin and EGCG treated MSCs expressed similar surface marker profiles with normal culture condition. The results also showed that the lower oxidative status, the higher catalase activity, and the longer lifespan could be found in kinetin cultivation than control condition in both types of MSCs. However, there were no obvious differences between MSCs cul-

tures with or without EGCG addition. In differentiation test, the osteogenesis could be enhanced by kinetin and the adipogenesis could be inhibited by EGCG in both types of MSCs. Moreover, kinetin but not EGCG decreased the anti-aging marker β-galactosidase in late passage of BMMSCs and CBMSCs. These results indicated that kinetin could be a useful additive to reduce cell oxidative status during MSCs expansion.

INTRAVENOUS HUMAN ADIPOSE STEM CELL GRAFTS PROTECT THE BRAIN FROM NEURODEGENERATION, MOTOR AND COGNITIVE IMPAIRMENTS: BIODISTRIBUTION OF HADSC IN YOUNG AND AGED RATS

Sandra A. Acosta[1], Naoki Tajiri[1], MD Shahaduzamman[1], Kazutaka Shinozuka[1], Hiroto Ishikawa[1], Mibel Pabon[1], Lisa Gould[2], Niketa Patel[2], Denise Cooper[2], Yuji Kaneko[1], Paula C. Bickford[3], Cesar V. Borlongan[1]
[1]Neurosurgery, Center of Excellence for Aging and Brain Repair, Department of Neurosurgery and Brain Repair, University of South Florida College of Medicine, Tampa, FL, United States, [2]James A. Haley Veterans Affairs Medical Center, Tampa, FL, United States, [3]Neurosurgery, Center of Excellence for Aging and Brain Repair, Department of Neurosurgery and Brain Repair, University of South Florida College of Medicine. James A. Haley Veterans Affairs Medical Center, Tampa, FL, United States

Traumatic brain injury (TBI) survivors exhibit neurological, motor and neurocognitive symptoms from the primary injury which can become aggravated over time due to secondary cell death. In the present in vivo study, we examined the beneficial effects of human adipose stem cells (hADSCs) in a controlled cortical impact (CCI) model of mild TBI using young and aged (20 months) F344 rats.
Young and aged male F344 rats were treated with 4x106 ADSCs (Tx), conditioned media (CM) or control media (M) at 3 hours post CCI. A separate cohort of animals with the same treatments received DiR-labeled hADSCs. hADSC's labeled with DiR were imaged using the IVIS imager at 1, 4, 12, 24, 48, and 72 hrs post-transplant, with organs separately imaged at the end of the study. At day 0 - 7, post TBI, groups underwent motor tests and at Day 7 cognitive assessment tests, then at day 11, all groups were euthanized and brain tissues harvested.
Significant amelioration of motor and cognitive functions was revealed in young Tx and CM groups but there was less improvement in aged rats Tx relative to TBI rats that received the control media treatment (M). Fluorescent (FL) imaging revealed hADSC's moved to organs and brain within 1 to 12 hours following TBI. In aged rats decreased FL was seen in spleen, however higher FL was observed in brain at 12 - 72 hours post TBI. The impact volume in cortex was found to be significantly reduced in young Tx and CM relative to control treatment. However in aged rats this effect was decreased and only Tx reduced impact volume. Furthermore, the percentage of intact peri-impact area in cortex revealed a significant amelioration in both young Tx and CM treated and old Tx and CM rats in compare with control M. In addition, there was a decrease of hippocampal CA3 pyramidal neuron loss in both Tx young and Tx old rats compared to control M. To further elucidate the mechanism of CM actions, we examined CM from hADSC's grown with antisense RNA to two long noncoding RNA's (lncRNA) known to play roles in gene expression and shown to be secreted by our hADSC's. CM reduced in either NEAT1 or MALAT1 were less effective in preventing motor behavior loss and did not reduce infarct or peri-infarct lesion size.
Results show that hADSCs is a promising therapeutic intervention to rescue against TBI-induced behavioral and histological impairments with better functional recovery in young animals, likely due to robust migration of the transplanted cells to peripheral organs quickly in young animals despite increased stem cell recruitment to the aged ischemic brain. In addition, lncRNA secreted in exosomes from hADSC's are a candidate for mechanism of action of the hADSC's to rescue against TBI-induced injury.

STABILIZATION OF BETA-CATENIN IN MTERT-EXPRESSING DENTAL STEM CELLS RESULTS IN SUPERNUMERARY TOOTH FORMATION AND ECTOPIC DENTIN FORMATION

Diana L. Carlone, Rebecca D. Riba-Wolman, Dana M. Ambruzs, Samantha Stewart, David T. Breault
Endocrinology, Boston Children's Hospital, Boston, MA, United States

Adult stem cells play an integral role in the regeneration of a variety of tissues including the mouse incisor. We have recently reported that telomerase (*Tert*) expression marks self-renewing stem cells in blood, intestine and putative bone marrow-mesenchymal stem cells. Based on these findings, as well as a recent report of telomerase activity within putative human dental stem cells, we hypothesized that *mTert* is a biomarker for stem cells within teeth. To investigate whether *mTert*-expressing cells are present in postnatal teeth and function as stem cells in the continual renewal of the mouse incisor, we performed lineage-tracing studies using *mTert*-rtTA :: oTet-Cre :: R26R $^{flox(mT/mG)/+}$ trigenic mice. Our results indicate that *mTert*-expressing cells in the upper incisor give rise to both ameloblasts and odontoblasts indicating that *mTert* expression separately marks epithelial as well as mesenchymal dental stem cell populations. Interestingly, in the lower incisor *mTert* expression marks only mesenchymal stem cells suggesting that discrete stem cell populations exist within each region.
The canonical Wnt/beta-catenin signaling pathway plays an important role in regulating tooth formation and renewal such that activation or repression of this pathway results in altered tooth number and location in both humans and mice. Stabilization of beta-catenin specifically within *mTert*-expressing cells and their progeny using doxycycline-inducible *mTert*-rtTA :: oTet-Cre :: Catnb$^{flox(ex3)/+}$ mice resulted in supernumerary tooth formation at the apical (incisal) end of the incisor. Interestingly, analysis of the incisor dental papilla from these mice showed ectopic dentin formation suggesting that stabilization of beta-catenin within mesenchymal-derived *mTert*+ cells promotes odontoblast differentiation. Finally, preliminary observations indicate these mice also exhibit premature suture fusion and altered calvarial bone formation suggesting *mTert*-expressing cells may play a more global role in craniofacial tissue function/maintenance. Additional studies are currently underway to determine the role of PTEN in regulating Wnt signaling and tooth stem cell function. Supported by the National Institute of Dental and Craniofacial Research (1R21DE022420-01A1) awarded to DLC.

VALIDATION OF IN VIVO TUMORIGENICITY TEST FOR THE PROCESS CONTROL OF CELL/TISSUE-ENGINEERED PRODUCTS USING SEVERE IMMUNODEFICIENT NOG MICE

Shinji Kusakawa[1], Kazuhiko Machida[2], Satoshi Yasuda[3], Takuya Kuroda[3], Rumi Sawada[4], Hideki Tsutsumi[2], Shin Kawamata[1], Yoji Sato[3]

[1]Foundation for Biomedical Research and Innovation, Kobe, Japan, [2]Central Institute for Experimental Animals, Kawasaki, Japan, [A]Division of Cellular and Gene Therapy Products, [B]Division of Medical Devices, [3]National Institute of Health Sciences, Tokyo, Japan

Contamination of tumorigenic cells is one of the major concerns in manufacturing process of cell/tissue-engineered products. However, no quantitative evaluation method for tumorigenicity of cell/tissue-engineered products has been established Utilizing of severe immunodeficient mouse strains such as NOD/Shi-scid IL2Rg^{null} (NOG) mice, as xenogenic hosts for tumorigenicity testing to detect a trace amount of tumorigenic cells in products, is worthy of attention. NOG mice have shown highly engraftment potential as compared with conventional immunodeficient mouse strains, such as nude mouse and NOD/scid mouse, which are recommended as rodent xenotransplantation models to assess tumourigenicity of mammalian cells as substrates for the manufacture of biological medicinal products in WHO Technical Report Series, No. 878.. Based on such evaluations, we will be able to assess the capability and the extent of the coverage of the tumorigenicity test. In the present study, to evaluate the sensitivity of the tumorigenicity test using NOG mice, we examined tumor formation of xenotransplanted HeLa cells in NOG (T, B, and NK cell-defective) and the traditionally used nude (T cell-defective) mice. The tumorigenicity of HeLa cells in both immunodeficient mouse strains was evaluated by measuring some parameters that represent the tumorigenic phenotype: tumor-forming capacity, tumor latency and tumor size for 16 weeks. Tumor-forming capacity is defined by quantitative, dose-response, tumorigenicity assays that yield the $\log_{10}$ 50% tumor-producing dose (TPD_{50}) as endpoint values, which represent the limiting or threshold dose of cells that form tumors in 50% of the animals. NOG mice are highly susceptible to tumor induction by HeLa cells (TPD_{50} = 4.1 [approximately 1.3 x 10^4 cells]). In contrast, nude mice showed ~33-fold less tumorigenicity (TPD_{50} = 5.6 [approximately 4.2 x 10^5 cells]) of HeLa cells

compared with NOG mice. NOG mice inoculated with HeLa cells suspended in Matrigel, a basement membrane-like extracellular matrix extract, showed ~5400-fold higher tumorigenicity (TPD_{50} = 1.9 [approximately 80 cells]) of HeLa cells, compared with nude mice. Next, we applied this method to the validation of the sensitivity of tumorigenic cells contaminated in normal human cells (human mesenchymal stem cells (hMSC)). NOG mice were inoculated with HeLa cells (0, 10^1, 10^2, 10^3, 10^4 cells) serially diluted in Matrigel with hMSC (10^6 cells), leading to the TPD_{50} value comparable to that in NOG mice inoculated HeLa cells only. These results indicate that the combination of NOG mice and Matrigel can detect tumorigenic cells with extremely high sensitivity and suggest the usefulness of NOG mice for *in vivo* tumorigenicity test.

GENERATION OF INDUCED PLURIPOTENT STEM CELLS FROM HUMAN CIRCULATING MULTIPOTENT STEM CELLS

Han-Mo Yang, **Ju-Young Kim**, Joo Eun Lee, Hyun-Jae Cho, Yoo-Wook Kwon, Jin Hur, Sang Eun Lee, Sahmin Lee, Jung-Kyu Han, Chang-Hwan Yoon, Young-Bae Park, Hyo-Soo Kim
Seoul Natl Univ Hosp, Division of Cardiology, Seoul, Korea, Republic of

Background: The discovery of induced pluripotent stem (iPS) cells has opened up new possibility of molecular understandings for development and therapeutic applications for patient-specific disease. One of the important issues for clinical applications is cell source. Human peripheral blood is one of the easy accessible cell sources. However, isolated peripheral blood cells have shown low gene transfection efficiency and inconveniences requiring specific methods to isolate. Here, we report a novel population of peripheral blood-derived stem cells, which can be easily reprogrammed to iPS cells.
Methods and Results: We freshly isolated peripheral mononuclear cells (PBMC) from human peripheral blood and seeded on the fibronectin-coated plate. We observed adherent cells from as early as 5 days after the start of culture and those cells gradually formed colonies. We were able to isolate these cells with very high efficiency. Furthermore, we have also confirmed that these cells can be differentiated to osteogenic, adipogenic, and myogenic-lineage cells. Therefore, we named these cells circulating multipotent adult stem cell (CiMS). We were successful in generating iPS cells with these cells. These cells showed enhanced efficiency of gene transduction, compared to the human dermal fibroblast. We obtained reprogrammed colonies (CiMS-iPS) in 8 days after 4 factor virus transduction without feeder cells. We identified CiMS-iPS had similar features to embryonic stem cell in morphology, gene expression, epigenetic state and ability to differentiate into the three germ layers. We obtained more than 40 iPS cell lines from PBMC of patients with cardiovascular disease and normal volunteers.
Conclusions: Our study showed new methods to isolate stem cells from peripheral blood and to generate iPS cells with high efficacy. This suggests that our new approach could be one of ideal methods for clinical application of iPS cells in future.

W-2028

ENGINEERED HUMAN EMBRYONIC STEM CELLS FOR INDUCIBLE GENE EXPRESSION

Vera Alexeeva[1], Wilson Young[2], Carlos Filipe Pereira[1], Ihor R. Lemischka[1], Sunita L. D'Souza[1], **Christoph Schaniel**[3]
[A]Developmental and Regenerative Biology, [B]Medicine, [C]Pharmacology and Systems Therapeutics, [1]Icahn School of Medicine at Mount Sinai, New York, NY, United States

Human embryonic stem cells (hESCs) and induced pluripotent stem cells (hiPSCs) hold great promise for biomedicine. They provide an unlimited source of cells to model not only early human development but also various human diseases. They can be differentiated with varying efficiencies to various mature cell types for the development of disease biomarkers and novel therapeutic strategies. However, the lack of genetic tools similar to those proven useful in dissecting out the complexities of mouse development and differentiation has hampered the realization of the full potential of hESC/hiPSC technology.

In order to develop tools for hESC/iPSC research, we generated hESC lines for inducible transgene expression. We engineered the human H9 ESC line (also known as WA09; NIH registration number 0062) to express M2rtTA constitutively from the human ROSA26 locus on chromosome 3 using transcription activator-like effector nuclease (TALEN) pair to target the human ROSA26 locus between exon 1 and exon 2 with a donor plasmid. This donor plasmid comprised a splice acceptor - M2rtTA - poly adenylation (pA) cassette that is followed by an FRT-flanked phosphoglycerine kinase (PGK) promoter driving hygromycin resistance - pA cassette to facilitate the selection of clones and to allow its subsequent removal in correctly targeted clones. Targeting efficiency using this specific TALEN pair was 86%. Expression and functionality of M2rTA was ensured by infecting the targeted H9 cells with FUWtetO-mOrange lentiviral particles that carry a Doxycycline (Dox)-inducible TetO promoter driving mOrange expression. As expected, all correctly targeted clones showed mOrange expression after Dox-induction (1.5 µg/mL) for 2 days, while mOrange expression was not observed in an incorrectly targeted clone. However, co-infection with FUWtetO-mOrange and FUW-M2rtTA, which confers expression of M2rtTA via the constitutively expressed Ubiquitin C promoter, induced strong mOrange expression after Dox-addition even in this incorrectly targeted line. Ongoing experiments are focusing on investigating the titratability of induction and the ability to induce transgene expression in differentiated cells. In addition, we are targeting the human AAVS1 locus with a cassette that will enable Cre-recombination mediated cassette exchange to place any gene or combination of genes under the control of the Dox-inducible TRE promoter.
This cell line will allow us to study the effect of inducible transgene expression and/or knockdown of various genes during human development and differentiation, thus providing a valuable resource for the stem cell community.

W-2031

AUTOMATED ANALYSIS AND SORTING OF HUMAN iPS CELL CLUSTERS BY LARGE PARTICLE FLOW CYTOMETRY

Francis Smet[1], Paul Wanek[2], Stephanie Sontag[2], Simone Haupt[3], Michael Peitz[3], Rico Bongaarts[1], Oliver Brüstle[3], Rock Pulak[4], **Martin Zenke**[2]
[1]Union Biometrica, Geel, Belgium, [2]Institute for Biomedical Engineering - Cell Biology, RWTH Aachen University, Aachen, Germany, [3]Institute for Reconstructive Neurobiology, Life & Brain, Bonn, Germany, [4]Union Biometrica, Holliston, MA, United States

The generation of induced pluripotent stem cells (iPS cells) from somatic cells is one of the most dynamic fields in biomedicine. iPS cells show appealing promises for disease modeling, pharmacological screening and eventually cell replacement therapy. Yet, to fully take advantage of iPS cell technology several bottlenecks need to be overcome: Traditionally, biotechnology procedures aim at producing one product in large quantities, but iPS cell technology requires the simultaneous production of several hundreds or even thousands of individual iPS cell clones. This is particularly important when it comes to the identification of iPS cell clones, which harbor the disease-specific mutations.
Frequently, standard procedures for iPS cell production are based on manual processing, such as picking of iPS cells and/or clusters. Further approaches use immunomagnetic beads and column-based selection of single cells, which however results in loss of iPS cell clonality. Thus, there is clearly the need to develop procedures and protocols for fully automatic isolation and simultaneous processing of a large number of individual iPS cell clones.
The StemCellFactory project (www.stemcellfactory.de) aims to fully automate by robotics (i) the generation of human iPS cell lines and (ii) their differentiation into cardiomyocytes and neuronal cells. Here we evaluated large particle flow cytometry technology (BioSorter, Union Biometrica) for iPS cell isolation, including multiparametric quality assessment of isolated cells. The large particle flow cytometry instrument is capable of sorting cells and cell clusters ranging from 2-1500 micrometer. The fluid pressures of the instrument (up to 6 psi) are significantly lower than those of traditional flow cytometers, which results in cells/cell clusters being exposed to much lower shearing forces than during conventional single cell flow cytometry.
Human iPS cells were established with Oct4, Sox2, c-Myc and Klf4 reprogramming factors in Sendai virus vectors on feeder layer. iPS cell colonies were stained with the FITC-labeled pluripotency marker TRA-1-60, collagenase treated and cell clusters were subjected to sorting by flow cytometry with the BioSorter device. Cell clusters were sorted

according to size and TRA-1-60 expression and multiple parameters were assessed, and individual cell clusters were deposited in 96 well format. The analysis was fast and dispensing to wells of multiwell plates was fully automated, taking about 20 min for a 96 well plate. Sorted cells were efficiently expanded over several passages as clonal iPS cell lines and evaluated by morphology, expression of pluripotency markers and their growth and differentiation potential. This establishes Biometria's large particle Biosorter flow cytometer as a versatile device for analysis and sorting of primary iPS cell colonies.
The authors for the StemCellFactory Consortium (www.stemcellfactory.de).

METALLIC NANOPARTICLES AS LABELS FOR MESENCHYMAL STEM CELLS: EVALUATION OF BIOCOMPATIBILITY.

L. H. A. Silva[1], G. A. Ferreira[2], F. D. Cruvinel[2], E. C. O. Lima[2], R. B. Azevedo[1], J. R. Silva[1], D. M. Oliveira[1]
[1]University of Brasília, Brasília, Brazil, [2]Federal University of Goiânia, Goiânia, Brazil

Recently, labeling and subsequent tracking of stem cells in vivo has risen as a non-invasive alternative technique that answers the best site of inoculation of the cells for a given condition, their pattern of distribution within the organism and how effectively they migrate towards pathologically affected sites. Some examples of materials commonly used as markers are metallic nanoparticles, such as gold and iron oxide nanoparticles. Considering that metallic nanoparticles can be toxic or compromise the physiology / metabolism of receptor cells, it becomes important to conduct preliminary studies of biocompatibility before marking and tracking stem cells in vivo. Thus, our study aimed to test the biocompatibility between gold and iron oxide nanoparticles and human mesenchymal stem cells (hMSCs), by evaluating the amount of cells that remain viable after exposure to different concentrations of the markers: iron oxide nanoparticles were diluted in DMEM low glucose (supplemented with 10% of fetal bovine serum) at 0,015; 0,03; 0,06 and 0,08 mg/mL, whereas gold nanoparticles were diluted at 0,001; 0,0025 and 0,008 mg/ml in the same medium. The hMSCs were incubated with those solutions during 02, 06 and 24 hours. Then, firstly, the MTT (3-(4, 5-dimethylthiazol-2-yl) 2, 5-diphenyl tetrazolium bromide) cleavage assay was performed to verify changes in the mitochondrial activity of cells. Secondly, to draw a parallel between cellular membrane integrity and the amount of tracer incorporated, "Trypan blue method" and "Prussian blue method" were performed. Ultimately, was made a light microscopy analysis of morphology of hMSCs exposed to the nanoparticles, after 02 and 24 hours, in order to verify signs of apoptosis. The association of the gold nanoparticles with the hMSCs was verified by confocal microscopy while iron oxide nanoparticles, by Prussian blue staining. Our MTT results showed that at least 96% of the cells remained viable even on the higher concentrations of iron oxide tested; whereas the gold nanoparticles also were not toxic: more than 94% of hMSCs remained viable. The same were observed in Trypan blue results: 91% of hMSCs exposed to Iron Oxide remained alive while 96% of cells exposed to gold nanoparticles survived. The morphology of hMSCs remained unchanged regardless of the concentration of nanoparticles and the exposure time, furthermore typical features of apoptosis were not observed. Further studies about the effects of these metallic nanoparticles between on MSCs will be performed, such as electron microscopy analysis, cell differentiation tests and cell proliferation assays, in order to characterize those materials for their use as label to track MSCs.

W-2033

USING ISOGENIC PLURIPOTENT STEM CELL DERIVED MOTOR NEURONS AS A MODEL FOR AMYOTROPHIC LATERAL SCLEROSIS.

Jackson Sandoe, Luis Williams
Harvard University, Cambridge, MA, United States

Amyotrophic lateral sclerosis (ALS) is the most common late-onset motor neuron disease and is characterized by the selective degeneration of cortical and spinal motor neurons. A majority of ALS cases are idiopathic however 10% are familial in nature. Of the familial cases, approximately 20% are due to dominant mutations in SUPER OXIDE DISMUTASE 1 (SOD1). We set out to use stem cell technology as a tool for modeling familial SOD1 ALS in vitro.

Because of documented variability amongst pluripotent cell lines, we used nuclease mediated gene targeting to either introduce an SOD1 A4V-encoding mutation in control human embryonic stem (hES) cells or correct the same endogenous mutation in ALS patient induced pluripotent stem (iPS) cells. We show correct expression of the SOD1 locus in both pluripotent stem cells and motor neurons after gene targeting. A prominent feature of familial SOD1 ALS is the formation of detergent-insoluble SOD1 aggregates. Using motor neurons derived from the isogenic pluripotent cell lines we show the presence of insoluble SOD1 segregating solely with the SOD1 A4V-encoding mutation under conditions of proteasome inhibition. We further investigate other common pathologies of ALS including motor neuron survival and neurite morphology. Our results demonstrate that isogenic pluripotent cell lines provide a valuable resource for ALS disease modeling.

W-2034

LAMININ-521 IS THE OPTIMAL CHOICE FOR PLURIPOTENT CELL CULTURE SINCE IT ENABLES EASY AND RELIABLE SINGLE-CELL PASSAGING OF HES AND IPS CELLS WITHOUT ARTIFICIAL INHIBITORS

Jesper Ericsson, Yi Sun, Kristian Tryggvason
BioLamina, Sundbyberg, Sweden

Laminins are a group of 16 protein isoforms found in the basement membrane in the extracellular matrix. The natural environment for all stationary cells in the body consists of other similar cells and the basement membrane. Laminins are the only tissue-specific proteins in the basement membrane and therefore one critical factor that differentiates one niche from another.
Laminin-521 is one of the first extracellular matrix proteins already expressed by the cells of the inner cell mass in the blastocyst. Our data shows that when using Laminin-521 to create a niche on cell culture plates, pluripotent hES and iPS cells can be grown indefinitely in a pluripotent state. This is the first xeno-free, defined and biologically relevant matrix that truly supports hES or iPS cells in a robust way in cell culture.
Laminin-521 also has growth factor like properties and human ES and iPS cells cultured on Laminin-521 grow twice as fast compared to all other tested matrices. Also due to the biological properties of Laminin-521, stem cells cultured on Laminin-521 can be split 1:20 or up to 1:30 as single cells without the addition of artificial ROCK inhibitor, which can push genetical variations to cell populations.
In conclusion, we show that Laminin-521 is an optimal matrix for hES and iPS cell culture due its biological relevance that allows long-term pluripotent cell growth with single cell passaging without any artificial inhibitors that may modify the cell population.

NEW STRATEGY FOR TRACING IMPLANTED STEM CELLS IN VIVO

Jongkai Hsiao[1], Hon-Man Liu[2], Ming-Jium Shieh[3], Min-Feng Wei[4], Chen-Wen Lu[5], Dong-Ming Huang[6]
[1]Department of Medical Imaging, Tzu-Chi General Hospital, Taipei Branch, New Taipei City, Taiwan, [2]Department of Medical Imaging, National Taiwan University Hospital, Taipei, Taiwan, [3]Department of Internal Medical, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, [4]Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, [5]Department of Life Science, National Taiwan Normal University, Taipei, Taiwan, [6]Center for Nanomedicine Research, National Health Research Institutes, Miaoli, Taiwan

Stem cells gives potential opportunity for tissue repair and organ transplantation. For tissue repair, the cells are delivered into the body either locally or systemically. Visualizing these cells in vivo is thus critical for monitoring its existence and function.
Iron oxide nanopartitles have been used widely for tracing stem cells under magnetic resonance imaging (MRI). Stem cells must ingest plenty amount of nanoparticles for being visualized in MRI. Some critics upon alteration of cell function and behavior has been published. The real existence of the cells has also been challenged since the

cell releases its nanoparticles once if the cell dies. We developed another strategy for monitoring the live stem cells with genetic engineering technique to let these cells shine in MRI.
The following studies are done in vitro and has been proved by the biosafety committee. We use human mesenchymal stem cells from bone marrow and transfect these cells with one novel gene that can capture gadolinium based MR contrast agent. The transfection is inert to cell behavior. The differentiation function is preserved after transfected cell exposed to MR contrast agent. We can observe bright signal that originates from the uptake of gadolinium chelates into the cells. These cells has the ability to transport these gadolinium chelates into extracellular space.
We conclude that transfection of gene that regulates gadolinium chelates is an efficient and practical tool that can be used for cell trafficking. Future animal study is essential for comparison with nanoparticle based trafficking methods.

DEVELOPMENT OF HIGH QUALITY cGMP-GRADE HUMAN STEM CELLS FOR HUMAN DISEASE AND TRANSLATIONAL RESEARCH

Shayne Boucher[1], Alex Kharazi[2], Nikolai Tankovich[2], Soojung Shin[1], David Kuninger[1], Mohan Vemuri[1]
[1]Primary & Stem Cell Systems, Life Technologies, Frederick, MD, United States, [2]Stemedica Cell Technologies, San Diego, CA, United States

Quality and functionality of adult stem cells used in human disease research vary considerably due to non-standardized cell derivation protocols. Considerable variance exists with donor source, tissue processing, primary cultivation, and potency, and can generate results that are difficult to replicate and lead to inconclusive findings. To address this issue, we tested various approaches to optimize production of consistent lots of highly purified, rapidly expanding primitive adult stem cells under cGMP conditions that can be utilized as a cell standard or in disease research.
As hypoxia appeared to be beneficial for hMSC cultures (Ma et al 2009; Das et al 2010; Basciano et al 2011), we compared hMSC expanded under normoxic (20% O_2) and hypoxic (5% O_2) conditions. At Passage 2 and 4, hMSC yielded 2 fold and 1.5 fold increase in cell number when cultured under hypoxic condition as compared to normoxic condition. We also observed 1.7 fold increase in the number of colonies in CFU-F assays when cultured under hypoxic condition. Further expansion was realized when we incorporated media components with good lot-to-lot consistency and high unit activity.
Hypoxic hMSC should meet minimal criteria for multipotent MSC (Dominici et al 2006). Therefore, we analyzed hypoxic hMSC by flow cytometry for evidence of >95% MSC surface markers (CD73, CD90, CD105, CD166), <5% non-MSC surface markers (CD14, CD19, CD34, CD45), and <5% MHC class II marker (HLA-DR). At all passages, the hMSC exceeded minimal criteria. Differentiation studies confirmed ability of hypoxic hMSC to generate adipogenic, osteogenic and chondrogenic lineage cell types. In addition, a karyotype analysis was performed and no gross abnormalities were observed.
Since there is considerable interest in reparative capacity of hMSC, we performed a cytokine profile on normoxic and hypoxic hMSC. For angiogenic factor VEGF and chemoattractive factor SDF-1, we observed a significant increase under hypoxic condition versus normoxic condition (VEGF: 9.17±0.67 vs 7.67±0.86 ng/millCells/24 hours; SDF-1: 12.2±1.01 vs 9.2±1.27 ng/millCells/24 hours). These increases suggest that hypoxia endows hMSC with angiogenic- and migratory-inducing properties.
By employing an optimized cultivation and potency testing protocol during scale up expansion, we can start with 2 million cells from a Passage 2 master bank and yield 1.5 billion cells at Passage 4. This translates into a working bank size of 100 vials of 1.5e7 viable cells/vial within 14 days. We have established consistency of this system over forty lots of Passage 4 cells.
We have demonstrated the expansion of adult stem cells at larger scale following optimized standardized protocols without losing their intrinsic stem cell nature. With this source of well-characterized, consistent and potent adult stem cells, investigators can make meaningful comparisons in their disease research studies, drug screening assays,

and design of effective cell-based therapies. These cells are now being used or will be used in Phase I/II clinical trials (ClinicalTrial.gov ID NCT01297413, NCT01770613, NCT0177167). Similar scale up approaches are being applied to human neural stem cells and human retinal pigment cells for the research and treatment of neurologic and ophthalmic disorders.

W-2038

ENHANCED HOMING OF MESENCHYMAL STEM CELLS TO BRAIN TUMORS

Christopher Smith[1], Benjamin Lin[1], Saksham Gupta[2], Thomas O'Donnell[2], Sagar Shah[1], Kaisorn Chaichana[3], Alfredo Quiñones-Hinojosa[3], Andre Levchenko[1]

[A]Biomedical Engineering, [B]Neuroscience, [C]Neurosurgery, [1]Johns Hopkins University, Baltimore, MD, United States

Introduction: Brain cancer is a devastating ailment, leading to more than 1,300 deaths in the United States each year. Glioblastoma (GB) is the most common and aggressive type of primary brain cancer in adults. Despite the use of standard treatments, such as radiation, chemotherapy, and surgical resection, GB displays characteristic recurrence, followed by swift fatality within two years. In the search for more effective therapies, recent studies have specifically targeted multipotent adult mesenchymal stem cells (MSCs) to brain tumor (glioma) microenvironments. MSCs have obtained significant interest as drug delivery tools due to their intrinsic tropism for tumors in vivo. The ability of MSCs to breach the blood brain barrier (BBB) provides the unique potential to treat brain disorders, namely brain cancer. Despite these advantages, the efficiency of MSC homing to the brain has been limited, hindering the feasibility of such therapies. We hypothesize that modulation of MSCs can enhance their delivery to the brain.

Methods: Our studies employ commercial and primary-cultured human adipose-derived mesenchymal stem cells (hAMSCs), which benefit from less invasive isolation than bone marrow-derived cells. Utilizing novel micro- and nanotechnology, e.g. microfluidics and patterned cell substrates, we developed intricate in vitro models to analyze the multi-step process by which hAMSCs reach tumors. Our experiments have specifically investigated the putative MSC homing steps of firm adhesion, transendothelial invasion, migration, and chemotaxis. We analyzed effects on these processes by soluble factors in glioma-conditioned medium (GCM), and by the extracellular matrix (ECM) proteins, fibronectin and laminin. Finally, we examined the effects of these factors on homing in vivo using orthotopic animal models of human glioma.

Results: Through exposure of hAMSCs to soluble and immobilized proteins, we have observed enhanced homing in vitro. hAMSC adherence to blood vessel endothelium, measured by numbers of flowing cells that attach to endothelial monolayers, is improved following pre-exposure to GCM and fibronectin ($p \leq 0.05$). After this preconditioning, hAMSCs also demonstrate enhanced transendothelial invasion towards GCM through a model of the BBB ($p \leq 0.05$). Other results show enhanced migration (measured by speed, alignment, and persistence) of hAMSCs pre-exposed to GCM and laminin ($p \leq 0.05$). In addition, hAMSC chemotaxis towards GCM gradients intensifies following GCM preconditioning ($p \leq 0.05$). Combining these treatment techniques in vitro induced enhancements in all of the homing steps described above ($p \leq 0.05$). Preliminary in vivo results suggest increased localization of hAMSCs to glioma xenografts in mice, following combined pretreatment techniques, and subsequent injection into the bloodstream.

Conclusions: Our results demonstrate that specialized culturing methods can enhance specific elements of the MSC homing process, which may lead to in vivo applications. This approach mirrors previous reports that have improved engraftment to other target tissues, e.g. the heart. Uncovering methods to improve tissue-specific MSC localization could revolutionize drug delivery for various diseases.

W-2041

HIGH THROUGHPUT PRODUCTION OF HUMAN MESENCHYMAL STEM CELL SPHEROIDS WITH CONTROLLABLE MICROENVIRONMENT VIA DOUBLE-EMULSION BASED DROPLET MICROFLUIDICS

Hon Fai Chan[1], Ying Zhang[1], Yi-Ping Ho[2], Youngmee Jung[1], Ya-Ling Chiu[1], Kam W. Leong[1]

[1]Biomedical Engineering, Duke University, Durham, NC, United States, [2]Interdisciplinary Nanoscience Center (iNANO),Biomedical Engineering, Aarhus University, Aarhus, Denmark

Multicelluar spheroids play an important role in stem cell research as they better recapitulate three-dimensional tissue than conventional monolayer culture in enabling greater cell-cell and cell-matrix interactions. Moreover, exogenous substrates and growth factors also contribute to directing stem cell behavior. As such, there is an interest for high-throughput generation of stem cell spheroids along with fine tuning of their differentiation potential via controlling exogenous substrate and growth factors supplied, which can be achieved in microfluidics system. This study reports the application of microfluidics-generated double-emulsion (DE) droplets, with a configuration of water-in-oil-in-water, as a picoliter-sized bioreactor for rapid cell aggregation and control of microenvironment for spheroids culture. Human mesenchymal stem cells (hMSC) assembled to form single aggregate in the droplets within two hours and could be subsequently released with over 95% viability. The size of hMSC spheroids could be controlled by varying the input cell density. Precursor gel solution can be adopted as the inner phase to produce spheroid-encapsulated microgels after spheroid formation. The selectively permeability of the oil layer retains growth factors within the droplets, which can subsequently be encapsulated in the microgels for controlled release. The encapsulation of hMSC spheroids in alginate and alginate-RGD hydrogel has been demonstrated to facilitate hMSC differentiation towards various lineages. In summary, the technology facilitates high-throughput production (20Hz) of hMSC spheroids with minimal reagent input including gel solution and growth factors in picoliter-sized DE droplets for fine tuning of microenvironment. The compatibility of this technology with different hydrogels system renders it attractive for screening optimal microenvironmental conditions to advance stem cell tissue engineering.

W-2042

A SERUM-FREE, XENO-FREE, DEFINED MEDIUM FOR EFFICIENT EXPANSION OF HMSCS ON A SYNTHETIC SURFACE

Paula Dolley-Sonneville, Lori Romeo, Zara Melkoumian
Corning Incorporated, Corning, NY, United States

There is a great interest in application of human mesenchymal stem cells (hMSCs) in cell therapy and tissue engineering due to their properties of self-renewal, multipotency, immunomodulation, and trophic potential. One of the challenges faced in the clinical application of hMSCs is the need for efficient *in vitro* expansion of these cells without altering their properties.

Traditionally, hMSCs are cultured *in vitro* on tissue culture treated (TCT) plastic in culture medium supplemented with fetal bovine serum (FBS). Due to the undefined nature of FBS, there is variability in hMSC cultures, as well as risk for pathogen contamination, a major safety concern for clinical applications.

To address these concerns, several chemically-defined, serum-free media have been developed and commercialized. However, most of these media require pre-coating of culture vessels with biological substrates, such as fibronectin, to enable hMSC adhesion in serum-free conditions. Coating of culture vessels with biological substrates is challenging and labor intensive for large scale cell production and can also contribute to variability in cell performance.

This study describes a novel serum-free, xeno-free, defined medium, Corning® stemgro® hMSC medium, for hMSC culture. Stemgro hMSC medium enables efficient attachment and expansion of hMSCs without the need for biological coating of culture vessels. Cell performance (cell number, viability, population doublings, immunophenotype, and multipotency) in stemgro hMSC medium was compared to cells cultured in traditional 10% FBS medium. Our results show significantly higher yield (>100 fold) of human bone marrow derived MSCs (hBMSCs) when cultured in stemgro hMSC medium compared to 10% FBS. Importantly, hBMSC expanded in stemgro hMSC medium for >5 serial passages retained stable doubling time, typical elongated spindle-like morphology, surface markers profile, normal karyotype, and multipotency.

We believe stemgro hMSC medium in combination with the synthetic surface (Corning® CellBIND® Surface) provides a complete serum-free, xeno-free, defined culture environment for efficient expansion of high quality hMSCs for both research and therapeutic applications.

W-2043

EXPANSION OF ADULT BONE MARROW-DERIVED MESENCHYMAL STEM CELLS IN THE QUANTUM SYSTEM PRODUCES THERAPEUTIC DOSES UNDER HYPOXIC CONDITIONS

Boah Vang, Brian Nankervis, Kim Nguyen
Terumo BCT, Lakewood, CO, United States

The large numbers of *ex vivo* expanded cells that are required in many clinical cell therapy protocols (>100 million per patient) make standard culture conditions problematic and expensive, resulting from the need for extensive personnel and facility resources and the high potential for contamination. To meet such clinical demand, a robust, automated and closed cell expansion method is optimal. The Quantum Cell Expansion System (Quantum System) is a functionally closed, automated hollow fiber bioreactor system designed to reproducibly grow adherent cells in either Good Manufacturing Practice (GMP) or research laboratory environments. The Quantum System has successfully been used for the *ex vivo* expansion of clinical-scale quantities of adult bone marrow-derived mesenchymal stem cells (MSC) under normoxic conditions.
This study was a proof-of-concept that MSC may be ex cultured on the Quantum System using different coating reagents [fibronectin (FN, BD Biosciences) and cryoprecipitate (CPPT, Bonfils)] in a hypoxic environment of 5% O_2, 20% CO_2, and balance N_2. Three different donors were expanded for multiple passages. Bioreactor coating with FN or CPPT, cell loading, attachment, feeding, and harvest followed standard Terumo BCT protocols developed for the culture of MSC. Gas concentrations in the closed-loop perfusion system was carefully monitored and characterized. Experimental results demonstrate that therapeutic doses of MSC can be achieved under hypoxic conditions in the Quantum System while maintaining phenotypic characteristics of MSC by flow cytometry, morphology, and tri-lineage differentiation as defined by ISCT.

W-2044

GENERATING OPTIMAL PSEUDOURIDINE AND 5-METHYLCYTIDINE MODIFIED MESSENGER RNAS FOR IPSC REPROGRAMMING

Jiehua Zhou[1], Maggie Bobbin[1], Julie Escamilla-Powers[2], Eric Arnold[3], Anthony Lauer[4], Laura Juckem[4], Karl-Dimiter Bissig[5], **Anton McCaffrey**[2], John Rossi[1]
[1]Department of Molecular and Cellular Biology, Beckman Research Institute of the City of Hope, Duarte, CA, United States, [A]Research & Development, Cell Biology, [B]Chemistry, [2]TriLink BioTechnologies, Inc., San Diego, CA, United States, [3]Mirus Bio, Madison, WI, United States, [4]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX, United States

Recently, there has been significant interest in messenger RNA (mRNA) for gene therapy applications as well as for the generation and manipulation of stem cells. Several groups have shown that mRNAs are attractive vehicles for therapeutic gene expression in mammals. Additionally, Warren et al. demonstrated highly efficient induced pluripotent stem cell (iPSCs) generation by transfection of mRNAs encoding reprogramming factors. mRNAs have no risk of insertional mutagenesis and subsequent oncogenesis. Thus, the authors suggested that iPSCs generated using mRNA should be safer than iPSCs derived by plasmid transfection or viral transduction.
A key insight regarding mRNA expression systems was the recognition that mRNAs induce innate immune responses in transfected cells. Kariko et al. showed that substitution of uridine and cytidine residues with pseudouridine and 5-methlycytidine dramatically reduced innate immune recognition of mRNA and pseudouridine modified RNA was translated more efficiently and had increased nuclease resistance.
These studies highlight the importance of development of stable, non immunogenic mRNA to support these applications. In this current study, we synthesized capped pseudouridine and 5-methlycytidine modified mRNAs expressing Klf4, c-Myc, Sox2, Lin28, Oct4, Luciferase and GFP at 10 mg scales. Fluorescence activated cell sorting (FACS) demonstrated >95% transfection in HEK-293 cells. Expression in BJ fibroblasts, MRC-5 fibroblasts, human CEM T-cells and CD34+ hematopoietic stem cells was also achieved. Transfected mRNAs showed a surprising long duration

of expression (up to 8 days post-transfection). We compare the transfection efficiency and toxicity associated with 14 days of repeated transfection of fibroblasts using several transfection reagents and find high transfection efficiency and low toxicity with TransIT®-mRNA (Mirus Bio). Repeated transfection with Klf4, c-Myc, Sox2, Lin28 and Oct4 produced robust stem cell colonies. Similar methodologies are applicable to the generation of differentiation factor mRNAs to drive iPSCs down different lineages.
Gene therapy applications of mRNA will require scalable purification methods that are able to produce mRNAs at gram scales. Recently, it was shown that purification of mRNA by HPLC dramatically reduced innate immune responses relative to unpurified mRNA. Here we compare mRNA purified by classical silica membrane chromatography to HPLC purified materials. HPLC reveals that in vitro transcribed mRNAs may contain complex mixtures of subspecies.

AN OXYGEN GRADIENT LANDSCAPE GENERATED IN A MICROFLUIDIC DEVICE DEMONSTRATES CROSSTALK BETWEEN NORMOXIC AND HYPOXIC STEM CELLS

Megan Rexius[1], Asrar B. Malik[2], Peter Toth[2], Navdeep S. Chandel[3], David T. Eddington[1], Jalees Rehman[2]
[A]Bioengineering, [B]Pharmacology, [1]University of Illinois at Chicago, Chicago, IL, United States, [2]Medicine, Northwestern University, Chicago, IL, United States

Tissue ischemia is characterized by gradients in the level of oxygen ranging from extreme hypoxia at the primary site of injury to reduced ischemia and even normoxia at the edges or penumbrae. Tissue hypoxia is the primary physiological stimulus for angiogenesis. Homogenous hypoxia is known to increase secretion of pro-angiogenic vascular endothelial growth factor (VEGF) expression in human mesenchymal stem cells (MSCs) which can activate angiogenesis in endothelial cells. Here using a novel microfluidic device in which oxygen gradients could be finely tuned to simulate varying levels of tissue ischemia, we addressed the question whether paracrine crosstalk occurs between cells exposed to varying oxygen levels by studying close proximity interactions between normoxic and hypoxic cells.
Our cell culture platform with precise control of oxygen gradients allows different oxygen levels to be selectively applied to cell types in a co-culture (e.g. one cell type can be hypoxic while the other is normoxic), while permitting paracrine interactions between the distinct cell types via shared cell culture media. The gas-permeable cell culture platform was designed as an integrated, multilayered device. Validation of the oxygen profile of the gradient was performed using a fluorescent oxygen sensor. Production of pro-angiogenic vascular endothelial growth factor (VEGF) was used as a readout to determine whether normoxic cells influence nearby hypoxic cells. Immunofluorescent staining and quantitative PCR were used to assess alterations in gene expression in an oxygen gradient versus homogenous oxygen levels. An oxygen-dependent-domain green fluorescent protein construct enabled real-time monitoring of Hypoxia Inducible Factor (HIF) expression.
We observed that hypoxia-induced upregulation of VEGF in MSCs was suppressed by close-proximity normoxic MSCs. Also in co-cultures of hypoxic MSCs and normoxic microvascular endothelial cells (MVECs), normoxic endothelial cells prevented VEGF expression. Importantly, hypoxic upregulation of the glucose transporter (Glut1) expression, a HIF-induced gene, in MSCs was not affected by the normoxic cells. The abrogation of the response in the hypoxic cells was, therefore, not the result of inhibition of a HIF response. Thus, neighboring normoxic cells suppress cellular hypoxia-induced VEGF expression in MSCs via the release of transmissible factors. These findings suggest the ability of MSCs in ischemic tissue to promote endothelial cell proliferation and tissue regeneration through VEGF generation is dictated by the release of paracrine factors by the nearby normoxic MSCs. In this sense, the oxygen landscape into which MSCs are transplanted is likely to be a key determinant of their regenerative function. Our microfluidic cell culture platform can be leveraged to study paracrine interactions across an oxygen gradient. Our ongoing experiments are now applying this technology to study hypoxic responses of embryonic and induced pluripotent stem cells in an oxygen landscape.

MICRORNA PROFILING AS A QUALITY SIGNATURE FOR CELLULAR THERAPIES

Vincent O'Brien, Daria Olijnyk, David Mallinson, Sarah Paterson, Susan Ridha
Sistemic Ltd, Glasgow, United Kingdom

Stem cells derived from embryonic or adult tissue and from reprogrammed somatic (iPS) cells have significant promise for regenerative medicine. However, despite similarities in developmental potential, several groups have found fundamental differences between stem cell lines that could impact on the potency and/or safety of the resultant cell populations but which were not predicted using current monitoring procedures based on flow cytometry and analysis of panels of mRNAs. There is a requirement for reliable tools to monitor cell populations during the processes of stem cell line development, directed differentiation and scale-up to safe, therapeutically-useful cell populations. MicroRNA (miRNA) profiling is proving highly informative for cell characterisation and cell therapy developers are now exploring using miRNA profiling for product characterisation. Using a variety of miRNAome discovery technology platforms combined with subsequent verification and validation using alternative technologies, Sistemic has developed a novel, reliable, generic monitoring tool (SistemQC™) that provides both a robust indication of cell identity, homogeneity and potency as well as providing insights into the underlying changes in gene expression associated with observed biological phenotypes. SistemQC™, utilises a combination of microRNA expression profiling and customised, multi-layered data analysis to provide a simple, robust and cost-effective tool to monitor the maintenance of pluripotency in stem cell lines across passage, the staging of directed differentiation from embryonic, iPS or direct reprogramming strategies and, post scale-up, an assessment of functional attributes and safety profile of the cells. Data will be presented to support these applications.

MEDIUM-THROUGHPUT MICRORNA SCREENS FOR THE IDENTIFICATION OF MOLECULAR TARGETS AND MECHANISMS LINKED TO HUMAN PLACENTA-DERIVED ADHERENT CELL HEALTH

Kathy Karasiewicz-Mendez[1], Xu Dong Lee[2], Timothy Maguire[2], Martin Yarmush[2], Robert Hariri[1], Stewart Abbot[1], Xiaokui Zhang[1]
[1]Celgene Cellular Therapeutics, Warren, NJ, United States, [2]Rutgers University, Piscataway, NJ, United States

Background: MicroRNAs (miRs) are small, non-coding RNA molecules that regulate gene expression at the level of translation. The binding of miRs to complementary regions in the 3' untranslated regions of their target mRNAs results in translational interference or transcript degradation. A striking feature of miRs is the ability of single miRs to target multiple genes and pathways, with the potential to affect numerous biological functions or responses. Herein we describe a medium-throughput human miR- mimic library screen (1,090 miRs), and subsequent bioinformatics analysis, to identify the molecular targets and mechanisms linked to Placenta-derived adherent cells (PDAC) responses to cellular stress conditions.
Methods: Cell health was deliberately perturbed by overnight incubation of PDAC with 100% normal rat serum and apoptosis was monitored by measuring caspase 3/7 activity.
For primary screening, PDAC were transfected with the Ambion Pre-miR Mimic Library (miRBase v15) for 24 hours prior to overnight exposure to 100% normal rat serum. PDAC were stained with Hoechst 33342 and imaged using an InCell Analyzer 2000 (GE) to enumerate nuclei and cells, followed by staining with Caspase-Glo 3/7 to assess caspase 3/7 activity/cell. Hits were defined as miRs that significantly lowered PDAC caspase 3/7 activity/cell vs. either of the Ambion negative controls ($p<0.05$, Student's t-Test).
Secondary confirmation studies included repetition of caspase 3/7 activity/cell assays in combination with additional assessments of metabolic activity and mitochondrial membrane potential. Bioinformatic analyses were used to generate a list of putative target genes of the confirmed miR hits, prior to further validation using Taqman Gene Expression Assays, siRNA knock-down, cell cycle analysis, and flow cytometric measurements of cell cycle proteins.
Results and Conclusions: Our results demonstrated that exposure of PDAC to 100% rat serum significantly increases caspase 3/7 activity, decreases metabolic activity, and decreases mitochondrial activity. We have identified three miRs (miR-29a, miR-16, and miR-424) that alleviated cell stress as indicated by a significant decrease in Cas-

pase 3/7 activity. Secondary screening confirmed that modulation of caspase 3/7 was associated with increased metabolic activity and increased mitochondrial membrane potential. Target gene prediction for these miRs identified hundreds of genes for subsequent pathway analyses and has indicated that down-regulation of cyclins and other cell cycle regulation genes, and induction of quiescence, could protect against specific inducers of cell stress e.g. exposure to rat serum. Furthermore, gene expression studies together with cell cycle and cyclin analysis of PDAC transfected with miR mimics of miR-29a, miR-16, and miR-424 support this hypothesis. Modulation of miRs and their targeted genes/pathways may represent novel approaches for maintaining or augmenting cell health.

MOLECULAR IMAGING OF THE MESENCHYMAL STEM CELLS MIGRATORY PROPERTIES TOWARDS DIFFERENT PATHOLOGIES.

Carolina Belmar-Lopez[1], Georges Vassaux[2], Jerome Burnet[3], Juan Carlos Ramirez[4], Miguel Quintanilla[5], Antonio de la Vieja[6], Santiago Ramon y Cajal[7], Javier Hernandez-Losa[8], **Pilar Martin-Duque**[9]

[1]I+CS. Instituto de Investigación Sanitaria de Aragón, Zaragoza, Spain, [2]Université de Nice Sophia Antipolis, Nice, France, [3]Cancer Research-UK, London, United Kingdom, [4]Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, [5]Instituto de Investigaciones Biomédicas "Alberto Sols" CSIC, Madrid, Spain, [6]ISCIII, Madrid, Spain, [7]Pathology, Hospital Vall d'Hebron, Barcelona, Spain, [8]Pathology, Hospital Vall d´Hebron, Barcelona, Spain, [9]Biotechnology, Francisco de Vitoria´s University/ I+CS. Instituto de Investigación Sanitaria de Aragón/ Fundación Araid, Madrid, Spain

Bone marrow-derived mesenchymal stem cells (MSCs) are multipotent adult stem cells from mesodermal origin that are present within the bone marrow stroma. MSCs are capable of multilineage differentiation under appropriate stimuli. Due to their ease isolation and their pluripotent nature, MSCs are an ideal source for clinical and regenerative medicine approaches in a great variety of applications. One characteristic of MSCs is their capacity to migrate and to proliferate within areas of inflammation and tumours, as part of the tissue remodelling process.
STUDY´S OBJECTIVE: In this report, we demonstrate that when labelled mesenchymal stem cells are injected systemically by intravenous injection and simultaneously into different animals with various pathologies, they tend to migrate naturally to the damaged tissue, independently of the pathology.
METHODS: To prove this hypothesis, we performed in vitro and in vivo imaging techniques by using a broad range of reporter genes (GFP, hNIS and R-Luc) and non-invasive techniques (PET, BLI or fluorescence).
RESULTS: MSCs migrated to the expected target organs and engrafted tumours, targeted the pancreas (in case of diabetes) or went to the skin (in case of injury/wound healing). We were not able to detect signalling in any other organs at the different time points, but changes in the intensity of the signal along the course of the experiment were observed.
CONCLUSIONS: The results suggest that MSCs possess migratory capacity to damaged areas independently of the pathology and that they could be used to enhance tissue repair.

W-2051

QUALITY CONTROL AND TRACEABILITY OF PLURIPOTENT STEM CELL CULTURE THROUGH AUTOMATED COLONY IMAGING

Audrey Nifenecker[1], Olivier Feraud[2], Eva Planes[1], Nicolas Bensid[1], Elsa Raban[1], Emilie Gobbo[2], Noufissa Oudrhiri[2], Annelise Bennaceur-Griscelli[2], **Yates Frank**[1]

[1]CellTechs Research Laboratory, Sup'Biotech School for Bio-Engineering, VILLEJUIF, France, [2]ESTeam Paris Sud Core Facility, INSERM UMR_S935, Univ Paris Sud 11, VILLEJUIF, France

Because pluripotent stem cells can self-renew and proliferate indefinitely, it is essential to ensure that regular quality control steps are performed to assess their healthy and pluripotent status. Quality characterization of pluripo-

tent stem cells usually relies on a standard series genetic (karyotyping, CGH⋯), phenotypic (immunostaining, gene expression analysis...) and functional (teratoma, in vitro diffentiation...) assays. However, one key method used in laboratories consists in visually inspection of the morphology of stem cell colonies during cell culture under the microscope. Although not sufficient in itself to provide a functional assessment of the quality of a cell line in culture, the morphology of unstained colonies remains the easiest and most common method of qualifying the status of pluripotent stem cells in culture. Laboratories working with induced pluripotent stem cells (IPSC) end human embryonic stem cells (hESC) are however confronted with the lack of objective, user-independent parameters to describe the morphological criteria associated with undifferentiated, fully pluripotent stem cells.
We present here a visual atlas of IPSC colonies representative of the states which can be observed during long term culture of IPSC, and propose a nomenclature in order to establish a consistent description of the morphological characteristics of each colony. By taking advantage of an automated microscopy technique (CellCelector, ALS) we also propose a strategy to document the status of a cell culture based on whole-plate phase contrast microphotography. Whole plate microphotography can be used to individually trace, identify and grade all the colonies present on a cell culture plate. By attributing a “pluripotent morphology score” to whole cell plates, rather than a randomized manual visual inspection, we thus endeavour to be able detect the atypical derivation of IPSC lines which can occur during culture, mostly due to genetic or epigenetic abnormalities. This work will be the basis for setting up a computer-assisted colony scoring system via Pattern Recognition Image Analysis. Associated with our morphological scoring system, the CellCelector automated system may also be used to perform automated or semi-automated mechanical IPSC colony picking and passaging, thus ensuring a reliable and reproducible method for long-term culture and batch amplification of IPSC.

EXTRACTING NORMALIZING GENES IN MOUSE EMBRYONIC STEM CELLS FROM SINGLE CELL RNA SEQUENCING DATA

Matan Sorek, Eran Meshorer
The Hebrew University of Jerusalem, Jerusalem, Israel

Measuring gene expression is a fundamental requirement in biology. Quantifying expression at the transcript level usually involves quantitative reverse-transcription PCR (qPCR). In the stem cell field, experimental variability is particularly high, because it frequently involves differentiation to different cell types, which change their entire expression map. Therefore, finding good controls for standardization and for the elimination of experimental variability is a difficult task. Two different approaches were previously proposed, namely, to normalize to one or more reference genes, and to normalize to the input RNA. Since the latter method is more complex and does not resolve the variability induced by the reverse-transcription process, identifying stable reference genes is superior. Previous studies addressed this by selecting a small set of ‘housekeeping’ genes. These were then ranked, using qPCR, according to their stability, typically based on their pairwise correlations. Recent advances in high-throughput sequencing methods enabled the development of whole-transcriptome single cell RNA-seq approaches, which provide an unprecedented opportunity to develop advanced, unbiased normalizing algorithms. Here we developed an approach that utilizes this information to select normalizing genes more accurately. Analyzing 3 different single cell RNA-seq datasets, we find new reference genes in mouse embryonic stem cells (mESC), which are significantly more reliable than the commonly used reference genes. We demonstrate that commonly used genes such as Gapdh, Actin and Tubulin show high variability when compared with our novel normalizers. We also expand this analysis and provide novel general reference genes for a wider range of cells, not limited to the stem cell field. Our algorithms have thus every potential to set new guidelines for standardization in studies involving gene expression measurements.

W-2053

EFFICIENT DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS INTO PAX7 POSITIVE MUSCLE PROGENITORS USING PROTOCOLS DERIVED BY MULTIPLEXED COMBICULT TECHNOLOGY

Marina Tarunina, Jey Jaykumar, Davide Danovi, Tom Watson, Yen Choo, Massimiliano Cerletti

ProgenitorLabs Ltd & Plasticell Ltd, Stevenage Bioscience Catalyst, Stevenage, United Kingdom

Muscle progenitors derived from human embryonic stem (hES) cells offer a renewable source of cells for drug screening and potentially for cell therapy. Here we describe the development of novel defined feeder-free protocols to direct differentiation of hES cells into skeletal myogenic progenitors with the ability to further differentiate into functional muscle. New differentiation protocols were identified through a proprietary combinatorial cell culture technology (CombiCult®, Plasticell). hES cells were cultured on microcarrier beads through more than 10000 distinct combinations of culture conditions to identify protocols that resulted in high differentiation efficiency into muscle progenitors. Tracking of conditions was achieved via concomitant labeling of microcarrier beads using nanomaterial tags. Isolation of microcarriers bearing Pax7 positive cells and tag deconvolution indicated protocols for mesoderm induction, mesoderm differentiation and myogenic lineage differentiation. Muscle progenitors produced by highly efficient protocols were further characterized with respect to cell surface marker expression and regenerative properties. We describe an innovative stem cell technology that allows exploration of signaling pathway regulation with small molecules during stem cell differentiation. Its use with skeletal muscle in particular will speed up the derivation of cells important both for drug screening and for applications in cell therapy for neuromuscular disorders.

NOVEL MARKERS OF HUMAN MIDBRAIN DOPAMINE NEURONS AS IDENTIFIED THROUGH BAC TRANSGENIC MOUSE EMBRYONIC STEM CELLS

Yosif M. Ganat
Developmental biology, MSKCC, New York, NY, United States

In this study we used 3 BAC transgenic mESC reporter lines representing distinct stages of midbrain dopamine (mDA) neuron development - Hes5::GFP (early), Nurr1::GFP (mid), and Pitx3::YFP (late). After two weeks of differentiation, FACS-purified cells were subjected to microarray analysis under two different paradigms: interline (i.e. Pitx3+ vs Hes5+) and intraline (i.e. Nurr1+ vs. Nurr1-). Gene ontology and in vivo experimentation lead to the identification of novel transcription factors and cell surface proteins which have been confirmed by independent groups. This both demonstrates the remarkable fate specificity of ESC-derived mDA neuron and outlines the sequential stage-specific reporter line paradigm for in vivo gene discovery. Finally, preliminary data indicate that two surface markers identified may be used for in vivo visualization of mDA neurons and the purification of hESC-derived mDA neurons.

SCALABLE PASSAGING OF HUMAN PLURIPOTENT STEM CELLS

Ying Nie, Patrick Walsh, Diana Clarke, Jon Rowley, Thomas Fellner
Lonza Walkersville, Inc., Walkersville, MD, United States

Human pluripotent stem cells (hPSCs) hold great promise for the development of cell replacement therapies. However, for this promise to be realized numerous challenges need to be overcome; one of which is production of clinical-grade cells in a cost-effective manner. A critical but commonly overlooked step is the subcultivation of the cells. Current methods used to subculture hPSCs are incompatible with clinical manufacturing processes because they are labor intensive and result in reduced cell viabilities. To improve on these methods, we set out to develop a cGMP-compliant, non-enzymatic passaging reagent that requires minimal manual manipulation of cells. This hypertonic sodium citrate-based solution promotes multicellular colony detachment and high post-detachment cell viability. Treatment of hESC cultures with this passaging solution results in a post-detachment cell viability of 97%. Comparatively, conventional methods such as colony scraping, Collagenase IV or Dispase treatment exhibit significantly lower cell viabilities of 27, 58 and 67% in StemPro® and 31%, 47% and 53% in mTeSR™1, respectively. The increase in viable cells achieved through the use of the hypertonic sodium citrate-based solution at each passage significantly reduces the time required to generate sufficient quantities of hPSCs for clinical-scale production. The total number of cells produced from a starting population of $2x10^5$ hPSCs utilizing this passaging process exceeds $2x10^{12}$ cells. We also demonstrated that hPSCs continuously sub-cultivated with the hypertonic citrate solution for over 25 passages retain a normal karyotype and co-express the classic subset of markers indicative of hPSC pluripotency: Oct4, SSEA4, Tra-1-60, Nanog and Tra-1-81. We believe this streamlined passaging process offers a new method suitable for the cultivation of high-quality hPSCs in the research laboratory and clinical manufacturing suite.

PATENTING LIFE, US SUPREME COURT'S DECISION ON GENE PATENTS AND ITS POTENTIAL IMPACTS ON STEM CELL RESEARCH

Maude L. Cuchiara, Kirstin RW Matthews
Baker Institute for Public Policy, Rice University, Houston, TX, United States

Patenting Life, US Supreme Court's Decision on Gene Patents and its Potential Impacts on Stem Cell Research
Kirstin RW Matthews* and Maude L Cuchiara*
*James A. Baker III Institute for Public Policy, Rice University
In 1980, the landmark case *Diamond v. Chakrabarty* guaranteed the ability to patent some forms of life. Researchers fought to patent a bacterium that had been genetically modified to digest oil, and ultimately, the court ruled that "anything under the sun made by man" was patentable. This decision led to the patenting of mice strains, human stem cells, and other living organisms or their components, including genes. In 1997 and 1998, Myriad Genetics was granted patents for two genes—BRCA1 and BRCA2—which are implicated in hereditary breast and ovarian cancer. Due to the patent, Myriad is currently the only company that can conduct diagnostic testing for these genes. The patenting of the BRCA genes launched a raucous debate about the ability to patent life: how do we distinguish between what is simply discovered and what is truly "made by man"?
The American Civil Liberties Union (ACLU) and the Association for Molecular Pathology challenged the gene patents, and the US Supreme Court selected the case for its 2013 docket. The court will rule on one of Myriad Genetics' claims: the patentability of human genes. The decision made in this case will affect the patentability of other biological "inventions" such as human embryonic stem cells (hESCs). In the US, hESC patents are almost exclusively held by the Wisconsin Alumni Research Fund (WARF). Many researchers in the field opposed these patents for a similar rationale as gene patent opponents: hESCs were discovered, not created or made. As a result, in 2006, the Foundation for Taxpayer and Consumer Rights and the Public Patent Foundation asked the US Patent and Trademark Office (USPTO) to revoke the patent. The USPTO ultimately validated the patents but limited their breadth and mandated a relaxation in licensing procedures. If the Supreme Court rules that gene patents are invalid, the ability to patent hESCs would likely be challenged and possibly revoked.
Here we will describe the progression of the Myriad Genetics case as well as compare the legal and scientific rationale for and against gene patents to that of hESC patents. We will then discuss the arguments made by both sides to the Supreme Court and speculate on how these arguments and each possible Supreme Court ruling (if a ruling has not been released) apply to the patenting of hESCs and surrounding technologies. We will also compare US and EU policies on similar technologies and elaborate on the problems associated with the judicial system ruling on regulations of highly scientific material. Finally, we will reflect on the appropriateness of these types of patents – comparing the BRCA gene and WARF stem cell patents.

W-2057

EXPANDING BIOLOGICAL PATHWAY MODELS WITH FUNCTIONAL GENOMICS DATA IMPROVES COMPUTATIONAL PATHWAY ANALYSIS OF STEM CELL DIFFERENTIATION

Daniel Carlin, Joshua Stuart
Biomolecular Engineering, University of California- Santa Cruz, Santa Cruz, CA, United States

The high throughput analysis of the transcriptome has become a central tool in stem cell biology. Although some important transcription factors have been elucidated, little is known about the pathways involved in differentiation from a systemic point of view. We have developed an integrated analysis method called PARADIGM for the inference of pathways activated in cancer from the analysis of genomics data sets. The method has successfully identified aberrant gene hubs in many tumor types including glioblastoma, ovarian, breast, and kidney cancer. To investigate stem cell processes, we have extended the pathway database utilized by PARADIGM by incorporating predicted interactions from the analysis of functional genomics datasets including ChIP-Seq, co-expression data across a large number of tissue types, conservation of binding sites, protein-protein interactions, and miR target predictions. The newly incorporated evidence is organized into "tiers" that reflect the amount of independent data sources support the existence of each interaction. By adding the highest tier of most supported interactions to our pathway database, we have been able to provide suggestions for novel gene interactions that are important in stem cell differentiation. We applied this new, expanded pathway database to the meta-analysis of publicly available stem cell datasets to provide a robust pathway view of commonly performed differentiation assays. Several of the active gene clusters are common to cancer pathways and suggest links between stemness and cancer, and give clues to the treatment of cancers. We also applied the expanded pathway database to a cortical neuron differentiation RNA-seq time course. By isolating the biological entities most active in the differentiation course, we are able to provide gene candidates for inducing and repressing cortical neural differentiation.

W-2058

ENDODERM DIFFERENTIATION OF HUMAN PLURIPOTENT STEM CELLS BY CELL PATTERNING.

Takuya Okazaki[1], Masakazu Machida[2], Ryo Tamoto[2], Yuichi Tanaka[1], Katsunori Tsuchiya[1], Yuji Shimizu[1], Hidenori Akutsu[2], Akihiro Umezawa[2]
[1]Life Science Laboratory, Dai Nippon Printing Co., Ltd., Tokyo, Japan, [2]Department of Reproductive Biology, National Center for Child Health and Development, Tokyo, Japan

Human pluripotent stem cells (hPSCs) have the potential to be used in many applications due to their ability to differentiate into cells of any of the three germ layers (ectoderm, endoderm, and mesoderm). When guiding differentiation, embryoid bodies are made in culture solution containing differentiation-inducing factors and subsequently maintained for a fixed period with adhesive cultivation. However, high efficiencient directed differentiation is technically challenging and currently a bottleneck in the field. Differentiation of hPSCs to a mature cell type typically requires serial cell culture steps with sequential addition of extrinsic factors including growth factors and cytokines. Testing a significant number of such differentiation protocols is therefore very labor intensive and time consuming and limits the development of optimized methods. In order to solve such problems, we have developed cell culture materials.
Generally, cells respond differently to substrates of varying stiffness of culture plates. In the current work, we set up several conditions of cell patterning using micro-fabrication technique and investigate the effect of microstructural features on the differentiation of hPSCs. Multiple gene expression analysis of cultured hPSCs on various diameter circle patterned substrates by qRT-PCR using a TaqMan Array revealed that smaller pattering induced endodermal markers expression including Afp, Foxa2, Gata6 and Isl1. This analysis reveals the sensitivity of cellular phenotype commitment and differentiation patterning responding microstructural features. It would be used to help guide the design of scaffolds with specific properties for tissue engineering applications using hPSCs.

W-2061

SYNTHEMAX II-SC, A NOVEL SYNTHETIC SURFACE FOR PLURIPOTENT STEM CELL CULTURE.

Zara K. Melkoumian, Jerry Zhou, David Henry, Paula Dolley-Sonneville, Jennifer Weber
Life Sciences Development, Corning Inc, Corning, NY, United States

Scalable, reproducible, low cost and regulatory-friendly technologies must be developed to enable clinical use of pluripotent stem cell (PSC)-based therapeutics. PSC culture methods use complex, animal-derived products, such as mouse feeder layers and mouse tumor extracts or human-derived biological substances to coat culture vessels. Most of these materials are costly, of limited scalability, have high batch to batch variability and are a potential source of adventitious agents. For clinical applications of PSC-based therapeutics it is highly desirable to have defined, scalable culture systems for production of cells suitable for clinical use.
In this study we describe a fully synthetic substrate, Synthemax II-SC, for the culture of PSCs. The substrate is comprised of an RGD-containing peptide sequence derived from the active domain of the vitronectin protein linked to an acrylate polymer. The surface coating protocol with Synthemax II-SC is very simple and consists of dissolving the powder substrate in water, dispensing and incubating in a culture vessel for 1-2 hours. Unlike biological coatings, Synthemax II-SC is very stable, and pre-coated vessels can be stored for up to 2 months.
We have demonstrated a multi-passage expansion of hiPSCs and hESCs on Synthemax II-SC coated plates in mTeSR1 defined medium. Importantly, cells maintained typical morphology, consistent doubling time, expression of pluripotency markers (Oct4 and SSEA4), normal karyotype and the potential to differentiate into cell types of all three germ layers after long-term culture on Synthemax II-SC coated plates.
In combination with defined medium, Synthemax II-SC provides a complete culture system for both research applications and scalable manufacturing of PSCs.

W-2062

PERFUSED MICROPLATE FOR CONTROLLED STEM CELLS DIFFERENTIATION

Kaitlyn Matias, Vasiliy Goral, Po Ki Yuen, Florence Verrier
Biochemical Technologies, Corning Inc, Corning, NY, United States

Human embryonic stem cells (hESCs) or human induced pluripotent stem cells (hiPSCs) hold great potential for cell therapy, drug efficacy research, toxicity screens and predictive disease modeling. This is mainly due to two distinct properties: (i) they can self-renew indefinitely and (ii) they can potentially generate all cell types in the human body. The challenge in using hESCs or progenitor stem cells for various applications has been to direct the wide differentiation potential toward the derivation of a specific cell fate. hESCs or progenitor neural stem cells can be differentiated *in vitro* into neural progenitor cells, neurons, oligodendrocytes and astrocytes. However, there is still a lack of efficient and robust protocols to obtain high percentage of differentiated neuronal cells that show good maturity and characteristics of *in vivo*-like functional cells.
Controlling the cell microenvironment has become crucial in the stem cell field where scientists are trying to differentiate or reprogram cells typically by overcoming these signals via adding their own exogenous factors. These exogenous factors are often added at saturating concentrations, blanketing the cells to activate specific pathways to produce a desired outcome (e.g. specific phenotype). However, the constant din of cell communications is still present, causing alternate and perhaps opposing pathways to be stimulated. This constant cell secretion in conventional static culture limits therefore the development of new methods to elicit a specific phenotype.
Here we describe a new method of culture (passively perfused cell culture) creating a dynamic microenvironment allowing better stem cell growth and stem cell differentiation relative to conventional static culture. Specifically, we demonstrated that passively perfused cell culture improved stem cell performance (increased growth rate) compared to conventional static stem cell culture, without altering their self-renewal property. We also demonstrated a substantive improvement of the differentiation of neural progenitor stem cells into astrocytes and neurons. This method of culture is also very attractive as it does not require any daily medium change, reducing substantially the labor of culture. Overall, the passively perfused microplate can be used for spatiotemporal control over the stem-cell microenvironment, so that the ideal *ex vivo* niche for cell survival or differentiation can be defined quantitatively and in high throughput.

W-2063

NON-BIASED COMPARATIVE ANALYSES OF PIGGYBAC, TOL2, AND SLEEPING BEAUTY TRANSPOSON SYSTEMS BY A NON-DRUG SELECTION PLATFORM IN HEK293

Yaa-Jyuhn James Meir, Sareina Chiung-Yuan Wu
Chang Gung University, Kwei-Shan, Taiwan

Three non-viral DNA transposon systems, *Tol2*, *piggyBac*, and *Sleeping Beauty*, have gained momentum as genetic tools for mammalian genome manipulations. Previous reports have provided guidance for choosing the most suitable transposon to meet individual experimental needs by comparing *piggyBac*, *Tol2, and Sleeping Beauty* in terms of their activity and genome-wide targeting profiles. However, all of these studies focused exclusively on transposon targeting events that result in transgene expression, and consequently under-represent practical situations encountered in fundamental and translational/clinical research where it is also necessary to analyze transposition events that result in transgene silencing.
In this study, we exploited a novel non-drug selection platform to gain a non-biased and more insightful comparison of the three transposon systems in HEK293 cells. We analyzed chromosomal targeting activity, transgene expression rate, and the genome-wide target profile of transposon-integrated clones with or without transgene expression. We found that the most favorable system to uncover genes that are involved in key differentiation processes but are epigenetically silenced at the time of targeting is *piggyBac*, due to the following characteristics: (1) its extremely high chromosomal targeting rate (~ 94%) in a drug-free setting, (2) its high transgene expression rate, (3) its ability to access inactive chromosomal regions, and (4) its preferential intragenic targeting. The first two characters along with its lowest transgene silenced rate and its unique amenability for molecular engineering to achieve site-specific therapeutic gene targeting make *piggyBac* the most promising transposon among these three for gene therapy.

ACTIVATED PLATELET SUPERNATANT CAN AUGMENTED THE ANGIOGENIC POTENTIAL OF PERIPHERAL BLOOD STEM CELLS IN STEM CELL THERAPY.

Jin-A Kang, Jin Hur, Ji-Yeon Yun, Jae-Il Choi, Young-Eun Choi, Ju-Young Kim, Jeehoon Kang, Ji-Hoon Hong, Jung-Kyu Han, Hyun-Jai Cho, Young-Bae Park, Hyo-Soo Kim
Seoul national university, Seoul, Korea, Republic of

Despite the progress in stem cell therapy, efficacy of tissue repair is still modest in ischemic diseases. Although platelets are known to play a role in hemostasis, they also promote angiogenesis by releasing various cytokines. We investigated the improvement of stem cell therapy, by priming granulocyte-colony stimulating factor (G-CSF) mobilized peripheral blood stem cells (mobPBSCs) with ‘activated platelet supernatants (APS)’.
Healthy volunteers underwent daily subcutaneous injections of G-CSF for 3 days, and mobPBSCs were isolated while APS was collected by thrombin activation of the platelet rich plasma. APS contained various cytokines such as IL-8, IL-17, PDGF and VEGF. APS-primed mobPBSCs increased expression of genes to support angiogenesis and mobPBSC differentiation was polarized toward CD14++/CD16+, so called pro-angiogenic monocytes, with an increase of cell surface integrins. To check the paracrine effect of APS-priming, primed mobPBSCs were cultured for 36 hours. The supernatants of APS-primed mobPBSCs could augment proliferation and formation of a capillary network formation in human umbilical vein endothelial cells. In vivo transplantation of APS-primed mobPBSCs into athymic mice ischemic limb and Matrigel plugs elicited enhanced vessel differentiation, which improved tissue repair. Safety analysis of APS primed mobPBSCs was proven by the increased platelet activity when primed mobPBSCs were mixed in whole blood, which was decreased when pretreated with aspirin.
Collectively, our data identify that APS priming can enhanced the angiogenic potential of mobPBSCs, which can be used as a novel method in increasing efficacy of stem cell therapy.

DISCOVERY OF A NOVEL PLURIPOTENCY MARKER BC2LCN USING LECTIN MICROARRAY

Hiroaki Tateno, Yasuko Onuma, Yuzuru Itou, Makoto Asashima, Jun Hirabayashi
AIST, Tsukuba, Japan

Induced pluripotent stem cells (iPSCs) can now be produced from various somatic cell (SC) lines by ectopic expression of the four transcription factors Oct4, Sox2, c-Myc, and Klf4. Although the procedure has demonstrated to induce global change in gene and microRNA expressions, and even epigenetic modifications, it remains largely unknown how this transcription factor-induced reprogramming affects the total glycan repertoire expressed on the cells. Here we performed comprehensive glycome analysis of a large set of hiPSCs (114 cell types) and hESCs (9 cell types) using lectin microarray. In unsupervised cluster analysis of the results obtained by lectin microarray, both undifferentiated iPSCs and ESCs were clustered as one large group. However, they were clearly separated from the group of differentiated SCs, while all of the four SCs had apparently distinct glycome profiles from one another. This observation demonstrates that SCs with originally distinct glycan profiles have acquired those similar to ESCs upon induction of pluripotency. Thirty-eight lectins discriminating between SCs and iPSCs/ESCs were statistically selected, and characteristic features of the pluripotent state were obtained at the level of the cellular glycome: these include increased α2-6sialylation, α1-2fucosylation, and type1 N-acetyllactosamine (LacNAc), while corresponding decrease in α2-3sialylation, type2 LacNAc, and highly-branched N-glycans was observed. The expression profiles of the relevant glycosyltransferase genes agreed well with the results obtained by lectin microarray. Through the analysis, we identified a lectin rBC2LCN binds only undifferentiated iPSCs/ESCs but never differentiated SCs. rBC2LCN worked as a specific probe for staining and sorting of iPSCs and ESCs. Even live colonies of iPSCs and ESCs could be visualized just by the addition of fluorescein-labeled rBC2LCN into cell culture media. No effect on the properties of iPSCs and ESCs by rBC2LCN could be confirmed by DNA microarray, indicating that rBC2LCN is a suitable probe for live cell monitoring of human pluripotent stem cells during cell culture. Cell surface glycoprotein ligands of rBC2LCN were also examined. Podocalyxin, a hyperglycosylated transmembrane protein, was found to be a predominant one. Furthermore, rBC2LCN exhibited significant affinity to a mucin-type O-glycan comprising an H type3 structure prepared from human 201B7 iPSCs, suggesting that H type3 is a novel pluripotency marker. rBC2LCN can be expressed at high levels in a soluble form in the cytoplasm of Escherichia coli (80 mg/L) and can be purified to homogeneity in a one-step sugar-immobilized affinity chromatography approach. Thus, rBC2LCN, unlike antibody, could serve as a novel type of detection reagent of pluripotent stem cells, which is cost-effective and easy to produce in a large amount.

NOVEL MACROCARRIERS FOR IMPROVED HUMAN PLURIPOTENT STEM CELL EXPANSION IN STIRRED TANK BIOREACTORS.

Brian M. Davis[1], Evelina R. Loghin[1], Andrew A. Burns[2], Reginald D. Smith[1], Scott M. Miller[2], Kenneth R. Conway[3], Martin J. Brown[1], David G. Gascoyne[2]

[A]Life Sciences and Diagnostics, [B]Nanostructures and Surfaces Laboratory, [C]High Energy Physics Laboratory, [1]GE Global Research, Niskayuna, NY, United States

A need for large scale pluripotent stem cell culture is emerging for applications in pluripotent stem cell banking (e.g., for induced pluripotent stem cells), commercial production of cells (e.g., GE's Cytiva™ cardiomyocytes), and cell expansion for clinical trials. Advances in feeder-free embryonic stem cell culture have enabled large scale cell expansion, which is conventionally performed in flasks, but maintenance of large numbers of flasks is labor intensive, space prohibitive and poses concerns that individual flasks may exhibit phenotypic drift. Therefore, new approaches for scaling up stem cell culture are required. The research presented here describes human embryonic stem cell expansion in stirred tank bioreactors using a novel macrocarrier developed at GE Global Research. Conventional microcarriers are 150 to 250 microns in diameter; in comparison, GE's proprietary macrocarriers are ~6 mm in diameter and support the growth of more than 150,000 human embryonic stem cells per carrier. The density of the macrocarrier material easily promotes their fluidization with the generation of minimal shear forces under stir conditions, and rapid sedimentation in the absence of agitation. Four embryonic stem cell lines (CHB10 [from Dr. George Daley, Children's Hospital Boston], CT2 [from University of Connecticut Health Center], and H1 and H7 [both from Geron Corp.]) were expanded on GE's macrocarriers. The carriers were coated with different matrices that support embryonic stem cell attachment and growth including Matrigel™, Laminin 521 and Synthemax II™.

Cells were seeded onto to the macrocarriers in stirred tank bioreactors and expanded for 3 to 5 days prior to enzymatic passaging. The large size of the macrocarriers facilitated the gentle separation of cells from carriers during enzymatic cell recovery. The human embryonic stem cells exhibited similar doubling times when cultured on macrocarriers in stirred tank bioreactors as when cultured in 6-well plates and were morphologically similar to colonies grown in static culture. All four embryronic stem cell lines were maintained for 10 or more serial passages on GE's macrocarriers in stirred tank bioreactors. At the conclusion of macrocarrier culture, cells were analyzed for the pluripotency markers Oct4 and SSEA4, karyotype, embryoid body and teratoma formation. Cells recovered from the macrocarriers and replated onto 6 well plates retained cell morphology and expansion rates equivalent to the parental cells. Comparison cultures grown on commercial microcarriers (Cytodex 1^{TM}, Microhex^{TM} and Hillex II^{TM}) exhibited carrier-to-carrier bridging resulting in large clusters, three-dimensional colony growth, and reduced cell viability and recovery. In conclusion, four hESC cell lines were successfully expanded for 10 or more passages on novel shear protected macrocarriers while maintaining pluripotency in stirred tank bioreactors. This novel macrocarrier design solves many of the challenges that occur when culturing pluripotent cells on traditional microcarriers by providing shear projection, allowing easy separation of the carriers from cells during passaging, and preventing the formation of cell-carrier aggregates.

AN EFFECTIVE VERIFICATION OF ANTIFREEZE POLYAMINO-ACID FOR A SLOW CRYOPRESERVATION OF HUMAN IPS CELL AND ES CELL

AKEMI OTA[1], Kazuaki Matsumura[3], Hirofumi Suemori[2], Shoichiro Sumi[1], Suong-Hyu Hyon[4]
[A]Department of Organ Reconstruction, Field of Clinical Application, [B]Department of Embryonic Stem Cell Research, [1]Institute for Frontier Medical, Kyoto University, Kyoto, Japan, [2]Department of Materials Science New Materials Design and Synthesis, School of Materials Science, Japan Advanced Institute of Science and Technology, Nomi, Japan, [3]Center for Fiber and Textile Science, Kyoto Institute of Technology, Kyoto, Japan

[Objective] The cryopreservation of human iPS cells using slow-freezing after the single-cell passaging is better than that using vitrification of aggregated cells of dissected colonies, because huge volume of iPS cells is necessary for the clinical application. Furthermore, the single-cell passaging enables the differentiation experiment or the gene transfer into iPS cells easier than that of aggregated cells on feeder layer. Dimethyl sulfoxide (DMSO) is a superior cryoprotective agent, but it should be decreased as possible because of its higher cytotoxicity. In this study we developed the cryopreservation solution using carboxylated ε-poly-L-lysine (COOH-PLL), and investigated its effectivity after freezing for one month.
[Method] The cryopreservation solution was contained 3%COOH-PLL, recombinant human albumin and DMSO, whose concentration decreased as possible in DMEM/F12 medium. Single cell suspension of human iPS cells in the cryopreservation solution was stored at -80^{O}C for one month. After thawing the iPS cells and ES cells were cultured on the matrigel-coated plate with SNL-conditioned medium containing bFGF for four passages, and then tested for proliferation ability and multipotency.
[Results] Human iPS cells and ES cells were cultured in good adherence. The cell growth and multipotency were kept after four passages. The cryopreservation solution with 1% or 2% COOH-PLL decreased total colony numbers at AP staining. The concentration of DMSO was able to be decreased down to 6%. Adding the rock inhibitor, Y-27632, to the cryopreservation solution showed little effect for cryopreservation.
[Conclusion] We investigated the ability of cryopreservation solution using COOH-PLL at the stock period of one month and showed its effectivity. This solution is xeno-free and enough to be used for the clinical application. To the goal of future research, this cryopreservation solution will be developed for longer and huge storage.

W-2074

NANOCRYSTAL TRACKING OF A SLOW CYCLING STEM-LIKE SUBPOPULATION IN HUMAN ENDOMETRIUM

Lina N. Xiang, **Rachel W.S Chan**, Ernest H.Y Ng, William S.B Yeung

Obstetrics & Gynaecology, University of Hong Kong, Hong Kong, Hong Kong

Introduction: Human endometrium displays cyclical regeneration and tissue breakdown throughout a woman's reproductive life. Putative stem cells within the mucosal lining have been shown to be responsible for the remarkable regenerative capacity. A key feature of somatic stem cell is their quiescent state. However it remains unclear whether slow cycling cells exist in human endometrium. The objective of this study was to establish a novel in vitro stem cell assay employing nanoparticle tracking to isolate putative slow-cycling cells in endometrial stromal cultures.
Methods: Single human endometrial stromal cells obtained from women undergoing hysterectomy were labeled with fluorescent nanocrystals followed by a chase of 21 days in culture. Two population of stromal cells: slow-cycling (fluorescent persistent cell; FPC) and rapidly proliferating (non-fluorescent persistent cells; non-FPC) cells were isolated using fluorescent activator cell sorter. The stem cell properties of FPC and non-FPC were compared through the use of colony forming assay, serial subcloning, total cell output and in vitro differentiation assay. Molecular characterization of the two populations was assessed using real-time polymerase chain reaction with pluripotent (NANOG, OCT-4, SOX-2) and self-renewal (BMI-1) genes. The phenotypic expression of endometrial mesenchymal markers (CD146/CD140b, W5C5) on FPC and non-FPC was also examined using flow cytometry.
Results: Maximum fluorescent labeling of endometrial stromal cells (100%) was achieved 24 hours after primary cell culture. A minority (0.90 ± 0.09%, n=19) of FPC possessed the nanocrystals after long term culture (day 21). Assessment of stem cell characteristics revealed stromal FPC displayed a significantly higher colony forming ability and underwent more rounds of self-renewal than non-FPC. The multipotency of stromal FPC to differentiate into the mesenchymal lineages upon exposure to adipogenic, osteogenic, myogenic and chondrogenic induction media was significantly higher than non-FPC. Clonally derived FPC expressed mRNA of pluripotent and self-renewal (NANOG, OCT-4, SOX-2, and BMI-1) genes. Furthermore, there was significantly higher percentage of cells within the FPC population expressing of endometrial mesenchymal stromal cell markers (CD146+/CD140b+ or W5C5+).
Conclusion: We have established a novel in vitro endometrial stem cell assay in which putative slow cycling human endometrial stromal cells can be identified through nanoparticle tracking. Using this assay, we demonstrated that FPC share common somatic stem cells properties, in particular that of mesenchymal origin.

BIOREACTOR-BASED EXPANSION OF MESENCHYMAL STEM CELLS ON NOVEL SHEAR-PROTECTED CARRIERS

Vandana Keskar[1], Joanne F. Smith[1], Reginald Donovan Smith[1], Zhipeng Zhang[2], Andrew A. Burns[3], Scott Michael Miller[4], Martin James Brown[1], David Gilles Gascoyne[3]
[A]Life Sciences & Diagnostics, [B]Machines Laboratory, [C]Nanostructures and Surfaces Laboratory, [D]Engineered Materials, Chemistry & Physics, [1]GE Global Research, Niskayuna, NY, United States

Mesenchymal stem cells (MSCs) are being researched for multiple therapeutic applications due to their immunomodulatory properties and tri-lineage differentiation potential. Clinical trials target MSCs for cell therapy and regenerative medicine applications such as graft versus host disease, critical limb ischemia, acute myocardial infarction and osteoarthritis. High cell doses (up to 5 MM cells/kg body weight) necessitate fast and reproducible *in vitro* MSC expansion techniques. Adherent cell expansion is often carried out on planar static formats. These methods involve handling of many pieces of cultureware, clean rooms and multiple manual operations which are inefficient and increase the risk of contamination. Bioreactors with microcarriers have the potential to address the above concerns for adherent cell expansion. However, cell numbers generated through these techniques are less than satisfactory due to the challenges in growing shear sensitive MSCs in fluidized carrier systems. Other challenges with traditional microcarriers for MSC expansion are difficulty in visualizing cells on the carriers, ease of harvest and cell separation from the microcarriers.
To address the above concerns and provide a novel platform for adherent cell expansion in bioreactors we developed polystyrene(PS)-based macro-carriers. The 6mm hexagonal carriers are made of plasma-treated, medical grade polystyrene and provides cells with a growth surface chemically similar to T-flasks. Relief features on the

carriers provide shear protection to the adherent cells thus enabling use of the carriers in bioreactors. The carrier density and size are designed to enable easy fluidization in dynamic conditions. Multiple lots of commercially available bone marrow-derived MSCs (p2) were successfully expanded on the PS carriers in spinner flasks. Initial cell attachment on the carriers in dynamic conditions was similar to attachment on static T-flasks. The expansion protocol was optimized for impeller rpm, agitation on/off times and feed schedules to obtain T-flasks comparable cell densities at harvest. The doubling times for MSCs grown in the spinner flasks was also comparable to static T-flask controls. No additional surface coatings were required to support cell growth in serum-based medium. For serum-free culture of MSCs, the carriers were pre-coated with cell-attachment matrices with the same protocols as for T-flasks. Unlike most commercial microcarriers where aggregation of the carriers is observed at high cell densities, no aggregation of the polystyrene carriers was observed even at cell densities of 30,000 cells/cm^2. The native spindle-shaped morphology of cells grown on the carriers could be viewed under the brightfield microscope. Cell separation from the carriers at harvest was complete with >95% viability using traditional enzymatic dissociation technique and did not necessitate use of cell filters or any additional cell separation equipment due to the large size of the carriers relative to the cells. The MSCs harvested post bioreactor expansion retained their tri-lineage differentiation potential and cell surface markers (CD105+, CD90+ & CD73+). This novel carrier based bioreactor system has the potential to enable MSC expansion in a closed, automated and scalable manner thus reducing labor and contamination risks associated with static planar cultures.

REDUCING MICROBIAL CONTAMINATION IN STEM CELL CULTURE THROUGH H2O2 DECONTAMINATION TECHNOLOGY - INCREASED EFFICIENCY AND EFFICACY WITH SIGNIFICANTLY REDUCED DOWNTIME FOR STEM CELL CULTURE

Deepak M. Mistry[1], Nehal Kothari[2], Kondala Atkuri[3]

[A]Marketing & Strategic Development, [B]Marketing & Strategic Application, [1]Panasonic Healthcare Company of North America, Wood Dale, IL, United States, [2]Genetics, Stanford University, Stanford, CA, United States

The most common form of contamination in stem cell products for cell therapy and regenerative medicine are Bacteria (including *Mycoplasma*), yeast and fungi. Recent studies have found that Mycoplasma contamination rate in these stem cell products was between 4% to as high as 22% with overall cell culture contamination of up to 12% or even higher in some cases. Of all the likely sources, the cell culture incubator has often been considered one of the most probable sources of biological contamination. Many incubator manufacturers have addressed this issue using different types of sterilization technologies. A study was undertaken to determine the effectiveness and efficiency of three industry-leading incubators that utilize different sterilization techniques: Brand P with the H_2O_2 decontamination technology that requires 2 hours for its cycle with around 15 minutes of prep time, Brand A with a dry heat sterilization method that takes 10-12 hours for the complete process, and Brand B with a moist heat sterilization method that requires up to 25 hours from start to finish. Five different microorganisms, generally considered the most common contaminants in a cell culture environment, were tested in this study: *Candida albicans, Acholeplasma laidlawii, Mycoplasma orale, Bacillus subtilis, and Staphylococcus aureus*. At a specific CFU, each organism was placed on both upper and lower shelves of the incubators, which were then allowed to go through their individual sterilization cycle. A time control coupon was also run simultaneously for the same amount of time as the sterilization cycle. Each of the three cell culture incubators showed complete bioburden reduction for each organism. However, the H_2O_2 decontamination technology offered complete organism elimination in 2 hours, as compared to 10-12 hours and 25 hours for Dry heat and Moist heat sterilization technology, respectively. In addition, a significant reduction in viability was observed for *Candida albicans, Acholeplasma laidlawii and Mycoplasma orale,* when each time control was compared. The H_2O_2 decontamination technology effectively showed a greater bioburden reduction than the heat sterilization techniques, when the 2-hour time control was compared to the 10-12 hour and 25 hour time controls. This validates the effectiveness with which the H_2O_2 technology decontaminates the chamber. For *Staphylococcus aureus and Bacillus subtilis*, an increase in viability was observed over time

when compared to time controls. However, the H_2O_2 decontamination technology efficiently eliminated all of the bioburden in a considerably shorter span of time without significantly increasing the original concentration of the organisms. The 2-hour uptime advantage offered by the H_2O_2 decontamination technology with 100 % kill rate and at least a 6 log reduction for all the organisms tested, lead to increased productivity in a research or GMP environment.

Human embryonic stem cells (hESCs) have been proposed as a promising candidate for tissue regenerative therapies to cure various diseases, including nerve, heart liver, and pancreas. Therefore, intensive studies have been carried out to screen effective and cost-beneficial inducing agents including growth factors, cytokines, and extracellular matrices to differentiate hESCs into a special linage of somatic cells. In general, physical extracellular microenvironment provides crucial inducing factors to stem cells themselves and surrounding extracellular substrates. In this study, we describe a direct, simple, and effective differentiation of hESCs into definitive endodermal cells using only a nanopore pattern chip without any growth factors and cytokines. hESCs were dissociated into single cells and grown on the nanopore pattern chip (pore size; 200nm) in RPMI medium in the absence of any growth factors. Real-time PCR, immunochemistry, and proteome array data showed that the nanopore pattern chip significantly increased endodermal differentiation of hESC. Compared to conventional culture dishes, the number of SOX17-positive cells was significantly increased by differentiating hESC on the nanopore pattern (approximately 2-fold, $P<0.05$). The SOX17-positive cells coexpressed CXCR4 as well as FOXA2, which are typical markers of the definitive endoderm. Expression of endoderm-associated proteins was increased by growing on the nanopattern chip. Consequently, the nanopore pattern chip developed in this study could be a new effective and cost-beneficial tool for the endodermal differentiation of hESCs.

Whole-cell mass spectrometry profiling combined with artificial intelligence as a novel tool for fingerprinting of hESCs

Petr Vaňhara[1], Lukáš Kučera[1], Filipo Amato[2], Eladia María Peña-Méndez[3], Milan Ešner[1], Josef Havel[2], Ales Hampl[1]

[A]Department of Histology and Embryology, [B]Department of Chemistry, [1]Masaryk University, Brno, Czech Republic, [2]Department of Analytical Chemistry, Nutrition and Food Science, University of La Laguna, La Laguna, Spain

There is an ongoing need for a robust, feasible and sensitive method for determining cell identity and/or revealing possible phenotype perturbations. The molecular, genetic and/or light-microscopy analyses fail in case of small and subtle but critical changes arising in cultured cells. General bio-analytical methods, e.g. matrix-assisted laser desorption/ionization - time of flight mass spectrometry (MALDI-TOF MS) have manifold applications in classical analytical and structural chemistry. Due to its inherent principal universality, this method became attractive beyond

chemistry and has been adapted also for characterization of complex biological samples. However, mass spectra generated from ionized molecules desorbed from the whole cells are rather complex and usually reflect not only the biological variability but also variety of other factors, e.g. experimental conditions. Artificial neural networks (ANNs) represent a non-linear mathematical model resembling a brain neural architecture and possessing "learning" and "generalization" abilities. Such sophisticated mathematical analysis reduces unwanted inconstancy and can identify hidden patterns in mass spectra.
As a proof of the principle, we first aimed to discriminate between biologically distinct cell types, human embryonic cells (hESCs) and mouse embryonic fibroblasts (MEFs). The hESCs and MEFs were cultured under standard conditions, harvested by scraping, washed in inorganic buffers and mixed with acidified matrix without corruption of cellular integrity. Several organic matrices as well as sample deposition methods were tested. The MALDI-TOF MS was then performed in several mass ranges, with varying detector mode and laser power. The mass spectra reached high-level of reproducibility in the range of approx. 6000-16000 m/z, equivalent to molecular weight approx. 6-16 kDa. We were able to identify sample specific peaks and to perform cluster/factor analysis. Despite the successful classification of all analyzed samples, the factor analysis does not allow to perform nonlinear clustering of samples. Using ANNs we were able to compensate for nonlinearities in complex data (e.g. biological and instrumental variability). The robust database of whole-cell mass spectra was build and served as input for feed-forward neural network. After training of the ANN, we achieved 100% discrimination between hESCs and MEFs. We then tested whether this approach can discriminate between morphologically uniform, yet innerly different hESCs. The hESCs were stimulated with 0,1µM retinoic acid (RA) for only 10 hours or left untreated and then processed with whole-cell MALDI-TOF MS. The correctly trained ANNs were able to reach significantly high level of discrimination while the cluster and factor analysis did not identify differences. In summary, we developed and optimized a simple, robust and efficient cell authentication tool enabling routine use in clinical grade cell cultures.

A NONINVASIVE METHOD FOR COUNTING HUMAN PLURIPOTENT STEM CELL NUMBERS BY LIVE CELL IMAGING

Mika Suga[1], Hiroaki Kii[2], Takayuki Uozumi[2], Yasujiro Kiyota[2], Miho K. Furue[1]
[1]Dept of Disease Bioresources Research, Laboratory of Stem Cell Cultures, National Inst of Biomedical Innovation, Osaka, Japan, [2]Instruments company, NIKON CORPORATION, Yokohama, Japan

Background: Cell density is a critical factor for control both growth and differentiation of human pluripotent stem (PS) cells including embryonic stem (ES) cells and induced pluripotent stem (iPS) cells. Despite the fact of the evolution of human PS cell culture techniques, counting cell numbers is still problematic. Therefore, we have developed a noninvasive cell counting method for human PS cells through analyzing live cell images.
Methods: H9 (WA09) human ES cells were cultured and then stained with a cell-permeant SYTO24 green fluorescent nucleic acid stain (Invitrogen). Phase contrast and fluorescent images of H9 were obtained during culture in a cell incubator observation system, BioStation CT (Nikon Corporation) and analyzed by a software CL-Quant (Nikon Corporation). Area of H9 colony coverage was measured from phase contrast images. Number of stained nuclei was counted from green fluorescent images. Immediately after imaging, the conventional cell counting by hemocytometer was performed for comparison.
Results: The nucleus counting and the conventional cell counting showed similar results. In the case total numbers of cells were above 1×10^4, cell numbers by nucleus counting were similar and reproducible with those by conventional cell counting. There was a significant correlation between the colony coverage area and the nucleus/cell counting. These results show that numbers of human PS cells can be estimated from the total colony coverage area through phase contrast imaging.

Conclusions: Thus we have developed a new noninvasive cell counting method. Furthermore, obtaining time-lapse phase contrast images enables us to monitor colony morphological changes and to calculate growth rate during human PS cell culture. Our noninvasive technique is useful for consistent seeding of human PS cells and high-throughput screening analysis of cell numbers, proliferation, and growth curves.

VIRTUAL KARYOTYPING OF STEM CELLS BASED ON THEIR GLOBAL GENE EXPRESSION PROFILES

Uri Ben-David[1], Yoav Mayshar[2], Nissim Benvenisty[1]
[1]Hebrew Univ Stem Cell Unit, Jerusalem, Israel, [2]Dept. of Genetics, Harvard Medical School, Boston, MA, United States

The genomic instability of stem cells in culture, caused by their routine in-vitro propagation or by their genetic manipulation, is deleterious both for their clinical application and for their use in basic research. Frequent evaluation of the genomic integrity of stem cells is thus required, and is usually performed using cytogenetic or DNA-based methods, at variable sensitivities, resolutions and costs. These methods require access to the cells - or at least to DNA from the cells - and their application is usually limited to cell lines one has readily at hand. In contrast, gene expression microarrays have become a common tool in stem cell research and microarray data are frequently deposited in public databases.
Here we present a method that enables the accurate evaluation of the genomic integrity of stem cells based on their gene expression data. Once gene expression microarrays are generated from the cell lines of interest, they are compared to a database of similar gene expression profiles using two complementary bioinformatic analyses. The results obtained from these analyses are then combined to faithfully determine what genomic aberrations are present in the examined samples. This expression-based karyotyping method (which we termed "e-karyotyping") was initially validated by analyzing human embryonic stem cells (hESCs) with known chromosomal aberrations. We then e-karyotyped a large data set of human ESCs and conducted the first large-scale analysis of genomic integrity in human induced pluripotent stem cells (hiPSCs). Recently, we also applied e-karyotyping to mouse and rhesus PSCs, demonstrating that it is not restricted to human cells. Lastly, we also performed e-karyotyping to examine the genetic stability of human adult stem cells, namely hematopoietic stem/progenitor cells (HSPCs), neural stem cells (NSCs) and mesenchymal stem cells (MSCs), demonstrating that each stem cell type is prone to acquire a unique set of chromosomal aberrations, and that these aberrations are similar to those observed in tumors of the same cell lineage.
The current work provides a detailed protocol for using global gene expression profiles to determine the genomic integrity of stem cells, with an emphasis on PSCs. This e-karyotyping protocol describes how to properly organize gene expression microarray data, how to subject it to two complementary bioinformatic analyses, and how to interpret the results in a conservative manner, in order to generate an accurate estimation of the chromosomal aberrations in the autosomal genome of examined stem cell lines. This is an easy-to-follow protocol that every standard laboratory in the field will be able to adopt and implement.

FUNCTIONAL HETEROGENEITY OF UMBILICAL CORD BLOOD CD34 POSITIVE CELLS

Elena Afrimzon[1], Naomi Zurgil[1], Yana Shafran[1], Maria Sobolev[1], Ronit Goldman-Levi[2], Eilat Shinar[3], Mordechai Deutsch[1]

[1]Physics, Bar-Ilan University, Ramat Gan, Israel, [A]Public Cord Blood Bank Lab, [2]Magen David Adom, Ramat Gan, Israel

Background. The great heterogeneity in living cells provides the stable spatiotemporal function of the multicellular organism. UCB contains hematopoietic stem cell pools belonging simultaneously to both adult/mother and embryo/infantorganisms. Study of morphological and functional heterogeneity in the CD34 positive UCB cells at the single cell level may provide sufficiently detailed information which can contribute to the understanding of the biological activity of these cells and their potential use.

Methods. In this study, we present an imaging approach based on the cell retainer methodology for real-time investigation of the functional intracellular characteristics of UCB cells. This methodology enables repetitive, high-content correlative multi-parametric measurement and image analysis of individual cells within a population, during various manipulations, e.g. drug introduction, staining procedures, etc. [Deutsch M. et al, 2006]. Fresh UCB units from healthy newborns were obtained

from Magen David Adom Public Cord Blood Bank (Israel). Initially, red blood cells were sedimented using dextran and thereafter mononuclear cells were isolated using Ficoll-Hypaque. The separated mononuclear cells were loaded into the *LiveCell™ Array* and a panel of vital tests was performed at the level of individual cells. For instance, cell death rate (PI staining), cytoplasm membrane integrity and intracellular metabolism (the rate of fluorescein-diacetate hydrolysis by non-specific esterases calculated from repeated periodic measurements for each single cell), mitochondrial membrane potential (TMRM staining) and Heochst dye (HD) efflux. UCB mononuclear cells were sorted based on their CD34 fluorescence intensity (FI). The functional features of CD34 positive

versus negative cells, as well as the difference between subfractions of $CD34^{highFI}$ and $CD34^{low\ FI}$ cells were analyzed.

Results and Conclusions. On average, 8.8±3.7% of the total mononuclear cells exhibited positive staining with anti-CD34 antibodies. Living CD34 positive cells demonstrated significantly lower (p<0.001) MMP (TMRM dye FI) and significantly higher (p<0.02) HD FI in comparison to CD34 negative cells. In contrast, the intracellular non-specific esterases demonstrated a similar rate of FDA hydrolysis in CD34 positive and negative cells. Among CD34 positive cells ~30% exhibited high FI signal, while the rest had a low FI signal. The $CD34^{high\ FI}$ fraction did not efflux HD effectively, in contrast to $CD34^{low\ FI}$ cells which are associated with significantly lower staining (p<0.03). On the other hand, these two fractions of CD34 positive cells do not differ significantly with respect to MMP and ability to hydrolyze FDA.

Thus, freshly isolated CD34 positive mononuclear cells derived from UCB reveal a certain level of heterogeneity with respect to intracellular functional characteristics. The results obtained may be important for further basic investigations, and to applied research as well.

W-2094

BENEFICIAL EFFECT OF PAN-CASPASE INHIBITOR FOR CRYOPRESERVATION OF HUMAN UMBILICAL CORD DERIVED MESENCHYMAL STEM CELLS (HUC-MSCS)

Back Soo Shin, Su-Youne Han, Hyun Woo Lee, Jin Tac Kim, Hyeon Kyeong Lee, Seung Hoon Pak, Ji Hyang Kim, Byung-Rok Do

Biotechnology Research Institute, Hurim BioCell Inc., Seoul, Korea, Republic of

The cryopreservation of hUC-MSCs has become an important process for the therapeutic protocol, which includes stem cell transplantation. In the conventional cryopreservation protocol, using the high concentration of dimethylsulfoxide (DMSO) presented various cytotoxic effects for stem cell. Therefore, to reduce the cytotoxicity of DMSO, we studied the roles of non-permeable cryoprotective agents (Np-CPAs; pan-caspase inhibitor, antioxidant and disaccharide) for effective cryopreservation.

hUC-MSCs were cryopreserved with Group 1) 10% DMSO and 20% serum substitute supplement (SSS) as a control, Group 2) 5% DMSO and 5% SSS, Group 3) 5% DMSO and 5% SSS treated with 0.1M sucrose, 0.1M trehalose, 1mM antioxidant (1mM Glutamine) and 5% pan-caspase inhibitor (5% N-benzyloxycabonyl-Val-Ala-Asp-fluoro-

methylketone; zVAD-fmk), respectively. The relative survival rates of frozen-thawed cells were measured by trypan blue staining after 2 weeks of storage in a LN_2 tank. The population growth rate and doubling time of cultured cells were assessed using the MesenPRO medium for 5 weeks.
The relative survival rate was 76.74% (group1) of conventional cryopreservation protocol. And it was 70.38% (group2) of 5% DMSO, showed reduced relative survival rate than group1. Additional effect of 0.1M sucrose, 0.1M trehalose and 1mM glutamine (group3), showed similar relative survival rate compared with the control (group1), but it was increased relative survival rate than group2. The treatment with 5% zVAD-fmk (group3), showed a significantly higher relative survival rate (91.65%) than without it (group1 and group2) (p;0.027, p;0.026). The population growth rate and doubling time of cultured cells were showing similar results between w and w/o Np-CPAs.
These results were presented that the reduced concentration of DMSO by supplement of Np-CPAs, especially caspase inhibitor has an advantage to overcome the many side effects of cryopreservation in cell therapy.

Multiple system atrophy (MSA) is a neurodegenerative disorder of primarily glial origin. Clinically it is distinct from Parkinson's disease with predominantly autonomic failure and motor impairment. The motor symptoms generally respond poorly to dopaminergic therapy. Pathologically, the principal cellular targets are oligodendrocytes that show abundant glial cytoplasmic inclusion bodies consisting of alpha-synuclein aggregates and nigrostriatal degeneration. Protein misfolding and aggregation of alpha-synuclein is a common feature across synucleinopathies and an attractive target for drug development.
In order to study the contribution of α-synuclein to the disease phenotype of MSA, we generated induced pluripotent stem cells (iPSCs) from a patient with MSA and then created isogenic lines with SNCA deletional mutations using the transcription activation-like effector nucleases (TALEN) technology. We designed two sets of TALENs to create deletions in exon 2 of the SNCA gene in patient derived iPSCs via non-homologous end-joining (NHEJ). After functional verification of the SNCA TALENs carried out in HEK cells and confirmed with the Surveyor assay and sequencing, iPSCs from the MSA patient were edited with SNCA TALENs. Colonies that showed positive cuts in the Surveyor assay were picked and expanded. These colonies were further characterized by sequencing on the Ion Torrent PGM instrument to identify clonal populations with SNCA deletional mutations. We then differentiated both the edited lines and isogenic control iPSC line into neural stem cells and glial cells for functional characterization. In conclusion, TALEN technology can be applied to generate isogenic disease iPSCs for studying the contribution of SNCA in the disease phenotype of MSA.

CHARACTERIZATION OF IPSC-DERIVED NEURONS CONTAINING A FAMILIAL ALZHEIMER'S DISEASE MUTATION

Shahad Rahawi[1], Grace Woodruff[2], Lawrence S. B. Goldstein[2]
[1]San Diego State University, San Diego, CA, United States, [2]University of California, San Diego, La Jolla, CA, United States

Alzheimer's disease (AD) is the leading cause of dementia worldwide, and AD cases are estimated to increase three-fold by 2050 due to an aging population. The pathological hallmarks seen in AD brains include amyloid-β (Aβ) plaques, neurofibrillary tangles of hyper-phosphorylated tau protein, synaptic loss, and neuronal death. Sequential proteolysis of amyloid precursor protein (APP) by beta and gamma secretases generates Aβ fragments, which are

the main constituents of the senile plaques. The majority of AD cases are sporadic, without a known genetic or environmental cause. However, there is a small subset of patients with dominantly inherited forms of the disease caused by mutations in APP and presenilin 1 and 2. IPSC technology allows us to capture the genomes of individuals with familial AD mutations and to differentiate iPSCs to neurons and glia to study the mechanisms that cause AD. Here we report the characterization of iPSC-derived neurons from cell lines containing the familial AD mutation, APP V717F. We report that the APP V717F mutation increases the Aβ42/40 ratio in purified neurons and increases APP β c-terminal fragments (βCTFs). Studying how an increased Aβ42/40 ratio and increased APP βCTFs contribute to AD will be vital for future therapeutic intervention.

W-2103

TALEN-MEDIATED INTRODUCTION OF APP SWEDISH AND MV POINT MUTATIONS IN AN IPSC MODEL OF FAMILIAL ALZHEIMER'S DISEASE

Nina D. Kloss, Sol M. Reyna, Lawrence S. Goldstein
Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA, United States

Alzheimer's Disease (AD) is a progressive and to-date irreversible neurodegenerative disease that presently affects more than 26 million people worldwide. This number is predicted to greatly increase by the year 2050. While more than 95% of AD cases occur sporadically without a known genetic cause, mutations in the amyloid precursor protein (APP) or presenilin genes (PS1 and PS2) have been attributed to rare autosomal dominant forms of familial AD (FAD). In this context, the Swedish mutation was identified as a genetic variation leading to FAD. This mutation alters the processing of APP by enhancing beta-secretase cleavage which leads to increased generation of both APP C-terminal fragments and pathogenic amyloid-β (Aβ) peptide. In contrast, the MV mutation has a single point mutation at the same site to inhibit beta-secretase cleavage. We are generating transcription activator-like effector nucleases (TALENs) to introduce these Swedish and MV point mutations in Craig Venter's cell line. TAL effectors are proteins secreted by plant pathogenic bacteria and bind to DNA in a modular fashion allowing for precise DNA targeting. The generation of isogenic iPSCs containing Swedish and MV mutations will provide the tools necessary to address the contribution of different APP fragments (namely APP CTFs and Aβ peptides) in driving axonal transport defects of organelles and vesicles, such as lysosomes and mitochondria.

ABETA 42 TO 40 RATIOS IN HUMAN NEURONAL CULTURES ARE RESISTANT TO PHARMACOLOGICALLY RELEVANT CONCENTRATIONS OF GAMMA SECRETASE MODULATORS

Philipp Koch[1], Jerome Mertens[1], Kathrin Stüber[1], Patrick Wunderlich[2], Julia Ladewig[1], Rik Vandenberghe[3], Mathieu Vandenbulcke[4], Philip van Damme[3], Jochen Walter[2], Oliver Brüstle[1]
[A]Reconstructive Neurobiology, [B]Neurology, [1]University of Bonn, Bonn, Germany, [A]Neurology, [B]Psychiatry, [2]University Hospitals Leuven, Leuven, Belgium

Altered production, accumulation and aggregation of amyloid beta peptides (Aβ) in the brain are hallmarks of sporadic and familial Alzheimer's disease (AD). As increasing evidence suggests that elevated fractions of the highly amyloidogenic Aβ42 variant are causative in AD pathogenesis, γ-secretase modulators (GSM) that selectively lower Aβ42 emerged as potential therapeutic agents. Surprisingly and despite promising preclinical data, the GSMs so far tested in human clinical trials proved inefficient in delaying disease progression. While the reasons for these failures remain obscure, it is striking that most data on the potency of GSMs have not been generated in bona fide human neurons. The advent of human pluripotent cells (hPSC) has enabled the generation of human neurons in large quantities. Here we show that neurons derived from human embryonic stem cells (hESC) and induced pluripotent stem cells (iPSC) endogenously generate Aβ and that familial AD patient-specific iPSC-derived neurons exhibit an elevated Aβ42/40 ratio. However, exposure to GSMs at concentrations that can be clinically achieved in the brain and that were efficient in non-human cell models did not alter the ratio of Aβ42/40 in these neurons. Thus, our

data reveal an unexpectedly low responsiveness of authentic human neurons to pharmacological γ-secretase modulation, which might explain the observed clinical failure of GSMs.

W-2105

IN VITRO MODELING OF ALZHEMER'S DISEASE

Maya Mitalipova[1], Julien Muffat[1], Yun Li[1], Tenzin Lungjangwa[1], Ping Xu[1], Robert Moir[2], Doo Yeon Kim[2], Rudolf Tanzi[2], Rudolf Jaenisch[1]

[1]Whitehead Institute for Biomedical Research MIT, Cambridge, MA, United States, [2]Genetic and Aging Research Unit, Massachusetts General Hospital, Harvard Medical School, Charlestown, MA, United States

Alzheimer's disease (AD) is characterized by progressive dementia and brain deposits of the amyloid β protein (Aβ) as senile plaques and the microtubule-associated protein, Tau, as neurofibrillary tangles (NFT). Recent developments in induced pluripotent stem cells (iPSCs) derivation have allowed investigation of phenotypes of neurological diseases in vitro, and provide opportunities to generate human cell-based models that will be crucial for drug discovery, as well as to investigate disease mechanism.
We have generated iPS cells from patients with familial AD (FAD type 3), from a Canadian family with A246E mutation in the presenilin 1 (PS1) protein, and from non-demented kins. We transduced fibroblasts with doxycycline (dox) inducible, single Cre-excisable lentiviral vector encoding four reprogramming factors (Oct4, Sox2, Klf4 and c-Myc) flanked by lox-P sites as a polycistronic cassette. These cells also were transduced with a constitutive Cre-excisable lentiviral vector expressing M2rtTA. Patient and control iPS cells were, using SMAD signaling inhibition (dorsomorphin), differentiated to highly expandable neural progenitors and matured into the neuronal and glial phenotypes relevant to AD. This induced rapid and complete neural conversion of iPS cells under adherent culture conditions. In particular, we have generated glutamatergic excitatory neurons and astrocytes from each patient. To evaluate their usefulness as an AD model we measured the levels of Abeta-40 and Abeta-42 secreted from 8-10 weeks old neurons by sandwich ELISA. We show that total Aβ secretion is much higher in neuroglial cultures, making these a far better model to study the disease than fibroblasts. Then we compared the ratio of Abeta-42 to Abeta-40 to total Abeta secreted by control and mutant neurons. Mutant neurons showed higher ratio of Abeta-42/40 compare to control neurons. To determine whether soluble or non-soluble Abeta species are neurotoxic in vitro, and assess whether sub-types of neurons are selectively vulnerable we exposed control cells to varying concentrations of stressors, including pre-aggregated Aβ42 and soluble Aβ extract from supernatants from A246E human neurons. Toxicity assessment has been performed in parallel, using a vital dye (PrestoBlue), as well as endpoint immunohistological staining of neuronal dendrites (MAP2), astrocytes (GFAP) and mature synapses (Synapsin puncta). We have found that mutant neurons have less complex dendritic arbors and are more vulnerable to Abeta-42 s compare to control neurons.
In conclusion we describe phenotypic changes of human AD neurons in vitro, which will allow us to investigate the mechanism of the disease and effect of small molecules to rescue the AD phenotype.

W-2106

USING HUMAN INDUCED PLURIPOTENT STEM CELL DERIVED MOTOR NEURONS TO ELUCIDATE THE ROLE OF MUTANT SOD1 IN MITOCHONDRIAL DYSFUNCTION AND TRANSPORT IN AMYOTROPHIC LATERAL SCLEROSIS

Theodore Peng[1], Evangelos Kiskinis[2], Steve Han[3], Kevin Eggan[1]

[A]Human Developmental and Regenerative Biology, [B]Molecular and Cellular Biology, [1]Harvard University, Cambridge, MA, United States, [2]Department of Neurology, Massachusetts General Hospital, Boston, MA, United States

Induced pluripotent stem cells (iPSCs) offer a new and exciting approach to disease modeling. Given the fact that they are patient specific (i.e. with identical genomes to the patients from which they are derived), iPSCs possess the ability to accurately replicate the phenotype of certain diseases. Our lab has created various iPSC lines from patients with familial cases of Amyotrophic Lateral Sclerosis (ALS), and has differentiated these lines into lower motor

neurons, the cell type affected in ALS. Mutations in Cu/Zn superoxide dismutase 1 (SOD1) are some of the most common causes of familial ALS, and the resulting mutant SOD1 protein is often found localized to the surface of mitochondria in motor neurons. This phenotype is found in conjunction with alterations in morphology, localization, and transport of mitochondria along the axons of motor neurons in SOD1 mutant mouse models. Furthermore, there have been reports of perturbations in calcium homeostasis and apoptosis activation of mitochondria. However, these observations have been made using non-human or non-motor neuron systems that overexpress mutant SOD1 protein, or human post mortem biopsies that offer only end-stage time points of the disease. In order to address these issues, we have used our iPSC-derived motor neuron in vitro model to elucidate the mechanisms and pathways underlying mitochondrial dysfunction, and to understand the influence mitochondria have on the ALS phenotype.

W-2107

A NOVEL CELL MODEL SYSTEM FOR STUDYING MECHANISMS OF SOD1-ASSOCIATED AMYOTROPHIC LATERAL SCLEROSIS.

Ilya Chestkov[1], Ekaterina Vasilieva[1], Ekaterina Khomyakova[1], Sergey Illarioshkin[2], Maria Lagarkova[1], Sergey Kiselev[1]

[1]Department of Epigenetics, Vavilov Institute of General Genetics, Russian Academy of Science, Moscow, Russian Federation, [2]Research Center of Neurology, Russian Academy of Medical Science, Moscow, Russian Federation

Amyotrophic lateral sclerosis (ALS) is a fatal disorder of motor neuron degeneration with unclear mechanisms and no effective treatment to date. The most commonly occurring mutations in patients with familial ALS (FALS) are found in the Cu, Zn superoxide dismutase (SOD1) gene and account for approximately 20% of all FALS. It is assumed that misfolded mutant SOD1 protein can be selectively toxic to motor neurons and therefore most cases of classic ALS can be considered as a conformational disorder. One of the most promising approaches to understand the primary causes of the disease is to generate a cell model system based on patient-specific induced pluripotent stem cells (iPSC). We have obtained and characterized human motor neurons with three different SOD1 mutations through differentiation of iPSCs derived from patients affected by SOD1-associated ALS. These motor neurons could be specifically visualized during differentiation process and sorted due to Hb9::eGFP-IRES-Puro motor neuron-specific reporter cassette introduced in each iPSC line. The resulting model system will allow using motor neurons in the co-cultivation experiments with other cell types (non-cell autonomous effect), and also test whether neuron death in ALS can be a cell autonomous process as well.

W-2108

ALS PATIENTS' MOTOR NEURONS EXHIBIT PREFERENTIAL IMPAIRMENT IN NEUROFILAMENT AND MITOCHONDRIAL DYNAMICS IN ABSENCE OF GLIA

Hong Chen, Kun Qian, Zhongwei Du, Jinagyuan Cao, Lisle W Blackbourn IV, Anthony Errigo, Cindy Huang, Melvin Ayala, Ling Yao, Su-chun Zhang
Waisman center, Madison, WI, United States

Amyotrophic lateral sclerosis (ALS) is characterized by presence of neurofilament tangles in cell bodies and axons followed by degeneration of motor neurons. The cause and underlying mechanisms of neurofilament aggregation and preferential motor neuron vulnerability remain unknown. Mutations in the Cu/Zn Superoxide Dismutase (SOD1) gene are associated with 20% familial forms of amyotrophic lateral sclerosis (ALS) and transgenic expression of multiple copies of the mutant forms of human SOD1 in animals indeed leads to neuronal degeneration. To gain insights into the process of motor neuron degeneration in ALS patients and to build a dynamic model for dissecting disease pathogenesis and for drug discovery, we established induced pluripotent cells (iPSCs) from patients with SOD1 mutations. Analysis of the iPSC-derived neurons indicated that the ALS hallmark pathology, neurofilament aggregation, appeared progressively in spinal motor neurons but rarely in non-motor neurons before glial cells have

developed in the system. The neurofilament aggregates were associated with deficits in mitochondrial function as well as transportation along axons. Expression of a single copy of the same mutant SOD1 in human embryonic stem cells (ESCs) by TALEN-mediated transgenesis resulted in the same pathological changes in motor neurons but not non-motor neurons that are differentiated from the transgenic hESCs. Genetic correction of the SOD1 mutation in the patient's iPSCs by TALEN-based homogeneous recombination prevented the above pathological phenotypes. These results indicate that the SOD1 mutations lead to structural and functional degeneration, preferentially in motor neurons and that the degenerative process occurs in a cell-autonomous manner. They also suggest the usefulness of the iPSC strategy for modeling the pathological process of ALS. Studies are under way to dissect out early events that lead to neurofilament and mitochondrial changes, to understand the preferential vulnerability of motor neurons, and to build platforms for drug discovery.

APPLYING IPSC MODEL TO STUDY P53 MUTATION ASSOCIATED CANCER DISSEASE

Jie Su[1], Dung-Fang Lee[1], Betty Chang[1], Julian Gingold[1], Henia Darr[1], Carlos-Filipe Pereira[1], Avinash Waghray[1], Ran Brosh[1], Christoph Schaniel[1], Razmik Mirzayans[2], Ihor R. Lemischka[1]

[1]Department of Developmental and Regenerative Biology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, [2]Department of Oncology, University of Alberta, Edmonton, AB, Canada

Embryonic stem cells (ESCs) hold enormous promise for biomedicine. In vitro modeling of human disease has recently become possible due to induced pluripotent stem cell (iPSC) methodologies. Characterized by their ability to self-renew indefinitely and differentiate into all cell lineages of an organism like ESCs, iPSCs provide a powerful and unlimited source of cells to generate differentiated cells that can be used to elucidate disease pathogenesis, for drug discovery and development, toxicology screening, personalized healthcare and eventually cell transplantation-based therapies. Here, we apply iPSC technology to investigate p53 mutation-associated cancer disease. This will create a "disease in a dish" platform to elucidate the underlying pathogenesis caused by these p53 mutations.
We obtained fibroblasts from a family with heterozygous Gly245Asp (G245D) mutation in the TP53 gene. We have generated integration-free iPS cell lines from three patients and two unaffected family members by Sendai virus (SeV)-based delivery of the 4 Yamanaka reprogramming factors, OCT4, SOX2, KLF4 and c-MYC. These iPS clones express hESC pluripotency factors NANOG, OCT4 and SOX2, hESC surface markers (TRA-1-81 and SSEA4), and alkaline phosphatase (AP). iPS lines were tested for loss of Sendai virus by PCR. The G245D mutations in SeV-free iPSC lines have been confirmed in 3 patients and wild-type status confirmed in 2 related family members. The iPSC lines were further characterized to verify normal karyotype, expression of NANOG, OCT4 and SOX2 pluripotency markers at levels comparable to hESCs and reduced OCT4 promoter methylation compared with original fibroblasts. In order to obtain a comprehensive picture, we will further identify genome-wide differences between WT and mutant p53 (G245D) lines by transcriptome, miRNAs, interactome and ChIP-seq approaches. Integrating these data will provide insights into the tumor suppressor role of p53. Collectively, applying iPSC technology to study cancer disease will provide an invaluable avenue to unravel the tumor-promoting role of p53 mutants.

W-2112

MODELING IDIOPATHIC AUTISM USING INDUCED PLURIPOTENT STEM CELLS

Maria Carolina Marchetto[1], Patricia Beltrão-Braga[2], Haim Belinson[3], Yanelli Nunez[1], Karen Pierce[4], Eric Courchesne[4], Antony Wynshaw-Boris[3], Alysson Muotri[5], Fred Gage[1]

[1]Salk Institute, La Jolla, CA, United States, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]University of California San Francisco, San Francisco, CA, United States, [A]Autism Center of Excellence, [4]University of California San Diego, La Jolla, CA, United States

Autism spectrum disorders (ASD) are complex neurodevelopmental diseases that affect about 1% of children in the United States. Such disorders are characterized by deficits in verbal communication, impaired social interaction, as

well as limited and repetitive interests and behavior. The precise mechanisms that cause autism, however, remain unknown. Recently, neuropathological imaging and genetic studies have provided important insights into ASD, and these studies have led to two major hypotheses for autism pathogenesis: altered brain growth and dysfunctional neuronal networks (Courchesne et al. 2003; Dementieva et al. 2005; Garber 2007). The major impediment to testing these and other hypotheses of autism is the lack of relevant animal and cell models. The direct study of live brain tissue from ASD patients is unfeasible, and no suitable animal models can adequately reproduce the complicated structure and function of the human brain to study social behavior and language acquisition. Recently, reprogramming of human somatic cells to a pluripotent state by over-expression of specific genes into induced pluripotent stem cells, or iPSCs (Takahashi et al., 2007) has provided an exciting opportunity to produce a relevant human cellular model of human complex neurogenetic diseases, and iPSCs have been generated for several neurological disorders and diseases, including Rett syndrome, a syndromic ASD (Marchetto et al. 2010). Here we show the generation of 8 idiopathic autistic iPSC lines and 5 age/gender-matched control lines. We also performed differentiation into neural progenitor cells (NPC) and mature neurons in culture. We are now revealing cellular phenotypes that can directly test the two current models for autism pathogenesis abovementioned (cell proliferation, cell migration and proper neuronal maturation). Knowledge of whether altered brain growth and/or dysfunctional neuronal networks play a role in the development of autism will inform studies in human patients. These studies should provide important and novel insights into the development of ASD and will test whether cellular markers are present in patient-derived NPCs and neurons from iPSCs. Knowledge of the biological causes of neural maldevelopment in ASD would likely lead to the development of clinically useful biomarkers of risk for this disorder in young, pre-symptomatic infants, which may lead to the development of novel therapies.

W-2113

IN VITRO MODELING OF NIEMANN-PICK TYPE C DISEASE USING PATIENT-SPECIFIC INDUCED PLURIPOTENT STEM CELLS

Dorothea Maetzel[1], Haoyi Wang[1], Sovan Sarker[1], Lina Abi Mosleh[2], Qing Gao[1], Maisam Mitalipova[1], Rudolf Jaenisch[1]

[1]Whitehead Inst for Biomedical Research, MIT, Cambridge, MA, United States, [2]Department of Molecular Genetics, University of Texas Southwestern Medical Center, Dallas, TX, United States

Patient-specific induced pluripotent stem (iPS) cells derived from somatic tissues provide a unique tool to study human diseases *in vitro*. The potential of iPS cells to generate unlimited quantities of disease affected cell types make them a realistic source for the analysis of disease underlying mechanisms, small molecule drug screening and autologous transplantation. Therefore patient specific iPS cells are potentially useful to develop new strategies to treat patients suffering from various degenerative diseases.
Niemann-Pick disease type C (NPC1) is an inherited, progressive neurodegenerative lipid storage disorder caused by mutations in the NPC1 or NPC2 gene. Mutations in these genes result in an accumulation of unesterified cholesterol in the late endosomes / lysosomes (LE/L) and an impairment of the cholesterol export from the LE/L to the endoplasmic reticulum (ER). The first clinical symptoms are often hepatosplenomegaly and cholestasis. The course of the disease is dramatic and subsequently leads to the death of the patient.
In the presented study we have generated vector-free iPS cells from patients suffering of NPC1 disease. Using different biochemical approaches we were able to evaluate and identify disease-related phenotypes in different cell types including cells of the neuronal and hepatic lineage. We have, using transcription activator-like effector nucleases (TALENs) mediated gene editing, generated isogenic NPC1 and control iPS cell lines and are investigating the effect of NPC1 deficiency on disease relevant phenotypes in neuronal and hepatocyte-like cells.

W-2114

MODELING DISEASE SEVERITY IN AN IPSC-BASED IN VITRO MODEL OF FAMILIAL DYSAUTONOMIA

Nadja Zeltner[1], Gabsang Lee[2], Faranak Fatahi[3], Fabien Lafaille[4], Jason Tchieu[1], Lorenz Studer[1]

[1]Developmental Biology/Center for Stem Cell Biology, Memorial Sloan-Kettering Cancer Center, New York, NY, United States, [2]Institute for Cell Engineering, John's Hopkins University, Baltimore, MD, United States, [3]Graduate School, Cornell University, New York, NY, United States, [4]St. Giles Laboratory of Human Genetics of Infectious Diseases, Rockefeller University, New York, NY, United States

Pluripotent stem cells have the potential to become any cell of the body and a key goal in disease modeling studies is to utilize cells of interest to understand the pathology associated with the disease. Familial Dysautonomia (FD) is a neurodegenerative/neurodevelopmental genetic disease that we employ to establish the principle of in vitro disease modeling as a valid alternative/addition to animal models of human diseases. Thus, offering the possibility to study disease specifics, accomplish drug screening and drug testing. Using FD-patient derived cells, we have previously shown that FD can be successfully modeled by using the induced pluripotent stem cell (iPSC) technology. iPSCs were generated from FD patients and differentiated into neural crest precursors (the cells specifically affected in FD). Three disease characteristics of FD were reproduced in vitro in neural crest precursors indicating that FD can be modeled effectively. However, FD patients display a range of symptoms, from severe and mild (both homozygous) to the asymptomatic, heterozygous carrier phenotype. We aim to investigate if this range of severity can be reproduced using our iPSC-based disease model and determine the mechanism behind differences in disease severity.
Using iPSCs from FD patients with severe, mild, absent (heterozygous) and healthy control patients, we differentiated them into neural crest progenitor cells and examined their in vitro phenotype. Aside from the FD-specific mis-splicing of IKBKAP, there is no difference between severe and mild patients in neural crest progenitors, suggesting no difference in the ability to generate the early neural crest lineage. However, the generation of Mash1-positive autonomic precursor cells is greatly affected in cells derived from severe patients, while cells from mild patients can generate equal numbers of autonomic precursor cells compared to controls. This suggests a specific defect in autonomic neurogenesis in severe but not mild patients, leading us to hypothesize that severe patients have both a neurodevelopmental and neurodegenerative defect, while mild patients may only have a neurodegenerative defect. To further test this hypothesis we are addressing the neurodegenerative aspect of the disease in more detail. To this end, we are employing our recently established differentiation protocols to generate peripheral sensory neurons, cells specifically affected by degeneration in FD patients. Survival capacities are being studied in these cells comparing sensory neurons derived from severe, mild or control FD patients.

IDENTIFICATION OF NOVEL TARGETS USING PSEN1 FAMILIAL ALZHEIMER'S DISEASE HIPSC-DERIVED NEURAL PROGENITORS

Andrew A. Sproul[1], Samson Jacob[1], Deborah Pre[2], Soong Ho Kim[3], Michael W. Nestor[1], Matthew Zimmer[1], Soline Aubrey[2], David J. Kahler[1], John F. Crary[2], Ottavio Arancio[2], Sam Gandy[3], Scott A. Noggle[1]
[1]The New York Stem Cell Foundation, New York, NY, United States, [2]Pathology & Cell Biology and the Taub Institute for Research on Alzheimer's Disease, Columbia University, New York, NY, United States, [3]Neurology and Psychiatry and the Alzheimer's Disease Research Center, Icahn School of Medicine at Mount Sinai, New York, NY, United States

The most prevalent theory for the underlying cause of Alzheimer disease (AD) is the "amyloid hypothesis", in which toxic oligomerogenic forms of Abeta, a cleavage product of APP, accumulate and cause neuronal dysfunction and cell death. Presenilin 1 (PSEN1) encodes the catalytic subunit of γ-secretase, and PSEN1 mutations are the most common cause of early onset familial Alzheimer's disease (FAD). FAD mouse models and human AD pathology suggest potential deficits in adult neurogenesis and newborn neuron survival, indicating a potential important role for NPCs in the disease. In addition, the brains of early-onset Alzheimer's patients might have developmental alterations that could affect disease initiation. Thus, we interrogated potential difference in human FAD IPSC-derived NPCs, which have not been studied to date. We furthermore asked whether PSEN1 NPCs, a more homogenous population than the wide spectrum of mature neurons produced by a general neuronal differentiation, could be used to identify novel molecules potentially important for early events in AD. We generated induced pluripotent stem

cells (iPSCs) from affected and unaffected individuals from two families carrying PSEN1 mutations, the “Canadian” (FAD1, A246E PSEN1 mutation) and the “Italian” (FAD4, M146L PSEN1 mutation) FAD kindreds. iPSCs were characterized using a variety of quality-control assays, and eight iPSC lines were selected to serve as a core set for the majority of our experiments We successfully differentiated iPSCs into NPCs and electrophysiologically-active neurons, and PSEN1 NPCs have a small neurogenic advantage over control NPCs. PSEN1 mutant fibroblasts and NPCs produced greater ratios of Abeta42 to Abeta40 relative to their control counterparts, with the elevated ratio even more apparent in PSEN1 NPCs than in fibroblasts. Molecular profiling identified 14 genes differentially regulated in PSEN1 NPCs relative to control NPCs. We confirmed these hits in brains from common, sporadic AD cases with advanced or intermediate pathology by qPCR and by comparison to published transcriptomes of laser captured microdissected (LCM) cortical neurons from brains with AD pathology. Five of these targets showed differential expression in late onset AD/Intermediate AD pathology brains. Several of our gene hits have potential roles in human CNS development. Therefore, in our PSEN1 iPSC model, we have reconstituted an essential feature in the molecular pathogenesis of FAD, increased generation of Abeta42/Abeta40, and identified potential new therapeutic targets.

W-2116

INVESTIGATION OF PRION-LIKE PROPAGATION OF TAU USING NEURONS DERIVED FROM IPSCS

Patrick C. Reilly[1], Shauna Yuan[2]

[1]San Diego State University, San Diego, CA, United States, [2]Neurosciences, University California San Diego, La Jolla, CA, United States

Alzheimer’s disease is a neurodegenerative disorder affecting 5.4 million people nationwide and is the sixth leading cause of death in America. Lack of any treatment for this disease has caused death rates to rise while advancements in treatment for other leading causes of death in the United States have resulted in a statistically significant decrease in death rates. Progress in the treatment of Alzheimer’s disease has been inhibited by an insufficient understanding of disease pathology. Human and murine models for investigation exist, but Alzheimer’s disease is a human specific disease and acquiring neuronal cell lines from patients is difficult, expensive, and in short supply. Given the circumstances, there is a clear necessity for an easily accessible system which allows for the study of disease pathology and drug treatment in a human cell model. Our use of induced pluripotent stem cell (iPSC) derived neurons with mutations commonly found in individuals with Familial Alzheimer’s Disease (FAD) provides a unique, in vitro - human cell model for pathological investigation of Neurofibrillary Tangles (NFT), aggregates of misfolded tau protein, and Amyloid-β (Aβ) plaques, both of which play a significant pathological role in Alzheimer’s disease. Murine in vivo investigations of NFTs have demonstrated prion-like propagation of tau aggregates through anatomically connected nervous tissue. Consistent with disease progression, NFTs are associated with deafferentation and eventual neurodegeneration via propagation through neural networks. Recent work has shown both axonal and dendritic bulk-endocytotic uptake of aggregates, but the specific species, toxic processes, and mechanism of release into cellular cytosol and extracellular space remain largely unknown. Using iPSC derived neurons with FAD defects; we explore tau pathology by comparing diseased lines to wild type (WT) controls via transformed expression of a fluorescently labeled, tau aggregate promoting plasmid. Preliminary data confirms mutant tau plasmid induced aggregation in HEK 293T cells. Furthering this work through mutant tau plasmid transformation of iPSC derived neurons, we expect to see different cellular responses between WT and FAD cell lines to the tau aggregates. We anticipate the use of iPSC derived FAD and WT neurons as an in-vitro cell model will provide new insights in Alzheimer’s disease pathology and treatment.

W-2117

DISEASE-SPECIFIC INDUCED PLURIPOTENT STEM CELLS AS A USEFUL STEM CELL MODEL FOR HUNTINGTON’S DISEASE

Kyung-Ah Choi

Department of Biomedical Science, College of Health Science, Korea University, Seoul, Korea, Republic of

Huntington's disease (HD) is a neurodegenerative disorder caused by an expansion of CAG tri-nucleotide repeats that results in neuronal dysfunction and death. Neuronal death occurs in many brain regions, while degeneration of DARPP-32$^+$ GABAergic neurons in the striatum underlies motor dysfunction in HD. Recently, several groups have already reported the efficient differentiation of DARPP-32$^+$ GABAergic neurons from human embryonic stem cells (hESCs) and human induced pluripotent stem cells (hiPSCs) of normal and HD patient fibroblasts. In this study, we showed that normal and HD iPSC lines were successfully established and characterized from normal and HD patient fibroblasts carrying an expanded CAG triplet-repeat tract, respectively. In our experiments to confirm pluripotency of normal and HD iPSCs using RT-PCR and immunocytochemistry, the expression of various pluripotent marker genes and proteins, such as OCT4, SOX2, C-myc, Klf4, Nanog, SSEA4, and TRA-1-60, was similar to those of hESCs. In our *in vitro* differentiation experiments, the normal and HD iPSC lines were differentiated into the DARPP-32$^+$ GABAergic neurons using MS5 stromal feeder cells (MS5) and culture media containing various cytokines and small molecules. The hiPSCs were differentiated into striatal GABAergic neurons, which were stained with various markers DARPP-32, GABA, GAD65/67, and βIII-tubulin. The normal hiPSCs were differentiated into approximately 87 % βIII-tubulin$^+$ (Tuj1$^+$) neurons out of total cells, and were 86% GABA$^+$ out of Tuj1$^+$ cells. The HD iPSCs were differentiated into approximately 85% Tuj1$^+$ neurons out of total cells, and were 81% GABA$^+$ out of Tuj1$^+$ cells. Interestingly, however, we found distinct expression patterns of various GABAergic markers between normal and disease hiPSCs in our RT-PCR experiments. Taken together, these results suggest that the pathogenesis of HD may be implicated to different expression of key genes, and that our HD iPSC lines could be provided as useful stem cell models to study the pathological mechanisms of HD and to screen the drug for HD disease treatments.

W-2118

HUMAN INDUCED PLURIPOTENT STEM CELLS FOR CELL REPLACEMENT THERAPY IN HUNTINGTON'S DISEASE.

Narawadee Choompoo, Ngoc-Nga Vinh, Claire Kelly, Anne E. Rosser
BRG, School of Biosciences, Cardiff University, Cardiff, United Kingdom

Huntington's disease (HD) is a neurodegenerative condition caused by a mutation in the huntingtin gene (HTT). The extended CAG repeat ultimately leads to loss of medium spiny neurons (MSNs) in the striatum of the HD brain. Cell replacement therapy using primary human fetal tissue has shown 'proof of principle' as a strategy to treat this genetically inherited disease[1]. However, alternative cell sources need to be identified to overcome the ethical and logistical issues that are associated with using human fetuses. Induced pluripotent stem (iPS) cells were first introduced by Yamanaka in 2006 by direct reprogramming of fibroblasts to ES-like cells by using four defined factors (Oct4, Sox2, Klf4, c-Myc)[2]. This landmark discovery paves the way to produce an unlimited cell source behaving similarly to an ES cell. Human iPS cells have certain advantages for clinical application in that they overcome some of the ethical issue associated with hES cell derivation, and may overcome immune rejection by opening the way for autologous transplantation. Here we attempt to generate iPS cells suitable for safe clinical use by introducing reprogramming factors using the *piggyBac* Transposon[3,4] transduction system to human fetal fibroblasts and fetal neural stem (FNS) cells. Fetal cells may be more readily reprogrammed to a pluripotent state and may retain "epigenetic memories" pertaining to their cells of origin, thus rendering them more ready to differentiate back to that cell subtype. The generation of cells that are differentiated to precisely the same subtype lost in a specific condition is critical for functional benefit following transplantation of those cells into the brain. In this study, we have derived iPS cell lines from human fetal whole ganglionic eminence (the putative striatum) and recently validated their pluripotentcy and differentiation potential. To date, we have determined the pluripotential nature of one iPS cell line using a range of measures, including a genetic profile. The established iPS cell line has properties similar to human embryonic stem (ES) cells in morphology, surface antigen, and proliferation. We are applying a strategy for removal of the transduction vector into the established primary iPS cell line to generate vector-free iPS cells to directly differentiate into neural progenitor cells and ultimately MSNs-like cells by using published protocols, and continue
to generate iPS cells from a variety of cell sources.

JMJD3 NEGATIVELY REGULATES REPROGRAMMING THROUGH HISTONE DEMETHYLASE ACTIVITY DEPENDENT AND INDEPENDENT PATHWAYS

WEI ZHAO[1], Qingtian Li[1], Stephen Ayers[2], Yifeng Gu[1], Yidong Chen[3], Helen Yicheng Wang[1], Rongfu Wang[1]
[A]The Center for Inflammation and Epigenetics, [B]Genomic Medicine, [1]The Methodist Hospital Research Institute, Houston, TX, United States, [2]Department of Epidemiology and Biostatistics and Greehey Children's Cancer Research Institute, The University of Texas Health Science Center at San Antonio, San Antonio, TX, United States

Although somatic cell reprogramming to generate inducible pluripotent stem cells (iPSCs) is associated with profound epigenetic changes, the roles and mechanisms of epigenetic factors in this process remain poorly understood. Here we identify Jmjd3 as a potent negative regulator of reprogramming. Jmjd3-deficient MEFs produced significantly more iPSC colonies than did wild-type cells, while ectopic expression of Jmjd3 markedly inhibited reprogramming. We show that the inhibitory effects of Jmjd3 are produced through both histone demethylase-dependent and -independent pathways. The latter pathway is entirely novel and involves Jmjd3 targeting of PHF20 for ubiquitination and degradation via recruitment of an E3 ligase, Trim26. Importantly, PHF20-deficient MEFs could not be converted to fully reprogrammed iPSCs, even with knockdown of Jmjd3, Ink4a or p21, indicating that this protein exerts predominant effects on reprogramming. Our findings demonstrate a previously unrecognized role of Jmjd3 in cellular reprogramming and provide molecular insight into the mechanisms by which the Jmjd3-PHF20 axis controls this process.

ELUCIDATING REPROGRAMMING OF HUMAN FIBROBLASTS TO INDUCED PLURIPOTENT STEM CELLS (iPSCs)

Eriona Hysolli[1], Yoshiaki Tanaka[1], Xinghua Pan[1], Kun-Yong Kim[1], Michael Snyder[2], Sherman Weissman[1], In-Hyun Park[1]
[1]Yale University, New Haven, CT, United States, [2]Stanford University, Stanford, CA, United States

Reprogramming generates induced pluripotent stem cells (iPSCs), which are similar to embryonic stem cells (ESCs) and possess the features of self-renewal and pluripotency. iPSCs offer great opportunities for the biomedical sciences. They can be used as sources of autologous cell therapy, in vitro cellular models, and drug screening. The successful use of iPSCs largely depends on the thorough understanding of the reprogramming process. Reprogramming human somatic cells requires a long time, and yields a very heterogeneous population of cells which may not be easily identified as bona-fide iPSCs. Thus, understanding how reprogramming occurs is critical to generate iPSCs safely applicable in therapy. We have reprogrammed human primary fibroblasts to iPSCs using four reprogramming factors (OCT4, SOX2, KLF4, and c-MYC). At weeks 1, 2, 3, and 4, we FACS sorted populations of cells using a combination of cell surface markers (CD13, SSEA4, TRA160), and silencing of GFP-carrying four factor retrovirus. We obtained around 1,000 - 20,000 cells for each sample, which were subsequently amplified and sequenced using RNA-Seq technology.

OCT4 INDUCES PLURIPOTENCY THROUGH THE MODULATION OF ASH2L-MEDIATED HISTONE 3 LYSINE 4 METHYLATION

Bing Liao, Junjie Gu, Ying Jin
Shanghai Jiao Tong University School of Medicine, Shanghai, China

Reprogramming somatic cells
into induced pluripotent stem cells (iPSCs) using defined factors represents a
groundbreaking achievement for stem cell research and regenerative medicine. However,

the efficiency of iPSC generation, particularly when using genome insertion-free protocols, is very low, representing one of the major obstacles to the therapeutic application of reprogrammed cells. Elucidation of the mechanisms underlying induced pluripotency is important for the improvement of reprogramming efficiency. Experimental evidence indicates that expression of the 4 reprogramming factors (Oct4, Sox2, c-Myc and Klf4) at an optimal stoichiometry is critical for efficient reprogramming, and that the Oct4 dosage is a key parameter. Previous studies in our laboratory demonstrated that Wwp2, a HECT-type E3 ubiquitin ligase, specifically mediates Oct4 ubiquitination and represses transcriptional activity of Oct4. Furthermore, our results indicate that Wwp2-catalyzed ubiquitinated Oct4 proteins are subject to degradation by 26S proteasomes during the differentiation process of pluripotent stem cells. In this study, we identified 5 lysine residues on Oct4 as ubiquitin-conjugation sites using mass spectrometry. Mutation of the 5 lysine residues abrogated Wwp2-catalyzed Oct4 ubiquitin modification and enhanced the protein stability of Oct4 in differentiated cells. Based upon these results, we hypothesized that Oct4 defective in ubiquitin modification by Wwp2 might give rise to a higher reprogramming efficiency than wild type Oct4. To test the hypothesis, mutant Oct4 (Oct4-5R, the 5 lysine residues were mutated to 5 arginine) or wild-type Oct4 (Oct4-WT) was introduced into MEF (mouse embryonic fibroblasts) cells together with Sox2 and Klf4. Intriguingly, the Oct4-5R containing cocktail led to a reprogramming efficiency 10 times higher than that of the cocktail containing Oct4-WT. Consistently, Wwp2 null MEF cells had a significantly higher efficiency in pluripotency induction than wild type MEF cells, suggesting that Wwp2-mediated Oct4 ubiquitination represses pluripotency induction in MEF cells, probably through down-regulating the level of ectopically expressed Oct4 proteins. However, further investigation showed that the enhancement in the protein stability of the Oct4-5R mutant could not entirely account for its ability to improve the generation of iPSCs. Instead, we found that the higher pluripotency induction efficiency elicited by Oct4-5R could be attributed to the enhancement of Ash2l-mediated histone 3 lysine 4 methylation. Therefore, this study not only opens a new way to improve iPSC generation but also sheds light on the reprogramming mechanisms involving Oct4. Moreover, our results reveal how the reprogramming factor coordinates with the epigenetic regulator to control the induction of pluripotency.

W-2124

REACTIVATION OF X CHROMOSOME DURING HUMAN SOMATIC CELL REPROGRAMMING

Kun-yong Kim
Yale university, New haven, CT, United States

Induced pluripotent stem cells (iPSCs) are generated by reprogramming somatic cells with four transcription factors (Oct4, Sox2, Klf4, and c-Myc). Reprogramming causes fibroblasts to acquire an ESC-like epigenetic state, which includes expression of non-coding RNA, DNA and histone modification, and changes in X chromosome status. In recent studies, human female iPSCs with one active X chromosome or two active X chromosomes were found, suggesting that retention and reactivation of inactive fibroblast X chromosome could occur during reprogramming. X chromosome status in human female iPSCs in very important for future applications in in vitro and in vivo studies, but when and how the X chromosome reactivation (XCR) occurs during reprogramming is not yet fully understood. Here, we set out to elucidate the X chromosome reactivation during reprogramming of human female somatic cells. Interestingly, we found that there is a wave of transition in X chromosome status during and after reprogramming.

While cells actively undergoing reprogramming show the XCR, completion of reprogramming results in X chromosome inactivation, followed by XCR in select iPSC clones. Our findings show the dynamic X chromosome change occurs during human female somatic cell reprogramming.

W-2125

REPROGRAMMING TO PLURIPOTENCY BY SALL4, NANOG, ESRRB AND LIN28 PRODUCES HIGH QUALITY IPSCS WITH HIGH SUCCESS RATE AND DEFINES A MOLECULAR SIGNATURE OF IPSC DEVELOPMENTAL COMPETENCE

Yossi Buganim, Styliani Markoulaki, Batool Akhtar-Zaidi, Rudolf Jaenisch
WIBR, Whitehead Intitute, Cambridge, MA, United States

induced pluripotent stem cells (iPSCs) exhibit high variation in their developmental potential and a large proportion of them are of low developmental capacity as measured by stringent pluripotency assays such as chimera formation and tetraploid complementation assay (4n assay). As a result a large number of iPS colonies need to be screened in an attempt to find a high quality iPS line. This problem is even more amplified in human cells because they lack stringent pluripotency assays. Thus, finding a protocol that yields, with a high success rate, high quality iPSCs is an indispensable prerequisite for future iPSC-based therapy. Here we show that ectopic expression of Sall4, Nanog, Esrrb and Lin28 (SNEL) in mouse embryonic fibroblasts (MEFs), although produced low number of iPS colonies, generated with high efficiency high quality iPSC colonies as compared to Oct4, Sox2, Klf4 and c-Myc (OSKM). SNEL-iPSC colonies contributed to high-grade chimaeras and produced “all-iPS” mice by 4n assay. Whole genome transcriptional profile and bisulfite sequencing revealed distinct signatures of 1765 genes and 112 differentially methylated regions (4n-DMRs) that robustly distinguish lines that are 4n proficient from those that are not. Taken together, our results suggest that reprogramming factor combinations are critical determinants of iPSC quality and appropriate resetting to the pluripotent transcriptional and epigenetic states.

W-2126

PATIENT-DERIVED CONGENITAL ERYTHROPOIETIC (CEP) CELLS DISPLAY PHOTOSENSITIVITY DURING REPROGRAMMING

Suzanna Katz[1], Caroline Hendry[2], Dung-Fang Lee[2], Senkottuvelan Kadirvel[3], Sonia Clavero-Villarrub[3], David Bishop[3], Robert Desnick[3], Ihor Lemischka[2]
[A]Pharmacology and Systems Biology, [B]Developmental and Regenerative Biology, [C]Genetics and Genomic Sciences, [1]ICAHN School of Medicine at Mount Sinai, New York, NY, United States

Congenital Erythropoietic Porphyria (CEP) is a rare disorder of heme biosynthesis caused by an autosomal recessive mutation in the enzyme uroporphyrinogen III synthase (URO-synthase), which results in deficiency of heme production and the accumulation of porphyrins in the body. CEP is one of the most severe Porphyrias (a group of disorders affecting the heme biosynthetic pathway), with symptoms beginning soon after birth or in early childhood. Skin photosensitivity is one of the major clinical manifestation of porphyrin, resulting in severe blistering and scarring, often to the point of disfigurement. Patient samples of two unrelated patients with CEP were obtained in order to develop an in vitro disease model of CEP using stem cell technologies. Patients B1199 and B1340 have identical homozygous mutations that result in the most severe manifestation of CEP (resulting from <1% UROS activity). Thus, reprogramming fibroblasts from CEP patients into induced Pluripotent Stem Cells (iPSCs) would provide opportunities not only for greater understanding of disease pathobiology, but also for pharmacological testing and gene therapy clinical applications. However, since iPSCs are thought to be in an ‘open’ chromatin state, it was reasoned that promiscuous heme pathway activation would impede iPSC formation in CEP cells due to porphyrin induced photosensitivity. In order to determine if iPSC formation is light sensitive, CEP (B1199) and WT fibroblasts were infected with lentivirus and observed in light, dark, and UV conditions (daily exposure to 405nm light) during the reprogramming process. After several weeks, ~5-fold less Nanog+ colonies were observed in the light conditions, whereas the number of colonies from the WT cells remained the same. No colonies formed under the UV conditions, however

these conditions also drastically reduced the number of WT colonies too. Since photosensitivity was observed even during the reprogramming of CEP fibroblasts into the pluripotent state, iPSCs have been made via Sendai virus for the CEP Patients B1199 and B1340 in 100% dark conditions under far red light. This attempt yielded many colonies per line, several of which have been picked and expanded to passage 14. Established patient-derived iPSCs will allow us to elucidate the mechanism of light sensitivity in CEP and provide the ability to test clinical interventions in a safe and scalable way.

W-2127

USING HUMAN PATIENT SPECIFIC IPSC DERIVED EYE CUPS TO INTERROGATE AND TREAT INHERITED RETINAL DEGENERATION

Budd A. Tucker[1], Robert F. Mullins[1], Arlene Drack[1], Kristin Anfinson[1], Emily Kaalberg[1], Edwin M. Stone[2]
[1]Ophthalmology, University of Iowa, Iowa City, IA, United States, [2]Ophthalmology, University of Iowa, HHMI Investigator, Iowa City, IA, United States

Purpose: Retinitis pigmentosa (RP) is a genetically heterogeneous heritable disease characterized by apoptotic death of light sensing photoreceptor cells. Mutations in as many as 100 different genes are predicted to cause this disease. Many genes such as USH2A, are large and highly polymorphic and thus it is useful to be able to functionally confirm potential new disease-causing mutations in retinal cells prior to development of gene and/or cell based therapies. This is especially true for non-exomic mutations whose pathogenicity is difficult or even impossible to confirm at the DNA level. The purpose of this study was to develop patient specific retinal tissue for the interrogation of potential disease causing mutations and for development of new gene- and cell-based therapies.
Methods: iPSCs were generated via transduction of human keratinocytes, obtained from patients with USH2A-associated retinitis pigmentosa, using the transcription factors Oct4, Sox2, C-Myc and KLF4. iPSC potency was analyzed via ICC, WB, and teratoma formation. Capacity for retinal differentiation was determined via ICC, rt-PCR, and WB analysis of recoverin, rhodopsin, ROM-1, R/G opsin, B-opsin, and tubulin. To determine the capacity for cellular integration and photoreceptor maturation, subretinal transplantation into CRB1 null mice was performed. Pathogenicity of USH2A mutations was determined via rt-PCR targeted against USH2A.
Results: iPSCs generated from a patient with suspected USH2A associated RP were generated. Following differentiation, eyecups containing both RPE and neural retina were generated. Isolation, expansion and focused analysis of the pigmented and non-pigmented layers of patient specific eye cups allowed us to confirm RPE and photoreceptor cell lineage. Likewise transplantation of cells obtained from the neural retina into CRB1-null mice gave rise to newly generated photoreceptor cells. Analysis of the USH2A transcript within the neural retina revealed that a suspected splice site mutation within IVS40, induced exonification of the intron and insertion of a premature stop codon. In addition, a novel mutation identified via next generation whole exome sequencing was also confirmed within the iPSC derived neural retina of the patient.
Conclusions: By combining exome sequencing and induced pluripotent stem cell (iPSC) technologies we have been able to definitively demonstrate the pathogenicity of two disease-causing mutations in a patient with late onset non-syndromic USH2A associated RP. These findings have enabled us to proceed with patient specific studies focused on USH2A gene correction and photoreceptor cell replacement.

W-2128

STUDY OF MECP2 FUNCTION IN RETT SYNDROME-DERIVED INDUCED PLURIPOTENT STEM CELLS USING TALEN TECHNOLOGY

Ileana Slavin[1], Pablo Perez-Pinera[2], Charles A. Gersbach[2], Jeanne Loring[1]
[1]The Scripps Research Institute, La Jolla, CA, United States, [2]Duke University, Durham, NC, United States

Rett syndrome is a neurodevelopmental disorder caused by mutations in methyl CpG binding protein 2 (MECP2), a gene located on the X chromosome. Affected females carry one mutant copy and one normal copy in each of their

cells; however, due to X-chromosome inactivation (XCi), in any given cell, either the mutant copy or the normal copy is active, leading to mosaicism. The stochastic nature of X-inactivation results in a range of clinical severity, depending on the fraction of cells in the brain that have inactivated the mutant versus the wild-type copy of MECP2. This mosaicism, and the resulting heterogeneity in cellular phenotype, makes studies of MECP2 dysfunction in Rett Syndrome patients challenging.
In order to develop an in vitro model of Rett syndrome to study the involvement of MECP2 mutations in neural differentiation, function, and survival, we have generated iPSCs from dermal fibroblasts from 3 Rett syndrome patients. Several iPSC clones for each mutation were fully characterized for pluripotency and we determined the allelic expression of the MECP2 gene. These iPSC lines were also differentiated along a neuronal lineage and shown that all of them can become functional neurons.
X-chromosome inactivation often degrades over time during culture of iPSCs, resulting in cells that express both copies of X-linked genes, which complicates their use as models for X-linked diseases. To overcome this problem, we are using TALEN technology to target MECP2 in heterozygous female Rett iPSC lines to make paired isogenic iPSC lines that are either homozygous wild-type or mutated cell lines, in which MECP2 expression will not depend on XCi. These lines will be valuable tools to study the effects of the MECP2 mutations by comparing cells that are genetically identical except for the mutation. The ability to correct the mutation may also allow us to investigate the feasibility of gene therapy for treatment of Rett syndrome.

W-2131

GLOBAL GENE REGULATION BY METHYL CPG BINDING PROTEIN 2 (MECP2) IN PLURIPOTENT STEM CELLS

Yoshiaki Tanaka, Kun-Yong Kim, Mei Zhong, Xinghua Pan, Sherman M. Weissman, In-Hyun Park
Genetics, Yale School of Medicine, New Haven, CT, United States

Introduction
Rett syndrome (RTT) is one of the most prevalent female mental disorders. De novo mutations in methyl CpG binding protein 2 (MeCP2) are a major cause of RTT. MeCP2 regulates gene expression as a transcription regulator as well as through long-range chromatin interactions. Because MeCP2 is present on the X chromosome, RTT is manifested in a X-linked dominant manner. Murine MeCP2 null models and post-mortem human brain tissues have contributed to understanding the molecular and physiological function of MeCP2. In addition, RTT models using human induced pluripotent stem cells derived from RTT patients (RTT-iPSCs) provide novel resources to elucidate the regulatory mechanism of MeCP2. Previously, we obtained clones of female RTT-iPSCs that express either wild type or mutant MeCP2 due to the inactivation of one X chromosome. Reactivation of the X chromosome also allowed us to have RTT-iPSCs that express both wild type and mutant MeCP2. Recent studies showed that MeCP2 plays a critical role in astrocytes, microglia and mesenchymal stem cell, suggesting the critical role of MeCP2 in non-neuronal cells is important. Using our unique pluripotent stem cells, we investigated the regulation of gene expression by MeCP2 in pluripotent stem cells.
Results
We performed massively-parallel RNA sequencing (RNA-seq) in RTT-iPSCs from five different patients as well as normal ESCs/iPSCs. Although the expression of MeCP2 is relatively lower in pluripotent stem cell compared with neuron, our transcriptome analysis shows dysregulation of developmental genes in RTT-iPSCs. First, RTT-iPSCs expressing mutant MeCP2 lack several iPSC-specific genes, such as TMEM132D and FAM19A5. We also found that MeCP2 mutation induces overexpression of mitochondrial respiratory chain-related genes, resulting in reduction of apoptosis. In addition, even in pluripotent stem cell, MeCP2 mutation is involved in the regulation of genes related with neuronal development, but each mutation affects a partly different set of genes. Furthermore, loss of function in MeCP2 results in de-repression of genes on the inactive X chromosome.
Conclusion
These studies suggest that fundamental cellular physiology is affected by mutations in MeCP2 from very early fetal development and that a therapeutic approach targeting to unique forms of mutant MeCP2 is needed.

W-2132

PERSONALIZING THE STUDY OF INFECTIOUS DISEASE: MODELING HEPATITIS C VIRUS USING INDUCED PLURIPOTENT STEM CELLS

Robert E. Schwartz[1], Kartik Trehan[1], Linda Andrus[2], Timothy Sheahan[2], Alexander Ploss[2], Stephen Duncan[3], Charles Rice[2], Sangeeta N. Bhatia[1]

[1]Harvard–MIT Division of HST, Massachusetts Institute of Technology, Cambridge, MA, United States, [2]The Center for the Study of Hepatitis C, The Rockefeller University, New York, NY, United States, [3]Medical College of Wisconsin, Department of Cell Biology, Milwaukee, WI, United States

Human pathogens are responsible for 90% of human disease and 32% of deaths worldwide. Improved understanding of host-pathogen interactions will accelerate progress towards clinical therapy. The role that host genetics play in the natural history of infection and response to clinical therapy is poorly understood. Person-to-person variations in infection outcomes have long been appreciated, and genome-wide association studies are identifying predictive genetic signatures for these outcomes. Despite this progress, it is not generally possible to elucidate the interplay between genetics and infection due to the lack of model systems that capture host genetics. Achieving "personalized medicine" for infectious disease, whereby it would be possible to stratify patients genetically to make tailored clinical predictions and therapeutic recommendations, necessitates in vitro models that can systematically be sourced from genetic backgrounds of interest. We leverage induced pluripotent stem cells (iPSCs), which open the door to producing person-specific adult cell-types and tissues. We tested the feasibility of this experimental paradigm for a clinically relevant pathogen; hepatitis C virus (HCV) in stem cell derived hepatocytes. iPSC were differentiated towards hepatocyte-like cells (iHLCs) in a step-wise manner as exemplified by co-expression of multiple markers including albumin and alpha-1-antitrypsin, and secretion of liver-specific proteins. iHLCs were shown to express host factors important for HCV infection including CD81, SRB1, claudin1, and occludin. iHLCs infected with HCV demonstrate drug-sensitive viral replication. Transfer of supernatants from infected iHLCs to uninfected cultures showed the transmission of infection, verifying that infected iHLCs produce infectious virions and thus recapitulate the entire viral life cycle. Quantitative real-time PCR revealed that expression of inflammatory markers was up-regulated by HCV infection, demonstrating that HCV elicits a robust antiviral inflammatory response in iHLCs, a critical aspect of HCV pathogenesis in vivo. Finally, iHLCs derived from LDLR knockout patients had diminished infection compared to iHLCs derived from normal patients. This demonstrates for the first time that iPS and iPS derived hepatocyte-like cells can be used to explore the role that person-to-person variations play in HCV infection and more broadly viral pathogenesis.

TCL1 OVEREXPRESSION HIGHLIGHT THE RELATIONSHIP BETWEEN PLURIPOTENCY AND TUMORIGENICITY

Tathiane M. Malta[1], Virginia Picanço-Castro[2], Daniel G. Pinheiro[1], Elisa M. Russo[1], Evandra S. Rodrigues[1], Rodrigo A. Panepucci[1], Dimas T. Covas[1], Simone Kashima[1]

[1]Univ of Sao Paulo, Ribeirao Preto, Brazil, [B]Regional Blood Center of Ribeirao Preto, [1]Univ of Sao Paulo, Ribeirao Preto, Brazil

Induced pluripotent stem cells (iPS) provide an unprecedented platform to model human disease, to screen for pharmacological molecules, and offer novel therapeutic strategy to generate patient-specific stem cell lines. However, iPS cells, and ESCs as well, have a tumorigenic potential that represents an obstacle to the safe use of pluripotent stem cell-based regenerative medicine therapies. Indeed, the relationship between tumorigenicity and pluripotency is largely unknown, but it seems that they are very related process.
With this in mind, the aim of this study was to analyze the contribution of TCL1A for reprogramming and if it plays a role in tumorigenicity. For this, we forced expression of TCL1A in fibroblasts and analyze their global expression profile.
We cultured the TCL1 transduced cells in embryonic stem cell condition. Interestingly, we observed a change in their morphology. The cells acquired a colony-like morphology with no defined edges. These cells were positive for

Nanog expression and negative for Oct4 and SSEA-4, by flow cytometry. The cells did not show alkaline phosphatase activity. Then, we used a microarray platform and found 3,491 genes (fold change greater than 2) that had been activated and repressed in the transduced cells compared to the donor fibroblasts. When we looked for the most represented molecular and cellular functions among the upregulated genes in TCL1-transduced cells, we found the following functions: cell cycle; cellular assembly and organization; and DNA replication, recombination, and repair. The upregulated genes included E2F1, E2F2, and CDK1. These finding suggest that TCL1 overexpression contributed for cell proliferation, which is important for pluripotency induction and for tumorigenicity as well. Although we observed SOX2 and SALL4 upregulation in TCL1-transduced cells, TCL1 alone was not able to activate pluripotency pathway.

When we take into account the downregulated genes in TCL1-transduced cells we found cellular movement; cellular development; and cell-to-cell signaling and interaction as the most represented functions. Cellular development encompassed genes related to epithelial-mesenchymal transition (EMT), including TWIST1, TWIST2, ZEB1, ZEB2, and SNAI2. We also observed downregulation of COL1A1, COL1A2, ACTA2, and MMP9. Together with CDH1 upregulation, these findings indicate that TCL1 overexpression contribute to EMT/MET process, which is related both to cancer and to pluripotency induction.

TCL1 was one of the 24 molecules tested by the first authors who derived iPS cells. It had been chosen because it is overexpressed during embryonic development. TCL1 is also overexpressed in human malignancies, which highlight the relationship of pluripotency and tumorigenicity. In fact, to induce pluripotency we need to induce self-renewal, which is also a property of tumors. The safety of stem cell regenerative therapies depends on how we will be able to control self-renewal and pluripotency and at the same time avoid tumorigenicity.

Although TCL1 seems not to contribute for pluripotency induction, it was able to induce molecular and cellular functions that are important for the reprogramming process, reinforcing the relationship between tumor and pluripotency.

W-2134

INCOMPLETE TELOMERE REPROGRAMMING UNDERLIES DEFECTIVE SILENCING OF EXOGENES IN PORCINE IPS CELLS

Guangzhen Ji[1], Kai Liu[1], Fang Wang[1], Sarantis Gagos[2], Lai Liangxue[3], Lei Xiao[4], Hongkui Deng[5], Ning Li[6], Lin Liu[1]

[1]Department of Cell Biology and Genetics, Nankai University, Tianjin, China, [2]Biomedical Research Foundation of the Academy of Athens Greece (BRFAA), Athens, Greece, [3]Guangzhou Institutes of Biomedicine and Health, Guangzhou, China, [4]Stem Cell and Developmental Biology Research Center, Zhejiang University, Hangzhou, China, [5]College of Life Sciences, Peking University, Beijing, China, [6]State Key Laboratory for Agrobiotechnology, China Agricultural University, Beijing, China

Sufficient telomere reprogramming and telomerase activation are critical for induction and self-renewal of pluripotent stem cells. Telomeres can be effectively reprogrammed and exogenous genes are fully silenced in mouse and human induced pluripotent stem (iPS) cells. However, exogenous genes remained active in most of porcine iPS cells generated in many laboratories thus far. We performed a systematic analysis of telomere length and maintenance of various porcine iPS cells generated from different cell types using various methods. We show that insufficient telomerase activation and incomplete telomere reprogramming were associated with many porcine iPS cell lines.

Porcine iPS cells at early passages (p5-10) with continuously activated exogenous genes exhibited telomere elongation and activation of telomerase to various degrees, compared to their progenitor cells, and their telomeres elongated or maintained during passages. Thus, sustained activation of exogenes appeared to improve telomerase activity and facilitate telomere elongation. In contrast, porcine iPS cells with silenced exogenous genes exhibited telomere shortening with increasing passages. Silencing or partial silencing of the exogenes was found in rare porcine iPS cells at early passages, yet the exogenes became reactivated during passages and this often was associated with insufficient activation of endogenous pluripotent genes and telomerase genes, leading to increased telomere damages and chromosomal instability. Moreover, porcine iPS cells had higher frequency

of telomere sister chromatid exchanges and t-circles that are involved in telomere lengthening by recombination. Nonetheless, they also showed increased frequency of telomere doublets, coincided with elevated telomere dysfunction induced foci, indicative of telomere damages. Notably, porcine iPS cells with reduced expression of pluripotent genes and telomerase genes exhibited increased frequency of DNA and telomere damages, which also increased with the passage numbers. Severe damages to DNA and telomeres led to elevated genomic instability as shown by abnormal karyotypes. The unique characteristics of porcine telomeres may partially explain failed telomere maintenance and reactivation of exogenes in porcine iPS cells during prolonged culture. Since authentic porcine ES cells still are not readily available as standard references for comparing the expression levels of pluripotent genes in porcine iPS cells, we speculated that exogenous genes remained to be activated to compensate for insufficiently activated endogenous pluripotent genes and to maintain telomeres in porcine iPS cells. Regardless of exogene inactivation, both telomerase-dependent and telomerase-independent mechanisms are involved in telomere reprogramming during induction and passages of porcine iPS cells. Further dissection of these pathways may help deeper understanding of telomere reprogramming and maintenance in porcine iPS cells. Also, the improvement in the induction method and culture conditions is required to fully activate endogenous genes and maintenance of telomeres, and thus will likely generate authentic pluripotent porcine iPS cells.

W-2135

REGULATION OF WNT SIGNALING DURING ANDROGEN RECEPTOR-MEDIATED APOPTOSIS IN BOVINE TESTICULAR INDUCED PLURIPOTENT STEM CELLS IN RESPONSE TO PHTHALATE ESTERS

Chia-Chen Ku[1], Ying-Chu Lin[1], Yukio Nakamura[2], Shigeo Saito[1], Kazushige K. Yokoyama[1]
[1]Koahsiung Medical University, Kaohsiung, Taiwan, [2]RIKEN BRC, Tsukuba, Japan

The induced pluripotent stem cells (iPSCs) were generated from bovine testicular cells by electroporation of Pou-domain transcription factor Oct4. Supplementation with leukemia inhibitory factor and bone morphogenetic protein 4 maintained and stabilized the expression of stemness genes and pluripotency. Bovine iPSCs displayed the normal karyotype and expressed alkaline phosphatase, SSEA-1, and SSEA-4. It expressed the stemness genes including OCT4, NANOG, MYC, KLF4, SOX2, STAT3, DNMT1, SUZ12, and MEF2A, and differentiated into cell types of all three germ layers in teratomas. We have also examined the effects of phthalate derivatives such as di-n-butyl phthalate (DBP), butylbenzyl phthalate (BBP), and di (2-ethylhexyl) phthalate (DEHP). The addition of DEHP repressed the expression of androgen receptor (*AR*) gene and the ability of iPSCs to commit to apoptosis. This was mediated by increased expression of $p21^{Cip1}$. DBP and BBP had no such effect. Loss of Wnt/β-catenin signaling, especially activities of the Frizzed receptor and Disheveled, was responsible for the effect of DEHP on AR-mediated apoptosis. Thus, the iPSCs from testicular cells are useful for screening the toxicity of environmental disruptors in terms of maintenance of stemness and pluripotency.

W-2136

ESSENTIAL ROLES OF TET1 IN MOUSE AND HUMAN PLURIPOTENCIES

Hidemasa Kato, Keiko Hiraki
Saitama Medical Univ, Hidaka, Japan

Mouse ESCs (mESCs) are largely accepted to have genuine self-renewing capacity and pluripotency. In contrast, human ESCs (hESCs) which are derived from the blastocyst but are more akin to the later epiblast-stage embryos show some resistance and biases toward differentiation. Moreover, human iPS cells (hiPSCs) tend to have lower self-renewal capacity when compared to mESCs and even to hESCs. Why all these cell populations differ this much? We here postulated that this could be because hiPSCs have not passed through a blastocyst-stage like other pluripotent stem cells (PSCs). We focused on proteins which expressions are present in blastocysts but not in the ensuing epiblasts. Tet1 was found to be such a protein. Our investigation indicated that Tet1 is involved in harnessing the full differentiation potential of mESCs. Without Tet1, the differentiation of mESCs decelerates which leads to a dif-

ferentiation resistance. Also in the mouse, Tet1 is only expressed up to the blastocyst stage. As the current method for deriving hiPSCs stands, we believe that hiPSCs would have little chance to ever express TET1, which may explain the differentiation defects of these cells. Therefore, we over-expressed TET1 in hiPSCs and its effects were studied. By comparing wild-type hiPSCs and TET1-overexpressing hiPSCs (TET1-hiPSCs), we found that the self-renewal ability has been improved upon TET1 expression. Next, we tested the pluripotency of the TET1-hiPSCs. When assigned to neuronal differentiation, these cells exhibited markedly higher efficiencies. Judging from the levels of SOX1, we found a 60-times increase in its efficiency when compared to wild-type hiPSC differentiation. We therefore concluded that the presence of TET1 reduces an inherent differentiation resistance of hiPSC, at least for the neural lineage, educing the bona fide pluripotency of these cells. An important implication is whereas “full” pluripotency may not strictly be necessary for life as judged by viable Tet1-KO mice, it is definitely needed for practical usages of PS cells. Our results are suggestive that Tet1 seems to be in charge of this “full” pluripotencies in both mouse and human PS cells and its absence in human pluripotency strongly damages its practical usages.

IMAGE-BASED IRREGULAR IPS COLONY DETECTION FOR INTELLIGENT AUTOMATED CELL CULTURE

Megumi Matsumoto[1], Hiroto Sasaki[1], Risako Joto[2], Mika Suga[3], Masaki Kinehara[3], Kana Yanagihara[3], Yasujiro Kiyota[4], Kei Kanie[2], Hiroyuki Honda[1], Miho K. Furue[3], **Ryuji Kato**[2]
[A]Graduate School of Engineering, [B]Graduate School of Pharmaceutical Sciences, [1]Nagoya University, Nagoya, Japan, [2]Laboratory of Stem Cell Cultures, Department of Disease Bioresources, Research, National Institute of Biomedical Innovation, Ibaraki, Japan, [3]Nikon corporation, Tokyo, Japan

Pluripotent stem (PS) cell technology is the promising approach that widely expands the new approaches of pharmaceutical discoveries and regenerative medicine. However, including the recent progress of iPS cell researches, it still requires experienced technique to properly culture and maintains PS cells in stable undifferentiated status to provide reliable outputs in further usages. In spite of the accumulating knowledge of stem cell markers for evaluating the cellular status, it is widely known that the “colony morphology” is one of the most reliable markers to monitor or select the desirable PS cells. Commonly, PS cell colonies which clear and smooth edges with tight density is an aspect of desirable PS cell status, and colonies with “irregular morphology”, which consist of various types of irregular morphology, is known as the indication of undesirable PS cells. However, such morphological “definition by words” could not always fully reflect the information that used in experts’ recognition. Together with the biases of microscopic images, such as focus, brightness, view fields, timings, and etc., such image-based recognition was left in the black box of cell culture experts.
Here we propose a new methodology that combines automated cell culture observation system together with the colony morphology typing algorithm, which calculates the morphological feature data quantitatively, to automatically recognize the “irregular colony morphology” only from the images. Our data indicates that the morphological type that we recognize by our algorithm is detecting the irregular genetic profiles that arise in populations of iPS colonies.

ENHANCED MAINTENANCE OF GENETIC INTEGRITY IN INDUCED PLURIPOTENT STEM CELLS

I-Chung Chen, John R. McCarrey
Biology, The University of Texas at San Antonio, San Antonio, TX, United States

During the past seven years, induced pluripotent stem cells (iPSCs) have revolutionized the stem cell field because these cells can be directly generated from various types of differentiated somatic cells using viral transduction or non-viral induction with pluripotency factor genes, RNAs or proteins, without the involvement of embryos. Thus, iPSCs are viewed as a preferable source of patient-specific pluripotent stem cells for uses in future clinical applications. However, the fact that iPSCs are derived from differentiated somatic cells raises certain concerns about the

safety of their use for therapeutic applications. One concern is that differentiated somatic cells typically bear a significantly greater mutational load than germ cells or early embryonic cells. Indeed, in our published and unpublished studies we have used the Big Blue Transgenic Mouse (BBM) system carrying the lacI mutation-reporter transgene to demonstrate that frequencies of spontaneous point mutations in differentiated somatic cells are significantly higher than those in germ cells, early embryonic cells, and embryonic stem cells (ESCs). This raises a question about the frequencies of spontaneous mutations in iPSCs and whether these will be more similar to the higher frequencies found in the somatic cells from which the iPSCs are derived or the lower frequencies found in other types of pluripotent cells which these cells resemble.
To test this question, we have generated iPSCs from mouse embryonic fibroblasts (MEFs) and adult tail-tip fibroblasts (TTFs) heterozygous for two different transgenes - 1) a drug-inducible cassette encoding four reprogramming factors, and 2) the BBM lacI mutation-reporter transgene. We obtained twelve MEF-derived, twenty TTF-derived, and six subcloned TTF-derived iPSC lines. All lines showed standard mouse ESC/iPSC colony morphology. Four MEF-derived, four TTF-derived and one TTF-derived subcloned iPSC lines were characterized for expression of mouse pluripotency markers, alkaline phosphatase, OCT4, SOX2, NANOG and SSEA-1, and found to be positive. Preliminary measurements of the frequency of spontaneous mutations in a population of MEFs and in an iPSC line derived from these MEFs indicate the mutation frequency in the iPSCs is significantly lower than that in the MEFs. Analyses of additional iPSC lines are underway. If we observe consistently lower frequencies of mutations in iPSCs than in the somatic cells from which they are derived, it will suggest that enhanced maintenance of genetic integrity occurs as a consequence of epigenetic reprogramming associated with converting differentiated somatic cells into iPSCs, consistent with our primary hypothesis that pluripotency and enhanced maintenance of genetic integrity are mechanistically linked at the genomic level.

TAQMAN TRANSCRIPTOME ASSAYS FOR RAPID ASSESSMENT OF GENOME, EPIGENOME AND QUALITY OF INTEGRATION-FREE INDUCED PLURIPOTENT STEM CELLS

Uma Lakshmipathy[1], Rene Quintanilla[1], Andrew Fontes[1], Jeffrey Fergus[1], Candida Vaz[2], Vivek Tanavde[2]
*[1]Primary and Stem Cell Systems, Life Technologies, Carlsbad, CA, United States, [2]Bioinformatics Institute, A*STAR, Singapore, Singapore*

Pluripotent stem cells such as embryonic stem cells (ESC) and induced pluripotent stem cells (iPSC) are commonly identified and characterized based on biomarker expression. Current methods rely on a combination of in vitro and in vivo cellular methods to confirm pluripotency and tri-lineage differentiation potential. As the bottleneck in efficiency of reprogramming is alleviated with faster and better reprogramming systems, there is a need for high throughput characterization methods that allow for rapid confirmation of the quality of the resulting iPSC.
Molecular analysis platforms offer a quantitative, accurate and fast alternative to current methods and have recently been utilized to qualify pluripotent stem cells. Several platforms are available for gene expression analysis varying in content and complexity. To determine the optimal method and minimal set of genes required for definitive characterization of pluripotency, we have utilized high density array, medium and low density TaqMan® qPCR arrays to compare expression pattern of partially reprogrammed clones and fully reprogrammed iPSC in comparison to parental fibroblast and control embryonic stem cells. Results indicate that a focused set of genes in low and medium density arrays can recapitulate the information obtained with large scale arrays with distinct clustering of samples based on their pluripotency that correlated with cellular data. Further, this method was used to identify unique genes that were expressed differentially between partially reprogrammed cells and true iPSC clones as well as pluripotent cells and cells randomly differentiated via embryoid body formation.
Additional assays were carried in parallel to assess epigenome signature using TaqMan® Array Human MicroRNA Card and TaqMan® assays for copy number variation. Comprehensive analysis of the resulting data indicates similarities between the pluripotent clones but also detects subtle differences that can be further evaluated for their impact on functionality and long-term stability.

GENERATION OF DISEASE-SPECIFIC INDUCED PLURIPOTENT STEM CELLS FROM POLYCYSTIC KIDNEY DISEASE PATIENTS

Wang Yang[1], Huang Jiahui[1], Tian Shoufu[1], Niu Xin[1], Hu Bin[1], Guo Shangchun[1], Chen Qinkai[2]

[1]Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China, [2]Department of Nephrology, The First Affiliated Hospital of Nangchang University, nanchang, China

Abstract

Introduction: Autosomal dominant polycystic kidney disease (ADPKD) is a common, monogenic multi-systemic disorder characterized by the development of renal cysts and various extrarenal manifestation, affecting approximately 7 million people worldwide. Mutations in the PKD2 gene is responsible for ADPKD in 15% patients. Recent studies have reported that induced pluripotent stem (iPS) cells hold promise to develop cell therapies and study disease mechanisms by genetic modification in vitro. So we selected the patients' differentiated fibroblasts with ADPKD for reprogramming of iPS cells line.

Methods: We screened a family with ADPKD, then obtained fibroblasts from the family members and a healty donor. These fibroblasts were infected by retrovious vectors encoding the human transcription factors (oct4, sox2, klf4 and c-myc) to generate iPS. Alkaline phosphatase staining was used to analyses the undifferentition phase of the ADPKD-iPS. Immunocytochemistry and Flow cytometry analyses were performed to test cell surface markers and pluripotency genes. Chromosomal G-band were used to analyses karyotype. Embryoid Body-mediatedand differentiation and teratoma formation demonstrated that iPS cells could differentiate into three germ layers in vitro/vivo. Sequence analysis of the whole PKD gene in the iPS line revealed a heterozygosity missense mutation.

Results: The ADPKD-ips cells exhibited morphology similar to human ES cells, characterized by large nuclei and scant cytoplasm with distinct borders . All of the ADPKD-iPS cells were positive for alkaline phosphatase . ADPKD-iPS cells were verified for the presence of cell surface markers (SSEA-4, TRA-1-60, TRA-1-81, Sox2, Oct4) and expressed pluripotency genes OCT4 by Flow cytometry analyses. Chromosomal G-band analyses demonstrated that iPS cells line had the same karyotype (46, XY) as the parent fibroblasts cells. Sequence analysis of the PKD2 gene confirmed a heterozygosity missense mutation: a GGG to GAA mutation at exon 1,which has not been reported before.

Conclusions: Our results demonstrate successful iPS cells generation from patients with a history of PKD gene mutation. iPS cells derived from ADPKD patients would provid a promising resource to study disease mechanisms, screen novel drug compounds, and develop new therapies.

GENERATION OF PORCINE IPS CELLS FROM ADIPOSE-TISSUE MESENCHYMAL STEM CELLS (PASCS) AND IMPROVED MAINTENANCE AND PASSAGING BY THE USE OF INACTIVATED PASC AS FEEDER

Diogo G. Biagi[1], Rafael Dariolli[1], Gustavo Mostoslavsky[2], Alexandre C. Pereira[1], Jose E. Krieger[1]

[1]Laboratory of Genetics and Molecular Cardiology, Heart Institute - InCor - University of Sao Paulo Medical School, Sao Paulo, Brazil, [2]Department of Medicine, Boston University School of Medicine, Boston, MA, United States

Adipose derived stem cells have been broadly used in cell therapy; however, they exhibit great limitations in their potential of differentiation to specific cell types. In contrast, a more robust differentiation potential may be achieved by reprogramming of somatic cells to a pluripotent state, such as induced Pluripotent Stem-Cells (iPSCs) capable of differentiating a variety of cell types. AIM: The aim of the present work was to generate porcine iPSCs (piPSCs) from Adipose-tissue mesenchymal Stem Cells (pASCs) and the evaluation of pASCs viability as feeder for the generated iPSCs. METHODS: pASCs extracted from an adult pig were grown until passage 5 and then transduced with a polysistronic lentiviral vector (STEMCCA). Two days after transduction, 2x104 cells were transferred to a 35 mm dish coated with Matrigel (BD Biosciences, NJ, USA) and cultured with E8 (Invitrogen, CA, USA) com-

plemented with 0.5 uM sodium butirate (Sigma, MO, USA). Medium was changed every other day until day 10 and every day until day 15-17. After picking, cells were cultured on matrigel coated dishes and medium was changed daily. RESULTS: On day 17, after viral transduction, colonies with morphology resembling human embryonic stem cells (hESCs) were manually picked. Nine of the 12 colonies selected grew until passage 4 and exhibited Alkaline Phosphatase (PA) activity. These colonies exhibited growth characteristics similar to hESCs, except for a higher rate of spontaneous differentiation (30%). After passage 4, two clones (piPSC-610 and piPSC-617) were selected to further expansion. We tested the expansion with two types of feeder: inactivated mouse Embryonic Fibroblast (mEF) at passage 5 and inactivated pASCs at passage 6. Feeders were plated at 0.4x103/mm2. Both clones decreased the spontaneous differentiation rate to 1-3%; however, pASC colonies took two passages to reach this value while mEF colonies took 4 passages. Moreover, colonies in pASC grew quicker and displayed lower rates of cell death and differentiation in the center of the colony compared to colonies grown in mEF. Finally, all colonies expressed molecular markers (RT-PCR for endogenous OCT4 and SOX2; NANOG, DNMT3b, and DPPA5) for the pluripotent state. Immunofluorescence results demonstrated that piPSCs expressed stem cell markers OCT-4, NANOG, SSEA-4 and TRA-1-60. Both clones formed embryoid bodies showing the markers of the three germ layers (NESTIN for ectoderm, DES for mesoderm and NCSTN for endoderm). CONCLUSION: We believe we provided the first evidence for porcine iPSCs generation from pASC and that pASC can be successfully used as feeder for piPSCs.

MOUSE INDUCED PLURIPOTENT STEM CELLS TRANSPLANTATION RESCUE INJURED MOTONEURONS

Krisztian Pajer[1], Csilla Nemes[2], Sara Berzsenyi[2], Antal Nógrádi[1], **Andras Dinnyes**[2]
[1]Department of Ophthalmology, University of Szeged, Szeged, Hungary, [2]BioTalentum Ltd, Godollo, Hungary

Plexus injuries often result in the avulsion of one or more ventral roots, leading severe loss of motoneurons. Novel therapeutic approaches aiming to treat and alleviate the consequences of motoneuron death involve transplantation of stem cells, including induced pluripotent stem cells (iPSCs).
Here we report that mouse induced pluripotent stem cells are able to integrate in the host cord, rescue injured rat host motoneurons and promote their regeneration following transplantation into the spinal cord.
Mouse iPSCs generated by purified reprogramming protein (Klf4, Oct4, Sox2 and c-Myc) transduction were transplanted into the caudal part of the lumbar 4 (L4) segment of Sprague Dawley adult rats following the avulsion of the left L4 ventral root. The transplanted cells were mapped 5, 10 and 90 days after surgery using mouse specific antibodies to detect neuronal marker M6, astroglia marker M2 and stage specific embryonic antigen-1 (SSEA1).
In the transplanted animals significantly more motoneurons survived and innervated the denervated hind limb muscles compared with control animals. In the first 7 days after transplantation, the iPSCs expressed the neutrophic factors (GDNF and NT-4) and pro- and anti-inflammatory cytokines (MIP-1 alpha and IL-10). From this time onwards, iPSCs-derived neurons and astrocytes migrated throughout the L4 spinal segment. From day 10 after transplantation, the microglial activity in the graft increased and after day 16, the iPSCs and they derivatives disappeared completely from the spinal cord.
These data show that the mouse iPSCs differentiate into neurons and astrocytes in the injured spinal cord; express a set of molecules that promote the survival and regeneration of adult motoneurons after avulsion.

C-FLIP PROTECTS HUMAN PLURIPOTENT STEM CELLS FROM TRAIL INDUCED APOPTOSIS

Vladimir Vinarsky[1], Jan Krivanek[1], Ladislav Andera[2], Ales Hampl[1]
[1]Masaryk University, Brno, Czech Republic, [2]Institute of Molecular Genetics, Czech Academy of Sciences, Prague, Czech Republic

Human pluripotent cells are extremely sensitive to DNA damage and undergo swift apoptosis upon DNA damage. Whereas expression of intrinsic apoptotic pathway was investigated, virtually nothing is known about expression and functionality of extrinsic apoptotic pathway in human pluripotent stem cells. We for the first time aimed to characterize expression and functionality of extrinsic apoptotic pathway. We focused on TNF Related Apoptosis Inducing Ligand (TRAIL) binding receptors in human embryonic stem cells (hESC) and human induced pluripotent stem cells (hiPSC).
Two hESC lines and one line of hiPSC were assayed for presence of membrane bound TRAIL receptors (DR4, DR5, DcR1, DcR2). Common pattern of expression of TRAIL receptors was observed among all investigated cell lines. Apoptosis inducing receptors DR4 and DR5 were found to be significantly expressed. We also found that intracellular components of extrinsic apoptotic pathway components namely caspases 3, 8 and 10, Bcl2 family BH3-only proteins (Bax, Bid) were found to be expressed in both hESC and hiPSC in comparable amounts. However when we tested ability of TRAIL to induce apoptosis we observed little activation of caspases and negligible increase in programmed cell death in both hESC and hiPSC alike. In order to dissect molecular mechanisms underlying observed TRAIL resistance cells were sensitized to TRAIL using proteo-synthesis inhibition. We found that increased sensitivity to TRAIL was accompanied by decrease of c-FLIP, inhibitor of caspase 8 activation, hinting at possible mechanism. We functionally tested role of c-FLIP by construction of cell lines with c-FLIP knockdown and found pronounced increase of apoptosis susceptibility upon TRAIL treatment in cells with decreased levels of cFLIP.
In this work we have for the first time mapped expression and functionality of TRAIL receptors and extrinsic apoptotic pathway in two types of human pluripotent stem cells- human embryonic stem cells and induced pluripotent stem cells. We found that irrespective of their origin human pluripotent stem cells are TRAIL resistant. Moreover we show that reduction of c-FLIP removes this resistance to TRAIL what indicates important role of c-FLIP in regulation of apoptotic signaling in human pluripotent stem cells.

DEVELOPING A HUMAN INDUCED PLURIPOTENT STEM CELL DERIVED NEURAL STEM CELL MODEL OF ENVIRONMENTAL IMPACT ON HUNTINGTON'S DISEASE REVEALS GENOMIC INSTABILITY DURING REPROGRAMMING

Andrew M. Tidball[1], Asad A. Aboud[1], Reed Chamberlin[2], Kevin K. Kumar[1], Mihir V. Odak[1], Bryan E. Cawthon[1], Kevin C. Ess[1], M. Diana Neely[1], Aaron B. Bowman[1]

[1]Neurology, Vanderbilt University, Nashville, TN, United States, [2]Genetics Associates Inc., Nashville, TN, United States

Large kindred studies have shown that environmental factors account for a large amount of variability in Huntington's disease (HD) age at onset. Our lab has generated human induced pluripotent stem cell (hiPSC) lines from control subjects and patients with Huntington's disease using episomal-vector based reprogramming methods. We have validated independent lines from each of 4 controls and 4 HD patients to confirm loss of the reprogramming vectors (PCR), normal genomic structure (karyotyping), conformity of microarray data to known hiPSC profiles (pluritest), and expression of pluripotency genes (qRT-PCR and immunostaining). During our stringent process of validating the quality of our lines, we found a statistically significant increase in the propensity for karyotypic abnormalities in lines generated from patients with HD versus controls. A large majority of the abnormalities we have seen are common to human pluripotent cell lines including trisomy 12 and i(20)(q10), but we also see inversions, translocations, and deletions not typical to these cells. The abnormalities were not accounted for by the genomic integrity of the fibroblasts used to generate the iPSCs. We use the Yamanaka et al (Kyoto University) published reprogramming protocol that includes a p53 shRNA, known to decrease genomic integrity during reprogramming. We are currently reprogramming the same cell lines without the p53 shRNA to test for a disease-dependent effect on the rate of karyotypic abnormalities.
We have also differentiated our hiPSCs into early striatal neural progenitors adapting methods developed by the Studer (Sloan Kettering Institute) and Zhang (University of Wisconsin) labs. Using a recombinant protein-free small molecule based protocol, we can differentiate cultures >90 % PAX6+/FOXG1+/ISL1+ confirmed by immunostain-

ing and quantitative RT-PCR from both control and HD hiPSCs. We are currently exploring the toxicological profiles of pathologically-relevant toxicants (heavy metals and pesticides) on the striatial neural progenitors differentiated from our control and HD hiPSCs as well as lines from individuals with mutations to the PARK2 gene. Increased sensitivity to a particular neurotoxicant provides evidence for a possible disease x environment interaction and permits future mechanistic studies examining toxicant mode-of-action and how it relates to HD pathology. In addition, we will also perform a meta-analysis comparing this study to a parallel study in floor plate neural progenitors generated from the same hiPSC lines treated with the same toxicants (See poster Neely et al).

INDUCED PLURIPOTENT STEM CELLS REDUCE AIRWAY HYPERRESPONSIVENESS AND ALLERGIC REACTION IN SENSITIZED MICE

Shih-Jie Chou[1], Shih-Hwa Chiou[2]
[1]Pharmacology NYMU, Taipei, Taiwan, [2]Department of Medical Research & Education, Taipei Veterans General Hospital, Taipei, Taipei, Taiwan

B**ackground:** Allergic disorders have increased substantially in recent years. Asthma is characterized by airway damage and remodeling. Induced pluripotent stem cells (iPSCs) are embryonic-like cells derived from adult somatic cells by transduction of defined transcription factors. These cells have potential for multi-lineage differentiation and provide a resource for stem cell-based therapies. However, the therapeutic potential of iPSCs in allergic diseases and airway hyperresponsivenesss has not been investigated.**Objective:** The aim of this study was to evaluate the effect of iPSC transplantation on allergic reaction and airway hyperresponsiveness in a murine asthma model.**Methods:** BALB/c mice were sensitized with alum-adsorbed ovalbumin (OVA) and then challenged with aerosolized OVA. PBS or iPSCs were then intravenously injected after inhalation. Serum allergen-specific antibody levels, airway hyperresponsiveness, and cytokine production in spleen cells and bronchoalveolar lavage fluid (BALF) were then examined.**Results:** Treatment with iPSCs effectively suppressed both Th1 and Th2 antibody responses, which was characterized by reduction in serum allergen-specific IgE, IgG, IgG1, and IgG2a levels as well as in interleukin (IL)-5 and interferon-γ levels, and increased secretion of IL-10 in BALF and in OVA-incubated splenocytes. In addition, transplantation of iPSCs also significantly attenuated allergic airway hyperresponsiveness.**Conclusion:** Administration of iPSCs not only inhibited Th1 inflammatory responses but also had therapeutic effects on systemic allergic responses and airway hyperresponsiveness. We conclude that iPSC transplantation is a potential modality for treating allergic reactions and bronchial asthma.

USING INDUCED PLURIPOTENT STEM CELL TECHNOLOGY TO MODEL IDIOPATHIC PULMONARY FIBROSIS

Daniel Sivalingam[1], **Preethi Vijayaraj**[1], Katherine Chung[1], Saravanan Karumbayaram[2], Zoran Galic[2], Brigitte Gomperts[1]
[A]Department of Pediatrics, [1]University of California Los Angeles, Los Angeles, CA, United States

Idiopathic pulmonary fibrosis (IPF) is a debilitating disease that is characterized by chronic, progressive, irreversible fibrosis of the lung interstitium. There is no treatment for this devastating disease except lung transplantation. Our scientific understanding of the biology and pathogenesis of IPF is severely lacking. It is likely the result of a complex interplay of genes and environment. Previous work has identified that the loss of lung epithelial cells together with the proliferation of fibroblasts that grow in their place is a major hallmark of IPF. It is unknown however whether the fibroblasts are causing the “die off” of lung epithelium or if the “die off” is caused by another mechanism and triggers the hyperproliferation of fibroblasts. These fibroblasts accumulate as foci that lay down excessive extracelluar matrix, causing excessive tissue remodeling, increasing the stiffness of the lungs thereby making it difficult for gaseous exchange. We believe that in studying the complex interplay between these two cells type that we may gain a great deal of insight into the pathogenesis of IPF and its progression. The most widely used bleomycin rodent model to study IPF results in fibrosis that is self-resolving, and therefore is not a relevant model of IPF. Induced pluripotent stem cells (iPSC) have been used to model other complex diseases including Alzheimer’s disease and Duchenne Muscular Dystrophy, where genes and environment play a role in disease pathogenesis; however, iPSC have not yet been used to model IPF or any other fibrotic disorder.
Our approach to advance our understanding of IPF is to utilize cellular reprogramming to model IPF in combination with a thorough genetic analysis of the disease. Our approach utilizes healthy donor and IPF patient-specific lung and skin tissue to generate induced pluripotent stem cells (iPSC) using the traditional four transcription factors.. We confirmed pluripotency of the iPSC lines by teratoma formation and immunofluorescence for pluripotency markers. In addition, all iPSC lines were found to be karyotypically normal.
Cells re-derived from spontaneous differentiation of iPSC’s were enriched for fibroblasts and the identity of the cells were confirmed using fibroblast / mesenchymal markers like CD44 and vimentin. We have successfully re-differentiated the iPSC’s from two IPF and control lines into fibroblasts. Remarkably, the re-derived fibroblasts from the IPF patient samples spontaneously generated fibrotic foci that were positive for a-smooth muscle actin and laid out excessive extracellular matrix as seen from trichrome staining. We are currently experimenting with culture conditions to replicate α-smooth muscle actin-expressing fibrotic foci in other IPF samples.
We are also generating alveolar type I and type II cells from the iPSC’s in order to be able to co-culture the epithelial and fibroblast cells to identify interactions between the cell types that could accentuate the phenotype in a dish. To this end, we successfully differentiated iPSC into definitive endoderm with 70% of cells expressing CXCR4 and generated anterior foregut endoderm with expression of TBX1 and PAX9. We are now developing methods to expand the lung bud Nkx2.1+ pool of cells to create lung epithelial progenitors.
Following the generation of a reproducible disease model, our next approaches are to use the model as a drug-screening platform and to gain further insights into the molecular mechanisms of the disease.

W-2151

GENERATION OF INDUCED PLURIPOTENT STEM CELLS WITHOUT SUPPRESSION OF p53

Nelson F. Lizier, Irina Kerkis
Genetics, Butantan Institute, Sao Paulo, Brazil

Induced pluripotent stem (iPS) cells appeared as an alternative to embryonic stem (ES) cell, which allowed to overcome ethical problems of embryo destruction and to obtain patient matched pluripotent stem cells for the future therapies. Our group isolated a unique neural crest-derived population of immature dental pulp stem cells (IDPSC) widely multipotent, not tumorigenic, which maintain their ‘‘stemness’’ for several serial passages in vitro. Here, we used IDPSC as an alternative source for iPS cells. IDPSC is a very attractive cell type that can be easily isolated from an assessable, privileged and non-painful source. Using four Yamanaka’s factors we easily derived iPS cells from IDPSC, which were named for IDPSC-iPSC. Reprogramming of IDPSC occurred under feeder-free condition, making simple pluripotent colony harvest and avoiding future problem of zoonosis. Such reprogrammed cells present all characteristics of human ES cells especially in respect of differentiation capacity. IDPSC-iPSC generated teratomas into nude mice demonstrating wide range of differentiated tissues. It was reported that suppression of p53 gene increase efficiency of reprogramming suggesting its use as an improvement tool. IDPSC strongly express p53, however they showed high reprogramming efficiency (2.8%). The suppression of p53 is dangerous because iPS cells, which may carry genetic aberration, but showing normal iPS cells morphology can be obtained. Thus IDPSC derived iPS

cells present advantageous cell type for future therapies since they maintain the expression of p53 suggesting that IDPSC-iPSC could be safer for application in stem cells therapies.

CHARACTERIZATION OF iPS CELLS AND HEMATOPOIETIC CELLS FROM AN ICF SYNDROME TYPE2 PATIENT

Yutaka Yasui[1], Makoto Otsu[2], **Shin Kaneko**[1]

[1]Center for iPS cell Research and Application, Kyoto University, Kyoto, Japan, [2]Stem Cell Bank, Institute of Medical Science, The University of Tokyo, Tokyo, Japan

ICF syndrome is an extremely rare autosomal recessive disorder characterized by symptoms of immunodeficiency, chromosomal instability, and face deformity caused by DNA methylation abnormality. Defect of humoral immunity such as B lymphopenia with hypo γ-globulinemia is commonest immunodeficiency of the syndrome, followed by cellular immunodeficiency due to T- and/or NK lymphocyte dysfunction. Such combined immunodeficiencies frequently cause fatal opportunistic infections. DNMT3B gene mutation is known as only cause of ICF syndrome type I (ICF1). Recently, ZBTB24 gene was identified as a responsible gene of ICF syndrome type 2 (ICF2). We have established induced pluripotent stem (iPS) cells from a 40-year-old ICF2 male patient to clarify ZBTB24 function in hemato/lymphopoietic differentiation from induced pluripotent stem (iPS) cells.
iPS cell clones of an ICF2 syndrome patient were established from peripheral blood mononuclear cells (PBMC) by a sendai viral vector containing yamanaka-4-factors. Differentiation potential of the ICF2 iPS cells into hemato/lymphopoietic cell lineage was determined by co-cultivation method with suitable stromal cell. DNA methylation status at several hematopoietic stages was also determined.
Induction efficiency of ICF2 iPS cells by sendai-viral vector was equal to that of healthy volunteer's. Truncate mutation of ZBTB24 was confirmed in PBMC and iPS cells of the patient, but the specific chromosome aberration was detected only in PBMC. Though genomic DNA of ICF2 iPS cells were confirmed to be hypomethylated, their proliferation and teratomagenesis potentials were not different to normal iPS cells, but showed decreased sensitivity to radiation induced cell death. When they were differentiated into hematopoietic lineage, smaller number of hematopoietic stem cells (HSCs) can be obtained from ICF2-iPSCs. When they were stimulated by hematopoietic cytokines, large number of ICF2 HSCs stayed in G0 phase. Those results may suggest cell cycle associated role of ZBTB24 in hematopoietic differentiation.
Further cellular and molecular profiles of ICF2 iPS cells and their hemato/lymphopoietic derivatives will be discussed in the presentation.

The advent of induced pluripotent stem cell (iPSC) technology has raised the possibility that patient-specific human iPSCs (hiPSCs) could become a renewable source of autologous cells for cell therapy without the concern for immune rejection.. However, the immunogenicity of cells derived from hiPSCs has never been examined. To rigorously address this issue, we optimized a humanized mouse model (denoted Hu-mice) reconstituted with functional hu-

man immune systems, which can mount vigorous T-dependent immune responses to human cell transplants. We demonstrate that these Hu-mice can effectively reject tissues derived from allogenic human embryonic stem cells (hESCs). By deriving integration-free hiPSCs autologous to the human immune system reconstituted in Hu-mice, we evaluated the immunogenicity of cells derived from hiPSCs with both teratomas assay and in vitro differentiated cells. Our findings indicate that different tissues derived from hiPSCs exhibit differential immunogenicity to the autologous human immune system.

THE ACQUISITION OF SOMATIC MUTATIONS IN HUMAN INDUCED PLURIPOTENT STEM CELLS

Athurva Gore[1], Rui Liu[1], Athanasia Panopoulos[2], Ho-Lim Fung[1], Juan Carlos Izpisua Belmonte[2], Kun Zhang[1]
[1]Department of Bioengineering, University of California - San Diego, La Jolla, CA, United States, [2]Gene Expression Laboratory, Salk Institute for Biological Studies, La Jolla, CA, United States

Defined transcription factors can induce epigenetic reprogramming of adult mammalian cells into induced pluripotent stem cells (iPSCs). Recent studies have revealed that iPSC lines contain fixed point mutations after the process of reprogramming. However, the source of and mechanism behind these reprogramming-associated mutations remains unclear. It is unknown if mutations occur during the reprogramming process or are inherited from culture mutations in the progenitor cell population. Here we characterize in detail the origin of these mutations using a combination of whole-genome sequencing and targeted exome sequencing approaches. Using whole-genome sequencing data generated from small fractions of newly reprogrammed iPSC colonies, their three resultant iPSC lines, and their original progenitor cell line, we show that two-thirds of reprogramming-associated mutations pre-exist at low frequency in progenitor cells. We additionally demonstrate that pre-existing mutations and novel line-specific mutations are enriched for separate sets of epigenetic markers. We also show through repeated subcloning and targeted exome sequencing of three low-passage iPSC lines and one embryonic stem cell (ESC) line that iPSC genomes are relatively stable and uniform at the point mutation level during short-term culture, and that clonal expansion of single iPSCs does not inherently introduce mutations. Taken together, these results indicate that most iPSC mutations arise due to the culture of progenitor cells, and cannot be avoided using alternate reprogramming techniques. These results demonstrate the importance of genomic characterization of iPSCs prior to either in vitro or in vivo usage. Our findings will lead to a greater understanding of the origin of reprogramming-associated point mutations and will aid in the development of safe iPSCs for clinical use.

PURIFIED DISTAL LUNG ALVEOLAR EPITHELIUM DERIVED FROM HUMAN INDUCED PLURIPOTENT STEM CELLS REPOPULATE DECELLULARIZED LUNG SCAFFOLD

Mahboobe Ghaedi, Laura E. Niklason
Department of Anesthesia and Biomedical Engineering, Yale University, New Haven, CT, United States

It is postulated that the use of induced pluripotent stem (iPS) cells may be the most effective strategy to develop patient-specific respiratory epithelial cells that may be valuable in lung-related cell therapy and lung tissue engineering. To explore whether lung tissue can be regenerated in vitro, a relatively homogeneous population of alveolar epithelial type II (AETII) and type I cells (AETI) was generated from human iPS cells which had phenotypic properties similar to mature human alveolar type II and type I cells. Up to 97 % of cells were positive for surfactant protein C, 95% for Mucin-1, 93% positive for surfactant protein B, and the vast majority (89%) of the cells expressed the epithelial marker CD54. Additionally, more than 90% of AETI were positive for the type I marker, T1α and Caveolin-1. Acellular lung matrices were prepared by treating whole rat or human adult lungs with decellularization agents, and alveolar cells derived from human iPS cells were cultured on the acellular rat or human lung matrices in a lung bioreactor culture system. Under appropriate culture conditions, these progenitor cells adhered to and proliferated within a 3D lung tissue scaffold, displayed hierarchical organization within the matrix, and displayed multiple markers of differentiated pulmonary epithelium

RESIDUAL UNDIFFERENTIATED CELLS DURING DIFFERENTIATION OF INDUCED PLURIPOTENT STEM CELL IN VITRO AND IN VIVO

Wei Fu[1], Shujun Wang[2], Wenjie Zhang[2], Guangdong Zhou[2], Wei Liu[2], Yilin Cao[2]
[1]Department of Pediatric Thoracic and Cardiovascular Surgery, Shanghai Children's Medical Center, Shanghai Jiao Tong Univ Sch of Medicine, Shanghai, China, [2]Shanghai Jiao Tong Univ Sch of Medicine, Shanghai, China

Induced pluripotent stem (iPS) cells are a potential cell source for regenerative medicine. However, the tumorigenicity of iPS cells is a big concern for clinical application. In addition to the genetic manipulation of the reprogramming process and the greater risk of tumor formation, it is unclear if iPS cells with normal development potential are still tumorigenic. Here we investigated three mouse iPS cell lines, including one line that is able to generate full-term mice via tetraploid blastocyst complementation. We found that a small number of undifferentiated iPS cells could be steadily isolated and expanded following long-term differentiation of cells *in vitro* or *in vivo*. The residual undifferentiated iPS cells could be expanded and re-differentiated, and undifferentiated pluripotent stem cells could again be isolated after further rounds of differentiation, suggesting that residual undifferentiated iPS cells could not be eliminated by extended cell differentiation. The residual undifferentiated cells could form teratomas *in vivo*, indicating that they are a potential tumorigenic risk during transplantation. These findings prompt us to reconsider the strategies for solving the tumorigenic problem of iPS cells, not only focusing on improving the reprogramming process.

W-2157

A HIGHLY REGERATIVE ANIMAL, PTYCHODERA FLAVA, REVEALS A ROLE IN REGENERATION FOR EVOLUTIONARY RELATIVES OF OCT4 AND NANOG.

Keith Weiser, Tom Humphreys
Institute for Biogenesis Research, University of Hawaii, Honolulu, HI, United States

Oct4 and Nanog are well known for their roles in maintenance and induction of a pluripotent state. In vertebrates, this activity is restricted to cells of the inner cell mass and primordial germ cells. These genes are also able to initiate a state of induced pluripotency in mature cells. We have identified candidate orthologs of Oct4 and Nanog in a highly regenerative hemichordate marine animal, *Ptychodera flava*. *P. flava* is notable for its ability to completely regenerate missing anterior and posterior body axes on bisection. No bilateral animal with a head and tail capable of extensive regeneration is more closely related to humans. The Oct4 candidate ortholog, PfPou3f3/4 shares 75% amino acid identity with human Oct4 within the conserved homeodomain and Pou domains. Allowing for conservative substitutions, the similarity is 85% over 127 amino acids and PfPou3f3/4 is the *P. flava* gene most similar to Oct4 and homologs from other species. Likewise, PfMsxlx is the P. flava gene most similar to vertebrate Nanogs. *In situ* hybridization of regenerating *P. flava* reveals expression of PfPou3f3/4 and PfMsxlx proximal to the blastema during regeneration and no expression in uninjured animals. The regenerating blastema presumably contains the pluripotent cells that will regenerate the missing body half and expression of orthologs of vertebrate pluripotency-associated genes may indicate a role for these genes in inducing or maintaining a pluripotent state during regeneration. PfPou3f3/4 is able to maintain expression of several Oct4-driven stem cell genes such as Zfp42 (Rex1), Fgf4, and Klf4 in mouse ES cells in the absence of Oct4 expression. Like Oct4, over-expression of PfPou3f3/4 reduces Wnt signaling in p19 embryonic carcinoma cells. Due to the sequence similarity and functional similarities, we believe that PfPou3f3/4 is an evolutionary relative of Oct4. We further hypothesize that PfPou3f3/4 has a function in reprogrammg cells to a multipotent or pluripotent state in regeneration. This may indicate that the reprogramming activity of pluripotency genes represents vestiges of a regenerative program that has been lost in vertebrates.

W-2158

REPROGRAMMING TO PLURIPOTENCY CAN CONCEAL SOMATIC CELL CHROMOSOMAL INSTABILITY

Liviu Malureanu, Masakazu Hamada, Tobias Wijshake, Wei Zhou, Jan van Deursen
Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, United States

One of the concerns regarding the safe use of induced pluripotent stem cells (iPSCs) in therapeutic applications is loss of genomic integrity, a hallmark of various human conditions and diseases, including cancer. Structural chromosome defects such as short telomeres and double-strand breaks are known to limit reprogramming of somatic cells into iPSCs. Reprogrammed cells have successfully been generated from somatic cells that undergo stable inheritance of an abnormal number of chromosomes, such as Down syndrome. This implies that aneuploidy (an abnormal number of chromosomes) is not a barrier to reprogramming. However, the extent to which defects that promote the continuous reshuffling of whole chromosomes during mitosis, a condition referred to as whole chromosome instability (W-CIN), interfere with efficient reprogramming of somatic cells is unknown.
To begin to address the impact of numerical chromosome instability on stem cells we examined the impact of two distinct W-CIN gene defects on somatic cell reprogramming.
We selected MEFs derived from *BubR1* (*BubR1*$^{H/H}$) and *RanBP2* hypomorphic (*RanBP2*$^{-/H}$) mutant mice for our studies because their aneuploidy rates are similar (36% and 33% aneuploid cells at passage 5, respectively) although the aneuploidization is driven by entirely different mechanisms. To induce reprogramming to pluripotency, Oct-3/4, Sox2, and Klf4 expression constructs were introduced in P5 wild-type, *BubR1*$^{H/H}$, and *RanBP2*$^{-/H}$ MEFs by retroviral transduction.
Here we demonstrate that MEFs with W-CIN gene defects fully reprogram to iPSCs with similar efficiency as wild-type MEFs but with highly contrasting outcomes on chromosome number integrity and stability: *BubR1* hypomorphic iPSC clones preferentially originate from aneuploid MEFs, while *RanBP2* hypomorphic iPSC clones preferentially stem from MEFs with normal diploid chromosome numbers, indicating that aneuploid cells can be selected for or against during reprogramming depending on the genetic defect driving the chromosome number instability. The observation that *BubR1*$^{H/H}$ aneuploid MEFs preferentially dedifferentiate raises the possibility that BubR1 might be a key component of a surveillance pathway that prevents aneuploid cells from reprogramming. Knowing that BubR1 levels decrease with aging, we hypothesize that reprogramming of somatic cells from elderly individuals into karyotypically normal and stable iPSCs may be particularly challenging. Our data uncovered the fascinating concept that a W-CIN gene defect (*RanBP2* hypomorphism) responsible for severe aneuploidization in somatic cells can become dormant upon reprogramming, indicating that testing of both iPSCs and the iPSC-founding cells for chromosome number instability will be necessary for the safe application of iPSC technology in regenerative medicine.

THE DEVELOPMENT OF SMALL SCALE SINGLE-USE BIOREACTOR SYSTEM FOR HUMAN INDUCED PRULIPOTENT STEM CELL

Masanori WADA[1], Katsuhisa MATSUURA[2], Yoichi ISHIKAWA[1], Tatsuya SHIMIZU[2], Teruo OKANO[2]
[1]R and D section, ABLE Corporation, Tokyo, Japan, [2]Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Tokyo, Japan

[Introduction]
Induced pluripotent stem (iPS) cells are promising cell sources for regenerative medicine. The stirred suspension culture using a bioreactor system is an efficient method for the large scale expansion of human iPS cells. On the basis of our hypothesis that a low share stress and the uniform medium flow in a vessel are important for the suspension culture of human iPS cells, we have developed the bioreactor system which are capable of the stirred suspension culture of the inoculated single iPS cells in the aggregates condition. This system is also capable of operating eight 100mL bioreactors simultaneously, and controlling culture condition individually.
[Material and method]

At first the stirrer designs including pitched 6 blade impeller and delta shape paddle impeller were compared in terms of the hiPSC growth in suspension culture. The optical DO sensor and the small pH electrode were used in order to suppress the turbulent flow inside a reactor. The single cell suspension were prepared from 2D on-feeder culture and inoculated into 100mL bioreactor (2x10^5cells/mL). The cell aggregates were collected after the stirred suspension culture for 4 days, and dissociated into the single cells by using Accumax. Then the obtained single cells were re-inoculated into the bioreactor, and stirred suspension culture was performed up to 5 passages. The number of cells, and the number and size of aggregates were measured in every passage. The undifferentiated property of the expanded iPS cells was evaluated with the flow cytometric analysis.
[Results and discussion]
Although the culture using 6 pitched blade impeller failed to promote the aggregate formation and expand human iPS cells, the culture using the delta shape paddle impeller enabled to create a lot of aggregates 200 to 300 micrometer diameter in the cultivation for 4 days. Furthermore the number of cells increased 5 times (1x10^8cells) to the number of inoculated cells. The similar cell growth rate was observed for 4 days in each culture after the passage (1-5 passages). When obtained cell suspension was inoculated on the culture dish, hiPS cell specific colony formation was shown. The flow cytometric analysis revealed that more than 95% of population holded undifferentiated ability in all the passages. Collectively, we established the methods for the expansion of human iPS cells with undifferentiated state.

GENERATION OF NEURONS FOR THE STUDY OF BIPOLAR DISORDER OF OLD ORDER AMISH PEDIGREE

Kwi Hye Kim[1], Rosamund Smith[2], Rachelle J. Galvin[3], Laurence Daheron[4], Steven M. Paul[5], Kalpana M. Merchant[1]
[A]Tailored Therapeutics-Neuroscience, [B]Regenerative Biology, [C]Quantitative Biology, [1]Eli Lilly and Company, Indianapolis, IN, United States, [2]Havard Stem Cell Institute, Harvard University, Cambridge, MA, United States, [3]Weill Cornell Medical College, New York, NY, United States

Bipolar disorder (BPD), also known as manic-depression, is a brain disorder manifested as unusual shifts in energy, activity level, and mood. According to the World Health Organization, bipolar disorder is the 7th leading cause of non-fatal burden in the world. Patients often show their first symptoms during late teens or early adult ages. The disease severely hinders their ability to perform daily tasks. Available treatments produce only partial responses and none cure the disease.
It is known that BPD runs in families, suggesting a role of genetic factors. However, the molecular mechanism(s) leading to BPD is poorly understood. To develop a cellular model that enables studies of molecular and functional mechanisms associated with BPD, fibroblasts from Old Order Amish pedigrees with high incidence of BPD and the emerging technology of induced pluripotent stem cells (iPSCs) have been utilized.
Fibroblasts from twelve individuals, representing six patients and a corresponding unaffected sibling, have been reprogrammed to iPSCs. Reprogrammed iPSCs have been characterized for their pluripotency. Established iPSCs were differentiated into neuroprogenitors and to neurons. Their differentiation states have been characterized by immunocytochemical analysis and quantitative real time polymerase reaction. The iPSC derived neurons here will be the foundation to study molecular mechanism of BPD in an *in vitro* model system.

Cambridge, MA, United States, [5]Massachusetts General Hospital, Boston, MA, United States, [6]Harvard University, Cambridge, MA, United States, [7]Mount Sinai School of Medicine, Cambridge, MA, United States, [8]Broad Institute/ Massachusetts General Hospital, Boston, MA, United States

Bipolar disorder represents a significant burden to patients, families and society. Despite evidence for high heritability, the underlying etiology and pathophysiology of this psychiatric disorder remains poorly understood. The genetic landscape of psychiatric disorders is complex and existing approaches that model changes in small numbers of genes across development are not well suited to capture the multiple genetic factors interacting in an individual to cause disease risk. Advances in stem cell biology allow one to capture this genetic complexity in induced pluripotent cells (iPSCs) derived from patient fibroblasts and then differentiate them into disease-relevant cell types. This approach will enable the investigation of functional variation that contributes to risk for psychiatric disorders and the development of phenotype-based assays for use in high throughput small molecule and RNAi screens. To begin to develop an iPSC based platform to investigate psychiatric disorders, we reprogrammed a family of fibroblasts from a larger kindred segregating several forms of psychiatric illness including Type I bipolar disorder. We anticipated reprogramming a family would help control for phenotypic variability between individuals due to background heterogeneity. This family consisted of two healthy parents and their two bipolar sons. Our genetic analysis of these fibroblasts showed there were no gross genetic lesions. Subsequently, we derived 3 independent iPSC lines from each individual. Based on several criteria, including gene expression analysis (Pluritest) and teratoma formation, all 12 iPSC lines were shown to be pluripotent. From each iPSC line we used adherent monolayer neural induction cultures and fluorescence activated cell sorting to establish comparable populations of proliferative neural progenitor cell lines (NPCs). While we were able to establish three independent NPC lines from each of the unaffected parents, we were only able to establish NPCs from one out of three lines for each of the sons with bipolar disorder. Furthermore, the NPC lines we were able to establish from the bipolar sons showed decreased proliferation as assayed by BrdU incorporation. While each of the established NPC lines was capable of differentiating into neurons as defined by immunocytochemistry using lineage-specific markers, NPC lines derived from both bipolar disorder sons exhibited decreased numbers of neurons. We used several quantitative gene expression approaches to determine if the differences in establishment of NPCs were due to differences in differentiation capacity. We were unable to find a correlation between a cell line's ability to generate NPCs and a decrease in general differentiation capacity or neural differentiation capacity. Finally, we were able to rescue the proliferation defect of the bipolar disorder NPCs using a GSK3 small molecule inhibitor capable of activating the WNT pathway _ a known target of the mood stabilizer, lithium, which is used clinically to treat bipolar disorder. Taken together, our results suggest that these iPSC derived NPCs from bipolar individuals have a neurodevelopmental defect in the establishment or maintenance of iPSC-derived NPCs. We anticipate these approaches will provide novel insights into the etiology of these complex psychiatric disorders and paths toward novel targeted therapeutics for their treatment.

HUMAN IPSC-DERIVED MOTOR NEURONS, AN ATTRACTIVE MODEL FOR BOTULINUM NEUROTOXIN DRUG DISCOVERY

Morgan A. Hrones, Dejan Caglic, Tobin J. Dickerson
Chemistry, The Scripps Research Institute, La Jolla, CA, United States

Botulinum neurotoxin A, (BoNT/A) the causative agents for botulism, is documented as the most toxic proteins known to man, with a lethal dose of 1 ng/kg of body weight. Produced by the bacterium *Clostridium botulinum*, BoNT/A is currently regarded as one of the top six agents for bioterrorist use due to its long lasting effects of flaccid paralysis, relative ease in production, and ability to be aerosolized for mass intoxication in locations containing dense populations. In order to further our overall understanding behind this intracellular mechanism and to increase our accuracy with leads for future intracellular BoNT/A inhibitors, stem cells are an ideal model for BoNT/A intoxication studies. Stem cells, unlike other cellular models, produce large quantities of motor neurons and use quantities of BoNT representative of *in vivo* conditions. Thus, a suitable reporter has been prepared for detection of

BoNT/A intracellular activity containing the SNAP25 protein, the native substrate for BoNT/A, and two fluorescent proteins. These two fluorescent proteins allow the detection of BoNT intracellular activity via a change in fluorescence resonance energy transfer (FRET). Preliminary data has shown that two more traditionally used fluorescent proteins, namely CFP and YFP, are somewhat functional in cell lines, however, the low efficiency of FRET poses an issue for accurate detection. Thus, CFP and YFP have been exchanged with Clover and mRuby2, since this novel fluorescent pair has been documented to have higher FRET efficiency and dynamic range. After confirming the functionality of our reporter in a less sensitive model, namely a Neuro2A cell line, transfection of human induced pluripotent stem cells (hiPSCs) with the newly made construct allows us to engineer stem cells that give rise to motor neurons stably expressing our reporter of interest. Observing the actual cleavage of SNAP25 ultimately enables us to conduct small molecule screening campaigns with more accurate leads for future drug development that possess the ability to block intracellular activity of BoNT/A.

W-2165

AP-1 TRANSCRIPTION FACTOR JDP2 POTENCIATES THE GENERATION OF MEDULLOBLASTOMA CANCER STEM CELLS FROM INDUCED PLURIPOTENT STEM CELLS

Kazushige K. Yokoyama[1], Chia-Chen Ku[1], Jian-Yi Li[1], Nein-Chi Wu[1], Yu-Ting Yen[1], Shyh-Shin Chiou[2], Yukio Nakamura[3], Shigeo Saito[4]

[1]Graduate Institute of Medicine, Koahsiung Medical University, Kaohsiung, Taiwan, [2]Pediatrics, Koahsiung Medical University Hospital, Kaohsiung, Taiwan, [3]Cell Engineering Division, RIKEN BRC, Tsukuba, Japan, [4]Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

Transcription factor Jun dimerization protein (JDP2) plays roles in cell cycle regulation, cellular senescence, nuclear reprogramming and oncogenesis through the epigenetic control involved in cascades of $p19^{Arf}$-Md-m2-p53-p21-cyclin/CDK or $p16^{Ink4a}$-cyclin/CDK-RB-E2F. Clinical studies of medulloblastomas indicate that JDP2 might be a tumor suppressor gene candidate because normal granule cells express significant levels of JDP2, whereas cancer cells do not. Thus, we generated three different induced pluripotent stem cells (iPSCs) from human medduloblastoma cancer cells (DAOY1) using Lenti-virus encoded standard 4 factors (4F; Oct4, Klf4, Sox2 and c-Myc) and 2 factors (2F; Oct4 and JDP2). The original DAOY1 expressed three standard stemness genes like Oct4, Sox2 and Nanog, but did not show the alkaline phosphatase activity. By contrast, iPSCs expressed stemness genes and demonstrated the alkaline phosphatase activity. Moreover, we found that iPSCs enhanced the tumor progression as compared with DAOY1 in SCID mice. These results indicate that JDP2 is highly possible to play a critical role of tumor potentiating function of iPSCs to generate the cancer stem cells. We also found the role of JDP2 is concerned the signaling of Wnt signals such as the genes encoding LEF1 (lymphoid enhancer binding protein), TCF3. The cross talk of Wnt signal and LIF/JAK-STAT3-Oct4 will be critical for generation of cancer stem cells from medduloblastoma iPS cells.

W-2166

SANGER HUMAN INDUCED PLURIPOTENT STEM CELLS REPRESENT A DISTINCT PLURIPOTENT STATE WITH BIOLOGICAL CHARACTERISTICS SIMILAR TO MOUSE EMBRYONIC STEM CELLS

David J. Ryan, Wei Wang, Jian Yang, Fengtang Yang, Beiyuan Fu, Pentao Liu
Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Introduction: From rodent studies it is clear that pluripotency is a dynamic state. Preimplantation and postimplantation embryos yield two distinct pluripotent states, naïve and primed respectively. To date, embryonic stem cells with characteristics of ground state pluripotency have not been derived from human embryos. Human embryonic stem cells seem to represent a pluripotent state more akin to the mouse primed state. Does the naïve state exist in non-rodent species? If so, then is the naïve state a transient metastable entity? How can we identify and capture this entity in humans? We sought to use cellular reprogramming as a means to interrogate this ques-

tion.Methods: Our published 6 factor reprogramming platform was used to generate Sanger Human induced pluripotent stem cells (SH-iPSCs) from human dermal fibroblasts. Reprogramming factors (OCT4, c-MYC, SOX2, KLF4, LRH1, and RARG) were delivered using episomal vectors or piggyBac mediated transposition of doxycycline inducible constructs. Generated lines were characterized for pluripotency gene / protein expression, loss of reprogramming plasmids / silencing of transgenes and *in vitro / vivo* differentiation. Parameters supportive of naïve pluripotency in mouse including X chromosome reactivation, immune privilege and biallelic nanog were tested.Results: Karyotypically normal, LIF dependent SH-iPSCs were produced which expressed the key pluripotency genes, had no detectable expression of exogenous factors and were competent for three germ layer differentiation. RNA FISH demonstrated two HPRT signals and no XIST cloud. Biallelic Nanog was also demonstrated on RNA FISH. During differentiation, reversibility was seen with appearance of XIST and loss of one HPRT signal. Expression profiling of X linked genes demonstrated dosage compensation during differentiation. Consistent with the immune privilege of the early embryo, SH-iPSCs had little MHC Class 1 expression suggesting a more immature phenotype.Conclusion: Sanger human induced pluripotent stem cells represent a distinct pluripotent state with properties similar to those of mouse embryonic stem cells. This cell type may be useful for studying early human development, including, the regulation of X chromosome inactivation during gastrulation.

MODELING CFC SYNDROME USING PATIENT-SPECIFIC IPS CELLS

Kyu-Min Han, Yong-Mahn Han
KAIST, Daejeon 305-701, Korea, Republic of

Cardio-Facio-Cuteneous (CFC) syndrome shows various kinds of early developmental defects, including craniofacial dysmorphology, cardiac problem, mental retardation, and short statue. Most of CFC syndromes have mutations in RAS-MAPK signaling, thereby resulting in elevated ERK activity. However, little is known about how elevated ERK signaling is related to the patient's phenotypes at the cellular level. Here, patient-specific iPSCs were generated from dermal fibroblasts of CFC patient carrying c.770A>G mutation on BRAF gene by ectopic expression of OCT4, SOX2, NANOG, and c-MYC. CFC-iPSCs expressed pluripotent markers at transcription and protein levels with normal karyotypes. As a result, we found that abnormal embryoid body maintenance in CFC-iPSCs might be caused by mislocalization of beta-catenin. CFC-iPSCs will be useful for studying the early developmental defects of CFC syndrome.

Epigenetic Memory of iPS Cells Helps Improve Differentiation Efficiency into Retinal Pigment Epithelium
Vaisakh Rajan, Janine Davis, Ruchi Sharma, Rafael Villasmil, Fang Hua, Qin Wan, Kiyoharu Miyagishima, Sheldon S. Miller, and Kapil Bharti
National Eye Institute, National Institutes of Health, Bethesda, MD
Retinal degenerations are one of the leading causes of blindness in the US. Several forms of retinal degenerative diseases are caused by developmental or functional defects in the retinal pigment epithelium (RPE), a polarized monolayer of cells located in the back of the human eye. RPE functions to maintain the health and integrity of retinal photoreceptors, thus maintaining vision. Stem cell technology provides the possibility of developing *in vitro* disease models, cell-based therapies, and platforms for drug screenings. RPE can be differentiated from pluripotent stem cells. However, the differentiation efficiency is low and varies between different stem cell lines. We have used combination of a developmentally guided protocol and the “epigenetic memory” of induced pluripotent stem (iPS) cells to significantly improve the efficiency of differentiation into RPE. To harness the full potential of “epi-

genetic memory", we generated iPS cells from primary human fetal RPE (hfRPE) using the four pluripotentency factors SOX2, OCT3/4, KLF4, and c-MYC. These iPS cells were differentiated into RPE-like cells using a developmentally guided protocol that modulates TGF, WNT, FGF, and Nodal pathways. Differentiation efficiency of iPS cells derived RPE was checked using immuno-labeling and FACS analysis of three RPE-specific markers PAX6, MITF and TYROSINASE. The three markers are expressed in all the cells suggesting a differentiation efficiency of up to 100%. Our preliminary analysis shows that RPE derived from hfRPE derived iPS cells closely resemble primary RPE at molecular and physiological levels. We are currently performing a thorough molecular and physiological authentication of these cells. In conclusion, we have developed a protocol that efficiently differentiates iPS cells into RPE. This protocol will provide the basis for developing improved disease models and effective therapies.

EFFECTS OF SOMATIC CELL OF ORIGIN ON NEURAL INDUCTION FROM HUMAN INDUCED PLURIPOTENT STEM CELLS

Gunnar Hargus[1], Marc Ehrlich[1], Marcos J. Arauzo-Bravo[2], Jeong Beom Kim[3], Tanja Kuhlmann[1], Hans R. Schöler[2], Holm Zaehres[2]

[1]Institute of Neuropathology, Univsersity of Münster, Münster, Germany, [2]Max Planck Institute for Molecular Biomedicine, Münster, Germany, [3]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

Epigenetic memory in induced pluripotent stem (iPS) cells in regard to their donor cell type of origin could lead to variations in their differentiation capacities. We have generated iPS cells from human neural stem cells (NSC iPSC) and human cord blood derived CD34+ hematopoietic stem cells (CD34+ iPSC) as well as fibroblasts (Fib iPSC) and evaluated their potential to differentiate into neural precursor cells and into more mature neural cell types (Hargus et al., 2010, PNAS).
We performed whole genome expression analysis on enriched populations of nestin-positive and sox1-positive neural precursor cells from NSC iPSC, CD34+ iPSC and Fib iPSC and carried out an analysis of neural marker expression in terminally differentiated cells. Here, we found that neuronal differentiation was comparable and not significantly different between iPSCs derived from different somatic cell sources (NSC iPSC: 31,9%; CD34+ iPSC: 30,2%; Fib iPSC: 28,4% βIII-tubulin-positive neurons over all cells). In addition, we determined methylation patterns of neural genes in iPSC and human ES cells to decipher epigenetic memories.
Our data indicate that epigenetic differences in human iPS cell lines generated of different donor cell type of origin (ectodermal neural versus mesodermal blood cells or fibroblasts) seem to have moderate impacts on neural precursor cell generation, but do not have a significant impact on their terminal neuronal differentiation potential.

W-2172

MODIFICATIONS IN THE EXPRESSION OF HDACS AND DNMTS IN HUMAN NEURAL STEM CELLS INDUCED BY REPROGRAMMING AND LOW OXYGEN TENSION

Ilona Szablowska-Gadomska, Martyna Podobinska, **Leonora Buzanska**
Mossakowski Med Res Ct, Warsaw, Poland

Modifications in the expression of HDACs and DNMTs in human neural stem cells induced by reprogramming and low oxygen tension

Ilona Szabłowska-Gadomska, Martyna Podobinska, Leonora Buzanska
NeuroRepair Department, Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland;
To better understanding the reprogramming and differentiation process in human neural stem cells we aimed to look at the mutual relationship between pluripotency regulatory network and epigenetic process at different oxygen conditions. Thus the expression of pluripotency genes, hypoxia inducible factors, histon deacetylases and DNA methyltransferases have been tested in HUCB-NSC (Human Umbilicar Cord Blood – Neural Stem Cell) line at diffrent developmental stages. Our previous data have shown that the low oxygen tension promote maintenance of undif-

ferentiated state of HUCB-NSC and is beneficial for their proliferation and activate Oct4 and Nanog genes in time of cultivation and developmental stage dependent manner. Cells incubated in all tested oxygen conditions expressed HIF 1 alpha and HIF 2 alpha, however expression of HIF 3 alpha was not detected. Elevated expression of HIF2α, but not HIF1α is correlated with the induction of pluripotency, but only after prolonged incubation of HUCB-NSC in low oxygen. It also enhanced neural commitment of HUCB-NSC as shown by elevated MAP2 accompanied by HIF1 expression. In this report genes involved in epigenetic modulations, such as HDAC1, HDAC2, DNMT3a and DMNT 3b, have been tested for their expression at different developmental stages of HUCB-NSC: in reprogrammed to pluripotency or kept in culture as neurally committed population. The induced pluripotent cells and neurally committed population have been both incubated in low oxygen tension condition. Our results show, that in neurally committed HUCB-NSC expression of HDAC2, DNMT3a and DMNT 3b was significantly lower than in pluripotent stem cells and ESC reference material. Induced pluripotent stem cells revealed significantly higher expression of two genes HDAC1 and HDAC2 as compared to ESC and differentiated cells. Our results did not indicated linear correlation between the expression of HDACs and DNMTs and cell developnental stages, however pluripotency regulatory network and epigenetic process at different oxygen conditions are highly interdependent.

GENERATION OF INDUCED PLURIPOTENT STEM CELLS FROM CHARCOT-MARIE-TOOTH TYPE 2F PATIENTS AND DIFFERENTIATION INTO NEURONAL CELLS

Ji-Yon Kim[1], Jin-Mo Park[2], Young-Bin Hong[2], Kyung-Ha Ryu[3], So-Youn Woo[1], Byung-Ok Choi[2]
[A]Microbiology, [B]Neurology, [C]Pediatrics, [1]Ewha womans university, school of medicine, Seoul, Korea, Republic of

Charcot-Marie-Tooth (CMT) disease is a genetically and clinically heterogenous disorder causing chronic distal motor and sensory neuropathy. CMT type 2F is caused by point mutations of heat shock protein beta-1 (HSPB1) gene and their disease mechanisms are not fully elucidated yet. To overcome limitations of handing human neuronal cells in vitro, we generated CMT2F-specific iPSCs and differentiated into neuronal cells. iPSCs from normal controls and patients showed characteristics of colony morphology and expressed stem cell markers such as Nanog and SSEA4, and alkaline phosphatase. To verify functional pluripotency of stem cells, iPSCs were randomly differentiated into three germ layer cells in vitro. Then, iPSCs were directly differentiated into neuronal cells with retinoic acid (RA), sonic hedgehog (Shh), brian-derived neurotrophic factor (BDNF) and glial cell-derived neurotrophic factor (GDNF). Here, we generated neurons derived from CMT2F-specific iPSCs for the first time which can be a prominent material to study disease phenotypes and drug screening.

MODELING HEREDITARY HEMOCHROMATOSIS USING INDUCED PLURIPOTENT STEM CELLS.

Andreia Gianotti Sommer[1], Cesar A. Sommer[1], David Nunes[2], Gustavo Mostoslavsky[1]
[A]Center for Regenerative Medicine (CReM), [B]Medicine, [1]Boston University School of Medicine, Boston, MA, United States

Mutations in the HFE gene underlie the pathogenesis of Hereditary Hemochromatosis (HH), the most common inherited liver disease. We employed our STEMCCA lentiviral reprogramming vector to derive iPSCs from several patients with HH carrying distinct HFE mutations. The iPSC lines expressed the pluripotency markers SSEA-4, Tra-1-60 and Tra-1-81, displayed a normal karyotype, and were capable of efficient differentiation into hepatocyte progenitors expressing albumin, AFP, HNF4a and the HH-related genes HFE and hepcidin. Notably, HH-iPSC derived hepatocyte progeny expressed lower levels of hepcidin compared to normal cells, providing a potential experimental platform to study the disease phenotype in vitro. Furthermore, we engineered and validated Transcription Activator-like Effector Nucleases (TALENs) targeting the HFE locus in order to generate gene-corrected HH-iPSC lines for both disease modeling and cell replacement therapies.

W-2175

EFFICIENT GENERATION OF EQUINE MOTOR NEURONS FROM INDUCED PLURIPOTENT STEM CELLS.

Ruchi Sharma[1], David Hay[2], Xavier Donadeu[1]

[1]Developmental Biology, The Roslin Institute and Royal (Dick) School of Veterinary Studies, Edinburgh, United Kingdom, [2]MRC Centre for Regenerative Medicine, University of Edinburgh, Edinburgh, United Kingdom

High fidelity models of neurogenesis are necessary to better understand mammalian development and disease. Equine motor neuron disease (EMND), comparable to the human disease, is currently untreatable and often results in euthanasia on ethical grounds. In contrast to humans, *in vitro* models of equine neurogenesis do not exist. Pluripotent stem cell populations have enormous potential in disease modelling given their ability to form derivatives of the three germ layers found in the developing embryo. While a promising notion, the isolation of equine embryonic stem cells has thus far proved elusive and therefore it has been necessary to explore other alternatives to generate pluripotent stem cell populations. Induced pluripotent stem cells (iPSCs) are generated by reprogramming somatic cells to an embryonic state. Therefore iPSCs represent an extremely valuable tool for modelling disease and organ toxicity, with enormous potential in veterinary medicine. In this study, we describe the generation of iPSCs from equine keratinocytes and their efficient and robust differentiation into motor neurons.
Skin biopsies from a 5-month old foal were used to derive keratinocyte cultures. These cells were then transduced with retroviral constructs coding for murine Oct-4, Sox-2, c-Myc and Klf-4 sequences, following the original Yamanaka protocol. Following transduction, tight cell colonies were generated that had sharp boundaries, stained positive for alkaline phosphatase and resembled previously reported human iPSCs. The reprogrammed cells were successfully maintained in feeder free and serum free conditions with LIF supplementation for 40 passages. Immunochemistry and qPCR analyses revealed the iPSCs lines expressed pluripotency markers expressed in equine embryonic stages including, Oct4, Sox2, SSEA1, Lin28, Nanog, Rex1, Tert and Dnmt3b. Equine iPSC*s* were able to form embryoid bodies and to differentiate into derivatives of the three germ layers *in vitro* as indicated by expression of lineage-specific markers including alpha-Fetoprotein (AFP) and Gata-4 (endodermal), Nestin and Neuron specific class III Beta Tubulin (Tubb3) (ectodermal), and vimentin and smooth muscle actin (mesodermal). Equine iPSCs were pluripotent *in vivo* as demonstrated by the formation of teratomas consisting of tissue derivatives of all three lineages such as bone, cartilage, pulmonary epithelium and mature neurons in SCID mice. Importantly, in addition to its ability for spontaneous differentiation, equine iPSCs were amenable to efficient and robust directed differentiation into neuronal tissue. Equine iPSCs were successfully induced to differentiate into neurospheres forming extensive neuronal projections and synapses which stained for neuronal markers including Tubb3, Map2, Synapsin1 and Choline acetyl transferase (ChAT). In addition, gene expression analysis with qPCR revealed expression of Foxg1, Pax6 and Nestin during induced neurogenesis, followed by up regulation of ISL1, a potent and specific inducer of motor neurons, during terminal differentiation. In conclusion, we report for the first time the generation of equine neurons in vitro, providing, also for the first time, demonstration of the potential of iPSCs in equine biomedicine. The ability to derive motor neurons *in vitro* opens the way for new and exciting applications in equine regenerative medicine and reveals highly conserved pathways of differentiation across species.

W-2176

GENERATION OF INDUCED PLURIPOTENT STEM CELLS (IPSC) FROM PATIENTS WITH FAMILIAL OSTEOCHONDRITIS DISSECANS (FOCD) TO LINK DEFECTIVE MATRIX ASSEMBLY WITH CARTILAGE INJURY

Maojia Xu[1], Georgina Shaw[1], Eva-Lena Stattin[2], Dick Heinegard[3], Alan Colman[4], Mary Murphy[1], Frank Barry[1]

*[1]Regenerative Medicine Institute (REMEDI), National University Ireland, Galway, Galway, Ireland, [2]Department of Medical Biosciences, Umeå University, Umeå, Sweden, [3]Department of Clinical Sciences Lund, Lund University, Lund, Sweden, [4]A*STAR Institute of Medical Biology, Singapore 138648, Singapore*

Background

Familial osteochondritis dissecans (FOCD) is an autosomal dominant connective tissue disorder characterised by disturbed chondro-skeletal development, disproportionate growth and deformation of the skeleton in affected family members. A recent study indicated that a missense mutation in the aggrecan C-type lectin domain is responsible for impaired matrix assembly and function in FOCD cartilage.

Objective

Previously, attempts have been made to isolate bone marrow derived mesenchymal stem cells (MSCs) from FOCD patients in order to study the organisation of extracellular matrix during chondrogenesis. The isolation was difficult and yields of MSCs were low. Therefore the objective of this study was to generate FOCD specific iPSC-derived MSCs to use as a study model for FOCD.

Methods

FOCD-iPSC lines were generated from skin fibroblasts of two FOCD patients by ectopic expression of Yamanaka Factors (Oct4, Sox2, Klf4, c-myc) that were encoded in retroviral vectors. To assess the pluripotency of induced hESC-like colonies, semiquantitative RT-PCR, immunocytochemistry, flow cytometry, teratoma formation in vivo and karyotype analysis were performed. Two non-patient iPSC lines were used as positive controls in all of the above experiments.

The disease phenotype was characterised in FOCD-iPSC lines by DNA sequence analysis in order to validate the disease related mutation. To generate the iPSC-derived FOCD model, FOCD-iPSCs were differentiated into MSC-like cells by isolating and expanding the outgrowth cells from the embryoid bodies (EBs). Positive and negative makers for MSCs were analysed by flow cytometry. Multipotency was assessed by chondrogenesis, adipogenesis and osteogenesis assays. Alizarin Red staining and Oil red O staining were used to detect calcium and fat in the differentiated cultures. Toluidine blue staining and dimethyl methylene blue (DMMB) assay were performed to detect acidic proteoglycan and to quantify GAG production in chondrogenic pellets.

Results

Seven hESC-like colonies were obtained from donor 1 and three hESC-like colonies were obtained from donor 2. Two colonies were randomly selected to represent each patient, named as FOCD1-2, FOCD1-30, FOCD2-9 and FOCD2-13. These colonies were expanded in culture, characterized then differentiated. The results of characterization of FOCD-iPSC lines indicated that retroviral reprogramming factors were silenced in all the cells and each FOCD-iPSC displayed a normal karyotype. Secondly, endogenous pluripotency markers (OCT4, SOX2, NANOG, SSEA4 and TRA1-81) were positively expressed in iPSCs. iPSCs were injected into SICD mice, after 6 weeks all of cells were able to form teratomas containing tissues from the three germ layers. In addition, the disease relative mutation was found to remain in all four patients' iPSCs.

For the generation of iPSC-derived FOCD model, iPSCs were differentiated into MSC like cells. The analysis of flow cytometry showed that the majority of the FOCD-MSC preparations were CD73, CD90 and CD105 positive and CD19, CD34 and HLADR negative. In addition, differentiation assays indicated that all FOCD-iPSC-derived MSC like cells were capable of differentiating into chondrocytes, osteoblasts and adipocytes.

Conclusion

We have successfully generated iPSC-derived FOCD model. Further studies will focus on investigating the molecular role of the mutation of aggrecan C-type lectin domain in the etiology of FOCD.

W-2177

THE EFFECT OF DONOR AGE ON THE INDUCTION OF PLURIPOTENCY IN BONE MARROW DERIVED MESENCHYMAL STEM CELLS FROM YOUNG AND AGED INDIVIDUALS

Matthias Megges[1], Sven Geissler[2], Patrik Stumpf[3], Richard Oreffo[3], James Adjaye[4]

[1]Molecular Embryology and Aging Group, Max Planck Institute for Molecular Genetics, Berlin, Germany, [2]Julius Wolff Institut, Campus Virchow-Klinikum, Berlin, Germany, [3]Faculty of Medicine, University of Southampton, Southampton General Hospital, Southhampton, United Kingdom, [4]Institute for Stem Cell Research and Regenerative Medicine, Heinrich Heine University Duesseldorf, Duesseldorf, Germany

Human bone marrow derived mesenchymal stem cells (hBM-MSCs) are a multipotent cell type capable of differentiating into osteoblasts, chondrocytes and adipocytes. However, the in vitro expansion and application of primary human mesenchymal stem cells are limited by their short life span in culture and restricted differentiation potential. These two features have been shown to be altered in somatic cells by reprogramming them to induced pluripotent stem cells (iPSCs), thus making iPSC derivation a promising approach to broaden the potential use of hBM-MSCs. Because iPSCs have great potential in regenerative therapies for age-related diseases, it is crucial to investigate reprogramming mechanisms within the context of hBM-MSCs from aged individuals in order to identify age-associated obstacles. Differences in metabolism, elevated levels of reactive oxygen species (ROS), proliferation, genome instability and senescence have been shown to be associated with increased donor age in hBM-MSCs. Age-relate features and their role in reprogramming have been analysed in a limited number of studies in human fibroblasts. However, little is known about the role of age-associated molecular changes during reprogramming of hBM-MSCs and the effect on the derived iPSCs. To obtain new insights into the potential roles of age related features in reprogramming of hMSCs to iPSCs we induced pluripotency in hBM-MSCs from fetal femur (55 days post conception) and hBM-MSCs of aged donors (60-70 years of age) via the classical retroviral and the non-integrating episomal plasmid based reprogramming approach. Higher levels of ROS, phosphorylated γH2AX and slower proliferation could be detected in hBM-MSCs from aged individuals. Karyotype abnormalities were not detected in BM-MSCs of both groups. Microarray-based comparative transcriptome analyses identified genes involved in p53 and hypoxia pathways, cell cycle regulation, steroid biosynthesis and glutathione metabolism as down-regulated in hBM-MSCs from aged donors in comparison to fetal femur hBM-MSCs. However, genes involved in focal adhesion, the lysosome and glycolysis pathways were up-regulated in hBM-MSCs from aged donors. Whether the identified age related features in hBM-MSCs are altered during the reprogramming process and if they persist in the respective iPS cells derived from them is under investigation. Human BM-MSCs from fetal femur could be reprogrammed more efficiently and faster compared to BM-MSCs from aged donors using both the retroviral and episomal plasmid-based reprogramming methods. We have derived a fully reprogrammed iPSC line from BM-MSCs from an aged donor (60 years of age) using retroviruses. Three fully reprogrammed iPSC lines have also been derived from fetal femur BM-MSCs using the episomal plasmid-based approach. However, episomal-based reprogramming of BM-MSCs from aged donors did not give rise to fully reprogrammed iPSCs. One aged hBM-MSC line gave rise to partially reprogrammed iPSC clones. In conclusion we have demonstrated that the efficiency of inducing pluripotency in hBM-MSCs is potentially affected by the age of the donor and that age-associated features such as elevated ROS levels, altered transcriptomes and cell cycle regulation diminish the pace and efficiency of inducing pluripotency in BM-MSCs from aged donors. We anticipate that our current findings might help identify and overcome age-associated roadblocks inherent to the derivation of iPSCs from hBM-MSCs.

IMPROVED REPROGRAMMING EFFICIENCY OF DISEASE SPECIFIC iPSC USING IMMORTALIZED HUMAN FORESKIN FIBROBLAST FEEDER CELLS

Pooja Teotia[1], Sujata Mohanty[1], Madhulika Kabra[2], Shefali Gulati[2], Balram Airan[1]
[A]Stem Cell Facility, [B]Pediatrics, [1]AIIMS, New Delhi, New Delhi, India

Generation of disease specific Induced Pluripotent Stem Cells (iPSC) represents a clear breakthrough in regenerative medicine. Hence, it is of great interest to establish optimal feeder and culture conditions that allow successful derivation & propagation of iPSC in clinically compatible conditions. Feki et. al. have established the Immortalized Human Foreskin Fibroblasts (I-HFF) feeder with an added advantages of endogenous bFGF secretion which at the same time supports the successful propagation of human Embryonic Stem Cells (ESC) and iPSC. In this study we aim to compare the derivation and propagation of iPSC using mouse feeder along with I-HFF feeder. Human skin fibroblast cells obtained from Duchenne Muscular Dystrophy patients, were used to derive iPSC cells using polycistronic lentiviral vector.
Study was initiated after the approval from Institute Ethics Committee (IEC) & Stem Cell Ethics Committee. In vitro-culture and expansion of fibroblasts cells were established using explant method. 1x 105 Fib cells were infected with hSTEMCCA (Human Stem Cell Cassette) lentiviral vector in the presence of 5ug/ml Polybrene. Next day, cells

were plated onto mouse and I-HFF feeder at a density of 1x104 cells onto the 6- well plate. After 24 hours, the medium was switched to reprogramming medium (ESC media and I-HFF conditioned media in 1:1 ratio).
Induced colonies were picked up based on human ES cell colony morphology and live staining for TRA-1-60 marker at days 16-24 post infection. The iPSC lines were assessed on the basis of morphology, expression of pluripotent makers by Immunoflorescence & RT-PCR. The in -vitro pluripotency and ability to differentiate into three germ layers was assessed by embryoid body formation. The experiments were performed using fibroblast cells from two different patients in triplicates.
We found that the average days of appearance of colonies was 16 on human feeder in comparison to 24 on mouse feeder. The total number of colonies obtained from two independent experiments at the end of reprogramming period was 41 and 23 on human and mouse feeders respectively. The average reprogramming efficiency of iPSC on human vs mouse feeders were 0.1 % and 0.05 % respectively as demonstrated by TRA 1-60 Live staining. Disease specific DMD-iPSC generated in this manner displayed ES cell like morphology, expressed stem cell markers TRA 1-60 and TRA 1-81. These iPSC ines exhibited endogenous expression of pluripotency markers like OCT-4, Sox2, Klf-4, cMYC and Nanog. The iPSC lines derived using both the feeder cells were able to spontaneously differentiate into cells of all three germ layers as characterized by Immnunofluorescence and RT-PCR assay.
Cumulatively, our study demonstrates that the (i) I-HFF human feeder was more efficient for the derivation of iPSC as evident by maximum number of fully reprogrammed clones as comparison to Mouse feeders, (ii) the emergence of iPSC clones took less reprogramming time on human feeders versus mouse feeders.The above observations can be attributed to the characteristic endogenous bFGF secretion by I-HFF feeders.
I-HFF cells at present are the best and economical candidate feeder cells for maintaining hESC/iPSC in culture as they minimize batch to batch variation and limiting the addition of exogenous bFGF.
Acknowledgment: We thank Prof. Anis Feki for providing us I-HFF cell lines.

MESENCHYMAL STEM CELL-LIKE CELLS DERIVED FROM INDUCED PLURIPOTENT STEM CELLS ENHANCE PERIODONTAL REGENERATION

Kim Hynes[1], Danijela Menicanin[1], Jennie Han[1], Victor Marino[1], Krysztof Morzik[1], Stan Gronthos[2], Mark Peter Bartold[1]

[1]Colgate Dental Research Centre, The University of Adelaide, Adelaide, Australia, [2]School of Medical Sciences, Mesenchymal Stem Cell Laboratory, University of Adelaide, Australia

Mesenchymal stem cells (MSC) have received significant attention in recent years due to their suitability for use in regenerative medicine. The therapeutic potential of MSC has however highlighted the need for identifying easily accessible and reliable sources of these cells. Current procedures for obtaining MSC are invasive, expensive and laborious. An attractive alternative source for obtaining large populations of MSC is through controlled differentiation of readily expandable induced pluripotent stem cells (iPSC).
We have established a protocol for inducing human iPSC to differentiate into MSC. MSC like cells were generated by differentiating iPSC in MSC media for two weeks followed by serial passaging to select for fast growing MSC like cells which have the capacity to attach and proliferate in mono-layer cultures, whilst eliminating slow-growing differentiating iPSC. Using this protocol MSC like cells were generated from iPSC lines derived from three different somatic tissues; gingiva, periodontal ligament, and foreskin. The resulting MSC like cells generated express key MSC-associated markers including (CD73, CD90, CD105, CD146 and CD166) and lacked expression of pluripotent markers (TRA160, TRA181 and alkaline phosphatise) and hematopoietic markers (CD14, CD34 and CD45). In vitro the iPSC-MSC like cells displayed a differential capacity to differentiate into osteoblasts, adipocytes and chondrocytes. In vivo subcutaneous implant of the iPSC-MSC like cells into NOD/SCID mice re-confirmed the differential differentiation capacity between the three iPSC-MSC like cells lines which was evident in the in vitro differentiation. When these iPSC-MSC like cells were implanted into periodontal defects in immunocompromised rats a significant increase in the amount of regeneration and newly formed mineralised tissue compared to control rats was noted.

Together these findings demonstrate that MSC like cells can be generated from iPS cells and could provide a novel and unlimited source of MSC cells which will be much safer for use in periodontal regenerative therapy.

SPECIAL AT-RICH BINDING PROTEIN SATB1 CONTROLS RE-ORGANIZATION OF LINEAGE-SPECIFIC DIFFERENTIATION PROGRAMS DURING KERATINOCYTE REPROGRAMMING TOWARDS THE INDUCED PLURIPOTENT STATE

Tatyana Y. Sharova[1], Mohammed I. Ahmed[3], Hye-Jung Han[4], Krzysztof Poterlowicz[3], Gustavo Mostoslavsky[2], Terumi Khowi-Shigematsu[4], Vladimir A. Botchkarev[3], **Andrey A. Sharov**[1]

[A]Dermatology, [B]Department of Medicine, [1]Boston University School of Medicine, Boston, MA, United States, [2]Centre for Skin Sciences, University of Bradford, Bradford, United Kingdom, [3]Lawrence Berkeley National Laboratory, Berkeley, CA, United States

Reprogramming of adult somatic cells towards the induced pluripotent state (iPS) is associated with marked changes in the genome organization and gene expression programs. Genome organiser and special AT-rich binding protein Satb1 plays an important role in the control of higher-order chromatin remodelling in a number of lineage-specific gene loci including keratinocyte-specific genes, which is required for maintenance of their transcriptionally active status. Here, we show that during reprogramming of primary epidermal keratinocytes isolated from transgenic mice expressing the Dox-inducible cassette of four mouse pluripotency genes (*Oct4, Sox2, Klf4* and *c-myc*) under *Col1a1* promoter, the expressions of Satb1 and keratinocyte-specific genes that constitute keratin type I and type II loci, as well as Epidermal Differentiation Complex locus, are markedly downregulated, while expression of the pluripotency gene Nanog is upregulated. ChIP analyses revealed Oct4 binding to regulatory regions of the *Satb1* gene indicating that pluripotency factors might directly repress Satb1 expression during reprogramming. Furthermore, treatment of keratinocytes with lentiviruses expressing Satb1 shRNA significantly accelerated appearance of Nanog+ cells and iPS colonies compared to the controls. Acceleration of iPS colony formation under shRNA-mediated Satb1 knockdown was accompanied by more rapid decrease in the expression of keratinocyte-specific genes, compared to controls. Thus, these data demonstrate that Oct4-mediated downregulation of Satb1 serves as an essential step in switching-off keratinocyte-specific gene expression programs during their reprogramming towards the induced pluripotent state

SOMATIC MOSAICISM IN HUMAN SKIN FIBROBLASTS REVEALED BY WHOLE GENOME SEQUENCING OF INDUCED PLURIPOTENT STEM CELLS

Alexej Abyzov[1], Alexander Eckehart Urban[2], Mark Gerstein[1], Flora M. Vaccarino[1]

[1]Program in Neurodevelopment and Regeneration, Yale University, New Haven, CT, United States, [2]Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, United States

Reprogramming human somatic cells into induced pluripotent stem cells (iPSC) has been suspected of causing genomic instability and leading to generation of de novo genomic variants. To explore this issue, we performed a whole-genome and transcriptome analysis of 20 human iPSC lines derived from primary skin fibroblasts of 7 individuals using next-generation sequencing. We find that, on average, an iPSC line manifests two copy number variants (CNVs) not apparent in the fibroblasts from which the iPSC was derived. Using qPCR, PCR, and digital droplet PCR (ddPCR) to amplify across the CNVs' breakpoints, we show that at least 50% of those CNVs are present as low frequency somatic genomic variants in parental fibroblasts and are manifested in iPSC colonies due to their clonal origin. We observed similar effect for single nucleotide variants (SNVs). Hence, reprogramming per se does not induce a large amount of genomic variation, while the amount of somatic mosaicism in the tissue used to produce iPSCs could be a challenge and, at least, needs to be taken into account. We also carried out correlative analyses between the detected manifested CNVs and gene expression determined by RNA-Seq from the same iPSC lines.

When analyzing expression levels (by RPKM) of genes intersecting manifested CNVs in iPSCs we found a clear tendency (p-value of 0.01 by Fischer's exact test) of increase in expression for genes in duplications and decrease in expression for genes in deletions. However there were also genes in deletion CNVs with increased expression and genes in duplication CNVs with decreased expression, an observation that invites further analysis to probe the epigenetic regulation of the affected loci.

AN IPS-DERIVED PLATFORM FOR THE STUDY OF MYOCARDIAL INFARCTION-ASSOCIATED DNA VARIANTS

Caroline Becker[1], Lauren Comisar[2], Eilene Duberow[1], Laurence Daheron[1], Vasan Ramachandran[3], Christopher J. O'Donnell[3], Kiran Musunuru[2], Chad A. Cowan[2]

[A]Harvard Stem Cell Institute, [B]Department of Stem Cell and Regenerative Biology, [1]Harvard University, Cambridge, MA, United States, [2]NHLBI Framingham Heart Study, Framingham, MA, United States

The discovery of new and effective treatments for human cardiovascular diseases requires the identification and validation of novel disease mechanisms. Recently, studies of genomic variation entered a new phase in which unbiased genome-wide association studies (GWAS) can identify novel genetic loci associated with common diseases. We have recently described 95 loci associated with blood lipid levels -- LDL cholesterol (LDL-C), HDL cholesterol (HDL-C), or triglycerides -- which are strongly associated with risk for myocardial infarction (MI) in the NHLBI Framingham Heart Study (FHS) and other population cohorts. Much work will be needed to translate the novel associations into functional insights and, ultimately, therapies to reduce the risk of MI.

A key step is to determine how these genetic loci affect phenotypes in human tissue types relevant to lipid metabolism, principally liver and adipose. We have performed expression quantitative trait locus (eQTL) analyses of genotype vs. gene expression in surgical liver and adipose tissue samples from patients; from this work, we found a strong association between an LDL-C- and MI-associated SNP on chromosome 1p13 -- rs12740374 -- and hepatic expression of the *SORT1* gene. However, these studies were limited by scarcity of actual human tissue and the inability to address key cellular phenotypes such as lipoprotein secretion. Thus, there is a need to establish infinitely renewable sources of hepatocytes and adipocytes from patients of defined genotypes.

Here we describe our proposal to generate iPS cell lines from ~200 individuals in the Framingham Offspring Cohort with defined genotypes at chromosome 1p13 rs12740374. We have collected blood samples from over 2260 donors for reprogramming, and have generated 60 iPS lines from 13 donors. With respect to the MI-associated SNP, six donors were of the homozygous major genotype (that is associated with increased LDL-C and risk of MI), four were of the homozygous minor genotype, and three were of the heterozygous genotype. We plan to differentiate these iPS cells into functional hepatocytes and adipocytes and perform gene expression, metabolomic profiling and functional assays. Our goal is to identify new disease mechanisms and ultimately develop new, improved therapies to reduce the risk of MI.

Juvenile Myelomonocytic Leukemia (JMML) is an aggressive childhood myeloproliferative disorder caused by NF1, NRAS, KRAS, PTPN11, or CBL mutations that induce Ras pathway activation with associated hypersensitivity to cytokine stimulation in myeloid progenitor cells. Understanding the pathophysiology of JMML and developing new treatments is constrained by limited access to relevant patient material. To address this problem, we generated induced pluripotent stem cell (iPSC) lines from malignant cells of two JMML patients with somatic heterozygous E76K missense mutations in PTPN11, which encodes the non-receptor tyrosine phosphatase SHP-2. In vitro differentiation of JMML iPSCs produced myeloid cells with increased proliferative capacity, hypersensitivity to granulocyte-macrophage colony-stimulating factor (GM-CSF), and sustained STAT5 and ERK phosphorylation, similar to what is observed in primary JMML cells from patients. Pharmacological inhibition of MEK kinase in iPSC-derived JMML cells inhibited basal activation of pERK, as well as abrogated GM-CSF-induced pERK, providing rationale for a potential targeted therapy. Our studies offer renewable sources of biologically relevant human cells in which to explore the pathophysiology and treatment of JMML. More generally, we illustrate the utility of iPSCs for in vitro modeling of a human malignancy.

ERYTHROCYTE INDUCTION FROM HUMAN INDUCED PLURIPOTENT STEM CELLS INDEPENDENT OF SOMATIC CELL ORIGIN

Isabel Dorn[1], Peter Schlenke[2], Martina Radstaak[3], Katharina Klich[1], Marcos J. Arauzo-Bravo[1], Simon Santourlidis[4], Boris Burr[1], Jeong Beom Kim[5], Martin Einhaus[6], Hans R. Schoeler[1], Holm Zaehres[1]
[1]Max Planck Institute for Molecular Biomedicine, Muenster, Germany, [2]Institute for Transfusion Medicine and Transplantation Immunology, University of Muenster, Muenster, Germany, [3]Max Planck institute for Molecular Biomedicine, Muenster, Germany, [4]ITZ, Heinrich-Heine-University, Düsseldorf, Germany, [5]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of, [6]LADR, Geesthacht, Germany

Epigenetic memory in induced pluripotent stem (iPS) cells in
regard to their donor cell type of origin could lead to variations in their
differentiation capacities. We have generated iPS cells from human neural stem cells (NSC-iPS) and human cord blood derived CD34+ hematopoietic stem cells (HSC) (CD34-iPS) as well as fibroblasts (Fib-iPS) and evaluated their differentiation potential into hematopoietic precursor and mature red blood cells (RBC). Erythrocytes represent a defined end point of blood differentiation, while self-renewing, repopulating HSC, have not been successfully differentiated from human pluripotent stem cells until now. For hematopoietic induction, iPS cells were allowed to form embryoid bodies (EBs) under cytokine stimulation for 21 days. Thereafter, EBs were dissociated and single cells were applied to a three-step protocol for human erythropoiesis for additional 18-21 days. Hematopoietic differentiation was analysed by flow cytometry (CD43, CD34, CD45, CD36, glycophorin A) and colony formation in semisolid media. We have found a similar hematopoietic induction potential among our cell lines. After EB dissociation on day 21, hematopoietic commitment, measured by CD43 expression, was 31.9%±20.1% for CD34-iPS, 18.6%±10.3% for NSC-iPS and 17%±13% for Fib-iPS. Colony-forming unit assays demonstrate a similar distribution of myeloid (CFU-M/CFU-GM), erythroid (BFU-E/CFU-E) and more immature mixed (CFU-GEMM) colonies among iPS cell lines (CD34-iPS: 66±37 myeloid, 11±6 erythroid, 3±3 CFU-GEMM; NSC-iPS 77±52 myeloid, 3±2 erythroid, 1±1 CFU-GEMM; Fib-iPS: 58±28 myeloid, 6±7 erythroid, 1±1 CFU-GEMM). Hematopoietic cells further developed into erythroid precursors as determined by >90% expression of glycophorin A, followed by maturation into normoblasts and partially enucleated RBC (enucleation rate CD34-iPS 27.3%±4.9%, NSC-iPS 28.4%±10.9%, Fib-iPS 20.7%±5%). All human iPS derived mature erythrocytes predominantly present fetal hemoglobin (85%-90%), some embryonic (6%-7%) and only a minor amount of adult hemoglobin (2%-3%) as demonstrated by high performance liquid chromatographie. We have performed genome-wide DNA methylation profiling, giving some evidence of epigenetic marks during reprogramming. Our data indicate and support other data that epigenetic differences in human iPS cell lines generated of different donor cell type of origin (ectodermal neural versus mesodermal blood cells or fibroblasts) do not have a significant impact on their differentiation potential towards blood lineages.

PURIFYING AND EXPENDING HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS FOR DERIVING INDUCED PLURIPOTENT STEM CELLS

Mu-Hua Chung[1], Chia-Nan Liao[2], Yi-Shiu Chen[1], Lung-Bin Lu[1], Akon Higuchi[3], Qing-Dong Ling[1]
[1]Cathay Medical Research Institute, Cathay General Hospital, New Taipei City, Taiwan, [A]Graduate Institute of Systems Biology and Bioinformatics, [B]Department of Chemical & Materials Engineering, [2]National Central University, Chungli, Taiwan

Induced pluripotent stem cells (iPSCs) have become a significant source for regenerative medicine and tissue engineering. Recent studies demonstrated that the techniques of iPSCs are able to be applied in clinical area such as personal medicine, tissue engineering and drug discovery. However, the somatic source from human for deriving human iPSCs is becoming an important issue. Thus developing an uncomplicated and efficient method to collect source cells is imperative in clinical application. In this study, we established a model to purify and expend mononuclear cells from human peripheral blood (PBMCs) with a simple and efficient procedure for inducing pluripotent stem cells. We isolated PBMCs from 3ml of whole blood collected from patients through by Ficoll gradient method and expanded cells with ALyS505N medium plus interleukin 2 (IL2) in tube for primary culture. Our results showed that a significant increase in cell numbers were up to above 600% in primary and second passages expending, as well as the types of cells were confirmed by flow cytometry. The human iPSCs were derived from cells in second passages by retroviral transduction of defined four transcription factors: Oct4, Sox2, Klf4 and c-Myc. However, expanded PBMCs were able to be continually culture to third passages in furthermore and the cells growth rate has decreased with the times of passage. These results indicate that our developed methods for isolating and expanding PBMCs could provide an efficacious process and desirable cells source for deriving the human iPSCs in clinical application in the future.

W-2188

GENE EXPRESSION SIGNATURE OF PORCINE IPS CELLS FROM DIFFERENT LABS SHOWS THE PROFILES DISSIMILAR TO MOUSE AND HUMAN

Yajun Liu, Huayan Wang
Dept. Biotechnology, Northwest A&F University, Yangling, Shaanxi, China

Some issues such as the incomplete reprogramming of porcine iPS cells(piPSCs), lacking the detailed database for porcine gene regulatory network and the difficulty to create the chimera animal of piPSCs precluded the application of this technology. To solve above problems and better understand the mechanism of porcine cell reprogramming, we analyzed the transcriptional profiles of porcine iPS cell lines using Affymetrix GeneChip Porcine Genome Array. Porcine iPS cell lines were
derived from our lab (30AC5 and PS24, which met all criteria required for a claim of pluripotency), Dr. Xiao's lab (iPF4-2, which was used to generate the cloned piglets), Dr. West's lab (piPS-w, which was used to create chimera pig) and Dr. Roberts' lab (IC1, ID4, ID6 and pESK, which data were extracted from GEO, GSE15472). Our results demonstrated that cell surface proteins of EpCAM (epithelial cells adhesion molecule) and Rex1 were significantly upregulated in complete reprogrammed porcine iPSCs, but not in partially reprogrammed cells, suggesting that these genes could be markers for evaluating porcine cell reprogramming. The number of upregulated genes in pig iPS cells was 1846 out of 23,937 gene probes. Ingenuity Pathways Analysis (IPA) revealed several pathways that might play important roles during the porcine cell reprogramming, such as Sertoli-Sertoli Cell Junction signal pathway, Ga12/13 signal pathway, and BMP signal pathway etc. We analyzed gene expression level of the six key developmental signaling pathways, including JAK-STAT, NOTCH, TGFb, WNT, MAPK and VEGF. These results demonstrate that the core transcriptional network to maintain pluripotency and self-renewal in pig may be different from mouse and human. Pig iPSCs are lack specification naïve state markers, such as Kruppel-like factors (Klf2/4) and Tbx3, whereas, the markers for primed state (e.g. Otx2 and Fabp7) were upregulated significantly. The similarities among

piPSCs, hiPSCs and mEpiSCs underscored the possibility that traditional culture conditions cannot used to maintain long-term proliferation of pig pluripotent cells with inherent instability of naïve pluripotency. We also identified that aberrant silencing of Dlk1-Dio3 domain was instantaneous response for factor-induced reprogramming in different species. Aberrant silencing of Dlk1-Dio3 domain is a common outcome upon induced reprogramming in pig, mouse and human. Real time PCR results confirm the notion that silencing of this cluster is a common outcome upon factor-mediated reprogramming in pig. The defect in piPS partially explains the rare success of the birth of chimeric and cloned offspring. In conclusion, our results provide a fundamental resource for better understanding of the complex genetic network that maintains pluripotency in pig.

W-2191

SCREENING OF NEW FACTORS THAT INFLUENCE THE PROCESS OF SOMATIC REPROGRAMMING MEDIATED VIA FORCED EXPRESSION OF SPECIFIC GENE

Tatsuya Yamakawa[1], Yoshiko Sato[1], Yuki Takase[1], Naoki Goshima[2], Keisuke Okita[1], Shinya Yamanaka[1]

[1]Department of Reprogramming Science, Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan, [2]Biomedicinal Information Research Centre, National Institute of Advanced Industrial Science and Technology, Tokyo, Japan

Induced pluripotent stem (iPS) cells were initially generated from mouse and human fibroblast by retrovirus- or lentivirus- mediated infection of following four factors, Oct3/4, Sox2 with either Klf4 and c-Myc or Nanog and Lin28. Human iPS cell could be applicable to clinical application such as disease modeling, drug discovery and toxicology. However, it is still unclear what happens during the somatic reprogramming via forced expression of several genes. Until now, many researchers have found out the new reprogramming genes that can improve reprogramming efficiency or replace the first-reported 4 genes. Some of these genes have been reveled to have direct impact on reprogramming process without affecting cell proliferation. The analysis of such genes may be useful to clear mechanisms of cellular reprogramming, which is important not only for stem cell biology but also for clinical application of iPS cell.

To find new genes that influence on the reprogramming process, we established a screening system. As candidates, we employed human cDNA library consisted of 2500 transcription factors and 300 kinases. Each candidate genes were transfected into human dermal fibroblast with basic 5 factors (OCT3/4, SOX2, KLf4, L-MYC and LIN28) via plasmid method and evaluated whether they influenced on iPS generation efficiency as the result of their impact on reprogramming process. We used mock as a negative control and GLIS1 as a positive control. Induction efficiency of each sample was calculated by comparison between the number of human ES-like colonies induced by the each factor and mock.

This kind of screening has usually been performed by using mouse embryonic fibroblast and virus-mediated transfection method, because of their simple and easy procedure to handle many samples. In contrast, we employed human fibroblast as the cell source and plasmid-mediated transfection for transgene expression. The reason why we chose these methods is that the reprogramming factors don't always work in the same way as they were originally reported when used in different methods or species. Our screening system will enable to find new factors which could provide some insights of reprogramming process from human cells, especially in the methods enable to medical application. Still the screening is going on, we show the development of our screening assay using automatic colony-count system with BioStationCT and summary of the results. We detected several factors which positively or negatively affected on the induction efficiency. These library-derived new factors can also influence iPS induction from fibroblasts of two different donors. Interestingly, some of these positive factors have the same protein motif, suggesting they have some important function during somatic reprogramming. Additionally, we checked the mRNA expression changes of both positive and negative factors during iPS generation. By analyzing factors which affect on iPS induction efficiency, we are trying to uncover underlying mechanisms of somatic reprogramming. The new factors we found would be also useful to develop appropriate reprogramming methods for clinical application.

BENEFICIAL EFFECTS OF METABOLIC CONTROL IN THE ACQUISITION AND MAINTENANCE OF PLURIPOTENCY

Myung Jin Son[1], Mi-Young Son[1], Binna Seol[1], Min-Jeong Kim[1], Chae Hwa Yoo[1], Hee–Jun Na[1], Myung-Kwan Han[2], Yee Sook Cho[1]

[1]Regenerative Medicine Research Center, Korea Research Institute of Bioscience and Biotechnology (KRIBB), Daejeon, Korea, Republic of, [2]Department of Microbiology, Institute for Medical Sciences, Chonbuk National University Medical School, Jeonju, Korea, Republic of

Cross-talk between intracellular signaling pathways has been extensively studied to understand the pluripotency of human pluripotent stem cells (hPSCs), including human embryonic stem cells (hESCs) and human induced pluripotent stem cells (hiPSCs); however, the contribution of NAD^+-dependent pathways remains largely unknown. Here, we show that NAD^+ depletion by FK866 (a potent inhibitor of NAD^+ biosynthesis) was fatal in hPSCs, particularly when deriving pluripotent cells from somatic cells and maintaining pluripotency. NAD and its precursors (nicotinamide (NAM) and nicotinic acid (NA)) fully replenished the NAD^+ depletion by FK866 in hPSCs. However, only NAM effectively enhanced the reprogramming efficiency and kinetics of hiPSC generation and was also significantly advantageous for the maintenance of undifferentiated hPSCs. Our molecular and functional studies reveal that NAM lowers the barriers to reprogramming by accelerating cell proliferation and protecting cells from apoptosis and senescence. Our findings establish that adequate intracellular NAD^+ content is crucial for pluripotency; the distinct effects of NAM on pluripotency may be dependent not only on its metabolic advantage as a NAD^+ precursor but also on the ability of NAM to enhance resistance to cellular stress.

W-2192

A NOVEL UTF1-TOMATO PLURIPOTENCY REPORTER MOUSE

Peter Droge[1], Amir Morschedi[1], Wei-Ping Yu[2]

[1]Nanyang Technological Uiversity, Singapore, Singapore, [2]Biomedical Sciences Institute, Singapore, Singapore

The Utf1 protein (undifferentiated embryonic cell transcription factor 1) was first described in 1998 by Okuda *et al.* in an Article published in the *EMBO J.* Today, Utf1 is established as a member of the core transcription network which defines and regulates the pluripotent embryonic stem cell state. Our previous studies have shown that the human *Utf1* control elements (i.e. the promoter and the 3`-enhancer) can be employed as very reliable pluripotency reporter in human and mouse ES/iPSCs. In agreement with this, a more recent study by R. Jaenisch and coworkers published in *Cell* identified *Utf1* transcription, which is a direct downstream target gene of Oct4 and Sox2 (and presumably Nanog), as one of the most reliable predictors for the execution of the complete reprogramming program during iPSC formation. Furthermore, it was shown in a separate recent *Cell* study that the Utf1 protein ensures rapid proliferation and coordinated differentiation of ESCs through chromatin modification and the control of mRNA decapping. Hence, it appears timely to briefly present here our preliminary assessment of a novel *Utf1-tomato* knock-in pluripotency reporter mouse. With further characterization, this animal system has the potential of becoming a very useful tool for a number of *ex vivo* and *in vivo* studies, possibly also permitting questions beyond the topic of iPSC formation.

GENERATION OF INDUCED PLURIPOTENT STEM CELLS USING RAT MESENCHYMAL STROMAL CELLS ORIGINATED FROM A NEW MODEL OF METABOLIC SYNDROME

Nana Ninagawa Takenaka[1], Mami Kobayashi[1], Yuka Kawabata[1], Nagata Kohzo[2], Shigeko Torihashi[1]

[A]Department of Rehabilitation Sciences, [B]Department of Pathophysiological Laboratory Sciences, [1]Nagoya University Graduate School of Medicine, Nagoya, Japan

We recently established a new animal model of metabolic syndrome (MetS), the DahlS.Z-*Lepr*^{fa}/*Lepr*^{fa} (DS/obese) rat, by crossing Dahl salt-sensitive (DS) rats with Zucker rats harboring a missense mutation in the leptin receptor gene (*Lepr*^{fa}). Body weight and visceral. subcutaneous fat masses were significantly increased, and blood pressure was higher in DS/obese rats when compared with homozygous lean littermates (DS/lean) rats (Hattori et al. 2011). Although the phenotype of DS/obese rats is similar to that of MetS in humans, the pathophysiological and metabolic characteristics in each cell type remain to be clarified. Hence, induced pluripotent stem cells (iPSCs) derived from MetS rats serve to promote investigations *in vitro*.
Here, we report the establishment of the rat iPS cells (riPSCs) from DS/obese and DS/lean rats to investigate cell biology of MetS *in vitro*. We generated riPSCs from mesenchymal stromal cells (MSCs) collected from adult rat subcutaneous adipose tissues of DS/obese and DS/lean rats individually. MSCs from both rats were introduced three mouse reprogramming factors (*OCT3/4, SOX2, and KLF4*) by lentiviral vectors according to the previous report with some modifications (Kobayashi et al. 2009). They were then cultured with SNL feeder cells in the presence of exogenous leukemia inhibitory factor (LIF) to establish iPS cells as o-riPSCs and l-riPSCs, respectively. The lentiviral transduction yield ES cell-like colonies from individual rat MSCs, and these colonies with EGFP were alkaline phosphatase-positive, indicating pluripotent stem cells. Then, we tried to pick up ES cell-like colonies, trypsinized them into single cells, and transferred them to 24-well plates for further expansion. Established riPSCs could expand without any morphological changes. Like mouse ES cells, both o-riPSCs and l-riPSCs expressed stage-specific embryonic antigen (SSEA)-1, and Nanog protein. We also confirmed that both riPSCs expressed many undifferentiated ESC-marker genes, including *Nanog, OCT3/4, Klf4, Rex1, Tdgf2, Sox2, Eras,* and *fibroblast growth factor 4 (Fgf4)* by RT-PCR. We examined the capacity of riPSCs for *in vivo* differentiation, and assessed teratoma formation with microscopy of hematoxylin/eosin (HE) stained sections. The results suggest that our riPSCs had been reprogrammed into pluripotent state and possessed the capacity for differentiation into cells of three germ layers.
Thus, we succeeded in generating riPSCs from MSCs of DS/obese and DS/lean rats using only three reprogramming factors. These riPSCs will serve as highly effective tools for the investigation of MetS pathophysiology *in vitro*.

DERIVATION AND CHARACTERIZATION OF RAT IPS CELLS USING A MOUSE STEMCCA REPROGRAMMING VECTOR

Pavan Rajanahalli, Mark L. Weiss
Kansas State University, Manhattan, KS, United States

Rats are considered an important animal model system by having many similarities to humans in terms of physiological processes of the cardiovascular, metabolic and neurological systems. Induced pluripotent stem cell (iPSC) technology has great potential to advance in the field of regenerative medicine by generating patient-specific stem cell for treatment or in vitro disease modeling. Here, we derived rat iPSC's from Fischer 344 embryonic fibroblasts using a mouse STEMCCA cre-excisable reprogramming vector expressing Oct-4, Klf4, Sox-2 and c-Myc. Once rat ESC-like colonies were derived, we removed the transgene vector and demonstrated that one of the clones tested showed a normal karyotype by G-banding. The iPSC colonies demonstrate a morphology that is similar to rat embryonic stem cells (ESCs), are positively stained for pluripotency markers such as alkaline phosphatase, Oct-4, Nanog, Sox-2 and SSEA-1. The rat iPSCs have been maintained more than 27 passages. Using a custom-designed microarray, we compared the gene expression profile of rat iPSCs to rat ESCs and there was good similarity between the two with the exception of Cdx2 expression which is expressed in rat ESCs. We plan to further characterize the rat iPSCs to determine whether they can undergo neural differentiation in vitro and whether the micro RNA expression of rat iPSCs is similar to rat ESCs.

W-2196

QUANTITATIVE FLUORESCENT IN VITRO ASSAY FOR MONITORING DIFFERENTIATION OF PLURIPOTENT STEM CELLS TOWARDS MYELINATING OLIGODENDROCYTES

Antje Arnold, Agatha Lyczek, Jiangyang Zhang, Miroslaw Janowski, Jeff WM Bulte, Piotr Walczak

Dept. of Radiology, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

Evidence is mounting that transplantation of glial-restricted progenitor cells (GRPs) is a promising approach for restoration of brain function in patients suffering from de/dysmyelinating neurological disorders. Rodent studies demonstrated that transplantation of GRPs into the CNS results in the generation of new myelinating oligodendrocytes and robust therapeutic effect. It is imperative to develop techniques for non-invasive monitoring of graft functionality for clinical translation. To this end, we applied diffusion tensor MRI (DTI) for *in vivo* imaging of myelination in *shi/shi rag2*$^{-/-}$ mice transplanted with GRPs. *In vivo* DTI showed improvement of imaging parameters with reduced radial diffusivity within white matter structures in transplanted compared to control mice. Immunohistochemistry revealed robust myelination by transplanted cells and migration from ventricles to the brain parenchyma, particularly into white matter. This was in good agreement with MRI findings. The life span of transplanted *shi/shi rag2*$^{-/-}$ mice was extended. Our results strongly support this strategy with transplantation of GRPs for de/dysmyelination.

One limitation of this strategy is the inadequate access to human fetal tissue for the derivation of human GRPs. To overcome this issue, we propose to derive GRPs from pluripotent cells as an unlimited cell source. Dr. Goldman's group showed that derivation of GRPs from iPSCs requires an extremely lengthy differentiation procedure (120 days) exemplifying another challenge. To address this, we have developed a robust *in vitro* differentiation assay using fluorescence as a readout for oligodendrocyte differentiation with the goal of accelerating the differentiation process.

Here, we generated iPSCs derived from proteolipid protein-green fluorescent protein (PLP-GFP) transgenic mice. PLP-GFP iPSCs did not express GFP as GFP expression is induced under the oligodendrocyte-specific PLP promoter. We are differentiating iPSCs towards GRPs and mature oligodendrocytes, with the GFP expression used as the primary quantitative readout for assessing efficiency of this differentiation process. To properly model and stimulate *in vitro* differentiation towards myelinating oligodendrocytes, we applied GRPs and neural stem cells (NSCs) to a co-culture system. NSCs were derived from transgenic mice expressing DsRed under β-actin promoter. With this combination of DsRed-NSC and inducible PLP-GFP iPS-derived GRPs we are able to monitor the differentiation of iPSCs towards mature oligodendrocytes with fluorescence. Preliminary data on oligodendrocyte differentiation of primary PLP-GFP+ GRPs demonstrated that GFP fluorescence intensity increased during the differentiation process. Oligodendrocytes were evaluated based on the morphology and immunostaining for oligodendrocyte-specific markers (Olig2, MBP). We are currently applying the same differentiation protocol for our PLP-GFP+ GRP-iPSCs with efficiency of differentiation assessed by longitudinal measurements of GFP expression, immunostaining and qPCR for oligo-, neuronal- and *astrocyte-specific* markers (Olig2, MBP, Tju1, GFAP). Further characterization will include transplantation into neonatal *shi/shi rag2*$^{-/-}$ mice with DTI. In conclusion, we present an *in vitro* approach for monitoring differentiation of iPS cells towards myelinating oligodendrocytes using fluorescence readout and thus facilitating optimization of differentiation protocol.

W-2197

A ROBUST SECONDARY SYSTEM FOR HIGH-THROUGHPUT STUDIES OF REPROGRAMMING AND PLURIPOTENCY PATHWAYS IN HUMAN CELLS

Davide Cacchiarelli[1], Magali Soumillon[1], Cole Trapnell[1], Xiaolan Zhang[2], Casey Gifford[1], Veronika Akopian[1], Alexander Meissner[1], John L. Rinn[1], David T. Scadden[1], Eric S. Lander[2], Tarjei S. Mikkelsen[1]

[1]Harvard Stem Cell Institute and Department of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States, [2]Broad Institute of Harvard and MIT, Cambridge, MA, United States

Reprogramming of somatic cells to induced pluripotent stem cells (iPSC) is an inefficient and long process. Reprogramming efficiency is highly dependent on the stoichiometry of the ectopically expressed reprogramming factors, which is difficult to obtain in a uniform manner with many delivery systems. Drug-inducible secondary systems, consisting of fibroblasts differentiated from iPSCs obtained through doxycycline-inducible reprogramming factors, represent genetically homogeneous systems that partially address this technical issue. Unfortunately, existing sec-

ondary systems suffer from several limitations, mainly related to the limited lifespan and expansion capability of the secondary somatic cells. Senescence affects the consistency of both derivation and reprogramming of secondary fibroblasts, making the system challenging to use for high-throughput screening and genome editing-based studies.
To generate an improved human secondary system, we first derived new iPSC lines using a doxycycline-inducible polycistronic Oct4-Klf4-Myc-Sox2 vector to minimize integration events and to maintain a controlled stoichiometry. Secondary fibroblast clones obtained from directed differentiation of these inducible iPSCs were then engineered to extend their life span. This process, coupled with optimization of defined growth conditions, facilitated the generation of a secondary cell line that is capable of a undergoing a large number of cell divisions without losing its high reprogramming potential or the genetic and epigenetic characteristics of primary cells.
iPSCs derived from the new secondary cells are directly comparable to those obtained from established primary reprogramming strategies, with the added advantage that the reprogramming is highly consistent and uniform. We have applied this unique feature to extensively characterize the molecular events occurring during reprogramming of human cells by isolating different intermediate populations and profiling them using high-throughput strategies, including RNA-seq and ChIP-seq. In addition, we are testing the robustness of many assays in this system for the study of reprogramming and pluripotency pathways, including high-throughput functional RNAi screening, massively parallel reporter assays (MPRA) and synthetic nuclease-mediated genome editing..
This newly developed secondary system represents a handy and powerful tool for testing functional hypotheses and has the potential to allow deep dissection of the molecular events underlying cellular reprogramming in human cells.

W-2201

RNA SPLICING REGULATION DURING SOMATIC CELL REPROGRAMMING

Sho Ohta[1], Eisuke Nishida[1], Shinya Yamanaka[2], Takuya Yamamoto[2]
[A]Graduate School of Biostudies, [B]CiRA, iCeMS, [1]Kyoto Univ, Kyoto, Japan

Despite the extensive studies on somatic cell reprogramming, the molecular mechanisms underlying the reprogramming process are still unclear. Here we report our analysis on changes in alternative splicing during reprogramming. By combining deep sequencing with high-throughput quantitative RT-PCR, we revealed drastic changes in genome-wide splicing profiles during the reprogramming process. Our analysis identified more than 600 genes, whose splicing patterns are changed during iPS cell induction from mouse embryonic fibroblasts (MEFs). Computational analysis of primary sequences demonstrated that several motifs are enriched in sequences within, and adjacent to, the differentially expressed skipped exons between MEFs and iPS cells. Moreover, we also found that the lengths of the introns around exons, which are preferentially included in iPS cells, tend to be shorter. In addition, we performed siRNA screen for the RNA binding proteins that are responsible for the splicing events in pluripotent stem cells. Consequently, we obtained a number of RNA-binding protein-encoding genes whose depletion causes alteration in splicing patterns in pluripotent stem cells, and some of which are necessary for somatic cell reprogramming. These findings indicate that post-transcriptional as well as transcriptional regulation mechanisms are integral parts of the molecular network in the reprogramming process and the pluripotency maintenance. Our results should contribute to elucidation of the mechanisms underlying somatic cell reprogramming.

W-2202

INVESTIGATION OF THE X CHROMOSOME VIA USE OF PLURIPOTENT STEM CELLS WITH HUMAN X ANEUPLOIDIES

Antonia A. Dominguez, Dian Yang, Shawn Chavez, Rosaria Chiang, Renee Reijo Pera
Stanford University, Stanford, CA, United States

Our goal is to examine the role of the human X chromosome in germ line and somatic development in an induced pluripotent stem cell (iPSC) system. For this purpose, we are developing and characterizing iPSC lines from women with different X chromosome dosages. Turner Syndrome (TS) females have partial or complete loss of the second

X chromosome, resulting in a 45,X karyotype. Three percent of pregnancies begin as 45,X; however, 99% of these are spontaneously terminated, and females who live have a wide variety of clinical characteristics including short stature and infertility. Triple X syndrome (XXX) is a trisomy of the X chromosome and results in tall stature, infertility and sporadic learning disorders. Here, we report derivation of iPSCs from four TS females and two control females. All iPSCs maintained original karyotypes, expressed key pluripotency markers and spontaneously differentiated in vivo and in vitro into the three germ layers. We expect that iPSCs derived from TS and XXX females may accurately replicate the haploinsufficiency and X chromosome aberrations observed in the original patient, making them an ideal model to investigate the role of the X chromosome in early development and germ cell development and test this concept further.

First, we determined that expression levels of X chromosome genes were similar between single blastomeres of day 2 and day 3 human embryos and iPSCs, which we used to model early development. We then investigated X chromosome gene expression differences amongst TS, control and XXX iPSC lines. We analyzed the expression of 96 genes including X-linked and pluripotency genes, at the single cell level and observed small but statistically insignificant differences in gene expression. We also compared the whole transcriptome across different iPSCs lines via RNA-seq and observed differential expression level of multiple X chromosome genes was discovered. We are currently examining differences in more detail.

Infertility in females with only one X chromosome has been previously established, however, no specific X-linked genes have been correlated with infertility because of the lack of phenotype in the TS mouse model (39,X). To address whether the absence or gain of the second X chromosome results in defects in the formation of primordial germ cells (PGCs) we are currently carrying out directed differentiation to the PGC lineage using BMPs, retinoic acid and the VASA:GFP reporter construct. Single cell expression analysis as well as RNA-sequencing is being conducted to analyze the expression of X-linked and germ cell genes as TS, control and XXX hiPSC lines as they are differentiated into the germ cell lineage.

Overall, despite the large variety of clinical characteristics seen in TS and XXX females, only one gene has been linked to specific phenotype in TS females. It is hoped that results of our studies will identify expression differences of X-linked genes that can be investigated further for their necessity in normal early development and proper germ cell development.

Reprogramming

W-2203

CHARACTERIZATION OF AID-DEFICIENT IPS CELLS

Ren Shimamoto[1], Naoki Amano[1], Tomoko Ichisaka[1], Akira Watanabe[1], Keisuke Okita[1], Shinya Yamanaka[2]

[1]Center for iPS Cell Research and Application (CiRA), Kyoto, Japan, [2]Center for iPS Cell Research and Application (CiRA), Yamanaka iPS Cell Special Project, Gladstone Institute of Cardiovascular Disease, Institute for Integrated Cell-Material Sciences (iCeMS), Kyoto, Japan

IPS cells can be generated by introducing defined factors into somatic cells. It has been shown that epigenetic status, such as DNA methylation and histone modification, changes dramatically during iPS cells generation. For instance, DNA methylation level of *Oct4* and *Nanog* promoters decrease during iPS cell generation. However, the underlying mechanism of demethylation is still unclear.

Activation-induced cytidine deaminase (Aid) converts methylated and unmethylated cytosine to thymine and uracil respectively by removing amine. Recently some papers suggested that Aid is involved in DNA demethylation during developmental processes in zebrafish and mouse. Interestingly, AID was also shown to be involved in DNA demethylation activity in cell-fusion-mediated reprogramming of mammalian cells. One recent report revealed that the transient knockdown of Aid hampered the initiation of mouse iPS cell generation. Taken together, we hypothesized that Aid would be involved in DNA demethylation during iPS cell generation.

In this study, we employed loss of function approach and examined the effect of Aid depletion on DNA methylation status in iPS cells. Aid knockout mice were crossed with Nanog-GFP mice which have GFP reporter under the control of a pluripotent stem cell marker, Nanog. Oct3/4, Sox2, Klf4 and c-Myc were introduced into Aid knockout mouse

embryonic fibroblasts by retrovirus. Contrary to our expectation, Nanog-GFP positive iPS colonies emerged from Aid KO MEFs. The induction efficiency was not different from that of wild-type iPS cells (Wt iPS cells). In addition, the overexpression of Aid did not affect the induction efficiency.
We examined morphology, proliferation, differentiation potential, RNA expression and DNA methylation of Aid KO iPS cells. Aid KO iPS cells showed normal proliferation and gave rise to three germ layers in teratoma forming assay. Moreover, Aid KO iPS cells could give rise to chimera by blastocyst injection. Microarray analysis showed that there were few differences between Aid KO iPS cells and Wt iPS cells. These results suggest that Aid KO iPS cells were similar to Wt iPS cells in terms of ability of self-renewal and pluripotency.
In the DNA methylation analysis, first *Nanog* and *Oct3/4* promoter regions were analyzed. However, in Aid KO iPS cells both regions were hypomethylated similar to that of Wt iPS cells. The global DNA methylation level examined by LINE1 and B1 repeat sequences did not show significant difference. Then, we searched for specifically methylated regions in Aid KO iPS cells by comprehensive DNA methylation assay. The genomic fragments were concentrated by immunoprecipitation using methylted CpG binding protein and were analyzed by deep sequencing. However, only few differences were found between Wt and Aid KO iPS cells. Consequently, the effect of Aid depletion on DNA demethylation was not observed in our analyses.

GLOBAL ALLELIC EXPRESSION PROFILING OF INDUCED PLURIPOTENT STEM CELLS AND THEIR DIFFERENTIATED NEURAL STEM CELL PROGENY

Aaron R. Jeffries[1], Dafe A. Uwanogho[1], Graham Cocks[1], Leo W. Perfect[1], Emma L. Dempster[2], Jonathan Mill[2], Jack Price[1]

[1]Neuroscience, King's College London, London, United Kingdom, [2]Epigenetics Group, University of Exeter Medical School, Exeter, United Kingdom

Human stem cell populations show clonal heterogeneity. Such phenotypic diversity has implications for development, and for the use of stem cells in regenerative medicine. We have previously demonstrated random or stochastic choice of allelic expression occurring in a subset of non-imprinted autosomal genes in genetically identical human neural stem cell clones derived from fetal brain. DNA methylation and a specific pattern of histone modifications are both associated with allelic choice. In this study, we asked what happens to stochastic allelic choice if the neural stem cell clones were epigenetically reprogrammed and neuralized? We carried out global allelic expression profiling of human induced pluripotent stem cells (hiPSC) derived from a previously characterised clonal neural stem donor. We also neuralized these cells and isolated neural stem cell clones. Results: We find that while imprinted genes remain imprinted, autosomal genes originally undergoing random or stochastic choice of allelic expression in the donor neural stem cells switch to biallelic expression in the epigenetically reprogrammed hiPSC state. Subsequent neuralization of the hiPSCs and clonal isolation of the neural stem cells show at least 0.75% of genes undergoing stochastic choice of allelic expression. The majority of these genes represent new loci when compared to the original donor neural stem cell, but functional annotation of these new genes show a strikingly similar profile to that seen in the original neural stem cell study, namely overrepresentation of membrane bound or cell surface genes, a number of which are of neurodevelopmental in function. We conclude that the diversity of neural stem cells generated by stochastic monoallelic expression is lost when the cells are reprogrammed, but re-established in a stochastic fashion when the reprogrammed cells are neuralized.

MOLECULAR MECHANISMS OF ASTROGLIA-TO-NEURON CONVERSION BY FORCED EXPRESSION OF PRONEURAL GENES

Giacomo Masserdotti[1], Sebastien Gillotin[3], Martin Irmler[2], Johannes Beckers[2], Francois Guillemot[3], Benedikt Berninger[4], Magdalena Goetz[1]

[A]Stem Cell Institute, [B]Institute for Experimental Genetics, [1]Helmholtz Zentrum, Munich, Germany, [2]Division of Molecular Neurobiology, National institution for Medical Research, London, United Kingdom, [3]Institute of Physiological Chemistry, University Medical Center Johannes Gutenberg University Mainz, Mainz, Germany

Direct conversion of differentiated cells into neurons is emerging as a promising alternative for cell-based therapies of neurodegenerative diseases, because it does not give rise to pluripotent intermediates. Yet little is known about the molecular mechanisms that induce direct neuronal reprogramming, thus limiting the development of more precise strategies aimed at obtaining pure, homogenous and specific neuronal subtypes.
To better understand the mechanisms underlying direct reprogramming, we employed astroglial cells as model system: in fact, they are distributed throughout the mammalian brain, thus representing a potential endogenous source of reprogrammable cells[1], and can be efficiently converted into functional neurons upon over-expression of two proneural genes, *Neurog2* and *Ascl1*[2,3] .
Astroglia cultures obtained from postnatal mouse cerebral cortex were transduced with retroviruses encoding an inducible system in which the cDNA of the proneural gene (either *Neurog2* or *Ascl1*) is fused to a modified estrogen receptor-binding domain (ERT2). Hence, the resultant protein is expressed but remains inactive unless cells are treated with tamoxifen, upon which inhibition is released. This allows for a temporally defined onset of the proneural gene's transcriptional activity. Indeed, *Neurog2*- and *Ascl1-ERT2*-transduced astrocytes generated neurons upon tamoxifen treatment, while no neurons were observed in control-treated *Neurog2*- or *Ascl1-ERT2*-transduced cells, thus providing an experimental system for further molecular analyses.
Unbiased transcription profile was performed on RNA extracted from astroglial cultures transduced with control viruses or *Neurog2*-(or *Ascl1*)-*ERT2* expressing viruses and treated with tamoxifen for 24 hours: interestingly, there is only a partial overlap between the genes induced by both Neurog2ERT and Ascl1ERT2, suggesting that the two proneural genes activate a different neurogenic program already at a very early stage of reprogramming, likely reflecting their capacity to direct astroglia towards distinct neuronal subtypes. On the other side, transcription factors downstream of both transcription factors are likely to contribute to the execution of a generic program of neurogenesis.
Indeed, loss-of-function experiments utilizing microRNAs against shared targets demonstrated their functional requirement for Neurog2-induced astroglia-to-neuron conversion; notably, these targets were not sufficient to reprogram cells on their own, but the combined expression could induce neuronal generation from postnatal astroglial cells, suggesting that each of them activates distinct and non-redundant branches of the Neurog2-induced program. These data provide a first insight into the early stages of direct reprogramming towards neurogenesis, highlighting the early activation of a neurogenic program, and identifying key factors required for the neuronal generation from postnatal astroglial cells.
This project was funded by Wellcome Trust and by the German Research Foundation (Deutsche Forschungsgemeinschaft).

EFFECTS OF SUBSTRATE TOPOGRAPHY ON THE FUNCTIONAL NEURONS PRODUCED BY DIRECT REPROGRAMMING OF FIBROBLASTS

Karina Kulangara[1], Andrew F. Adler[1], Hong Wang[2], Malathi Chellappan[1], Ellen Hammett[1], Ryohei Yasuda[2], Kam W. Leong[1]
[A]Biomedical Engineering, [B]Neurobiology, [1]Duke University, Durham, NC, United States

Cellular reprogramming holds tremendous potential for cell therapy and regenerative medicine. Recently fibroblasts have been converted into induced neurons (iN) by overexpressing the transcription factors *Ascl1*, *Brn2* and *Myt1L.* This presents an attractive cell source for combating neurodegenerative diseases. *In vivo* the microenvironment presents physical and biochemical cues that influence cellular behavior. It regulates cellular function ranging

from adhesion and migration to proliferation. Here we investigate how substrate topography influences reprogramming of fibroblasts to induced neurons. Polystyrene substrates imprinted with microgratings or circular posts were used with non-patterned polystyrene samples as controls. We observed a significant reduction of the number of neurites per soma on the 5 [[Unsupported Character - Symbol Font ]]m gratings topography compared to the smooth control. The corresponding average length of the neurites was 296.6 [[Unsupported Character - Symbol Font ]]m versus 174 [[Unsupported Character - Symbol Font ]]m. When comparing mRNA expression of cells on smooth substrates to 5 [[Unsupported Character - Symbol Font ]]m gratings we detected 81 differentially expressed genes, including ones implicated in neuronal differentiation and cell projection organization like artemin, netrin, slit3, Thy1, growth arrest specific protein 1, and sphingosine-1-phosphate receptor 1. As characterized by electrophysiology, the induced neurons obtained on 5 [[Unsupported Character - Symbol Font ]]m gratings and smooth substrates were functional. The average membrane potential of iNs on smooth substrates was similar to iNs on 5 [[Unsupported Character - Symbol Font ]]m substrates; with an average resting membrane potential of -76 mV for iNs on smooth and -82 mV for iNs on 5 [[Unsupported Character - Symbol Font ]]m gratings. This study advocates a role of cell-topography interactions in shaping iN identity. It also suggests the potential of applying topographical cues to optimize the microenvironment for various direct reprogramming processes.

BIOPHYSICAL REGULATION OF EPIGENETIC STATE AND CELL REPROGRAMMING

Timothy L. Downing[1], Jennifer Soto[1], Constant Morez[3], Timothee Houssin[4], Falei Yuan[1], Julia Chu[1], Ashley Fritz[2], Shyam Patel[1], David V. Schaffer[2], Song Li[1]

[A]Bioengineering, [B]Chemical Engineering, [1]University of California, Berkeley, Berkeley, CA, United States, [2]Biomedical Engineering, Ecole Polytechnique, Palaiseau, France, [3]University Lille Nord de France, F-59000, Lille, France

Cell reprogramming represents a major advancement in cell biology and has wide applications in regenerative medicine, disease modeling, and drug screening. Induced pluripotent stem cells can be produced from adult fibroblasts with the use of transcription factors and chemical compounds; however, the role of biophysical factors in cell reprogramming is not known. Here we show, for the first time, that biophysical cues, in the form of parallel microgrooves on the surface of cell-adhesive substrates, can significantly improve reprogramming efficiency and replace the effects of small molecule epigenetic modifiers. The mechanism behind this biophysical enhancement of cell reprogramming relies on mechanomodulation of epigenetic state -specifically, increases in histone H3 acetylation (AcH3) and histone H3 trimethylation (H3k4me3) on microgroove surfaces. Further investigation reveals that microtopography dramatically downregulates histone deacytylase (HDAC) activity and increases the expression of WD repeat domain 5 (Wdr5) protein -a subunit of H3 methyltransferase. Furthermore, microtopography promotes the upregulation of key epithelial-related genes, suggesting the initiation of a mesenchymal-to-epithelial transition, a required step in cell reprogramming. Disruption of actin-myosin contractility abolishes microtopographical regulation of epigenetics and cell reprogramming, confirming that the actin cytoskeleton is required for this epigenetic mechanomodulation. In addition, adult fibroblasts show a similar response on aligned nanofiber surfaces in cell reprogramming and histone modifications, providing additional evidence that various topographical cues can regulate cell reprogramming. Furthermore, micropatterning cells on islands of matrix proteins for tight regulation of cell shape demonstrates the critical role that cell deformation plays in actively changing epigenetic state. In summary, this study unravels how the microfeatures of cell-adhesive substrates can induce epigenetic modifications, which in turn lead to enhanced cell reprogramming. We believe this novel biophysical regulation of epigenetics and cell reprogramming has important implications in a number of complex biological processes and in the broad scope of cell biology.

GENETIC ENGINEERING OF PIG PLURIPOTENT CELLS USING A NOVEL GENE TARGETING TECHNIQUE.

JONGPIL KIM, YaeJu Sung, BakSoon Bong
Biomedical Engineering, Dongguk University, Seoul, Korea, Republic of

Several genetically modified pig models have been produced by combining conventional gene targeting methods with somatic cell nuclear transfer. However, these conventional techniques are inefficient in mammalian somatic cells and provide little control over the site specificity and rate of exogenous DNAintegration. Recent studies showed that genetic engineering of cells with TAL Effector nucleases (TALEN) is rapidly gaining popularity as a means to enhance the rate and specificity of DNA modifications in plant and animal cells. Here we examine the genetic modification in pigs by combining TALEN technology with induced pluripoetent stem cells. These studies will open the door to genome targeting with a precision that was not previously possible in a large animal model and provide important considerations for their safe and effective use in modification of the swine genome, and future innovative applications of this technology in pigs will be discussed.

PROGRAMMING THE HAIR FOLLICLE STEM CELL NICHE IN UNCOMMITTED SKIN FIBROBLASTS

Carlos Clavel, Amelie Rezza, Michael Rendl
Developmental & Regenerative Biology, Mount Sinai School of Medicine, New York, NY, United States

Cell-based regenerative therapies are still unavailable to restore hair follicles in hair loss patients and to generate new hair follicles in burn victims or patients with other debilitating skin disorders. Currently, there is a lack of know-how to expand fully functional DP cells in the culture dish for hair inductive cell transplantations. To generate sufficient cell quantities for hair regenerative therapies we sought to reprogram regular fibroblasts into DP cells. Overexpression of previously identified DP signature transcription factors (TFs) in freshly isolated fibroblasts in combination with inhibitors of histone modifiers significantly upregulated several DP signature genes. Furthermore, 3D aggregation clustering of TF overexpressing fibroblast lines isolated from double-transgenic Sox2-GFP/Lef1-RFP reporter mice activated reporter activity and induced the DP molecular identity. Our preliminary data suggest that the right combination of DP TFs can reprogram DP niche fate in regular fibroblasts that can potentially be utilized in future hair restoration efforts.

W-2212

MODELING PARKINSON'S DISEASE USING INDUCED NEURAL PRECURSOR CELLS.

Bronwen J. Connor, Rebecca Pearman, Erin Firmin, Kathryn S. Jones
Pharmacology, University of Auckland,, Auckland, New Zealand

To date, our ability to effectively study and treat Parkinson's disease (PD) has been limited by lack of access to affected human neurons. This restricts the ability to obtain important insights into PD pathology, progression and mechanism, preventing early diagnosis and the development of successful treatment strategies. To overcome this we propose to use direct reprogramming of adult human dermal fibroblasts (HDFs) to generate neural precursor cells and subsequently mature human dopaminergic (DA) neurons to facilitate the study of PD. In support of this proposal, we have demonstrated the ability to transform adult HDFs obtained from PD patients with the LRRK2 mutation directly into neural precursor-like (iNP) cells. Ectopic expression of the neural genes *SOX2* and *PAX6* to either normal- or PD- derived adult HDFs allowed the generation of iNP colonies expressing a wide range of neural stem and pro-neural genes. Most importantly, iNP colonies expressed a range of mesencephalic markers including *ASCL1, NGN2, NURR1, FOXA1, PITX3, NKX2.2* and *LMX1A*. Upon differentiation, iNP cells gave rise to neurons expressing multiple neuronal markers, including the dopaminergic marker tyrosine hydroxylase (TH). To successfully develop a human cell model of PD it is necessary to obtain high yields of dopaminergic neurons. We therefore optimized a protocol for the efficient generation of dopaminergic neuronal cultures from normal and PD iNP cells. This protocol generated an enhanced yield of TH-positive neurons (~50-70%) following differentiation of human iNP cells compared to previous protocols utilizing iPS cells (~10-30%). These results demonstrate that direct reprogramming of

PD patient-derived HDFs to iNP cells provides an efficient mechanism for the generation of dopaminergic neurons for PD modeling and drug development.

TRANSCRIPTION FACTORS MYOCD, SRF, MESP1 AND SMARCD3 SIGNIFICANTLY ENHANCE THE CARDIO-INDUCING EFFECT OF GATA4, TBX5, AND MEF2C DURING DIRECT CELLULAR REPROGRAMMING

Nicolas Christoforou[1], Malathi Chellappan[1], Andrew F. Adler[1], Robert D. Kirkton[1], Terry Wu[1], Russell C. Addis[2], Nenad Bursac[1], Kam W. Leong[1]

[1]Biomedical Engineering, Duke University, Durham, NC, United States, [2]University of Pennsylvania, Philadelphia, PA, United States

Transient over-expression of defined combinations of master regulator genes can effectively induce cellular reprogramming: the acquisition of an unpredicted phenotype from a differentiated cell lineage. This can be of particular importance in cardiac regenerative medicine as the heart lacks the capacity to heal itself, but simultaneously contains a large pool of fibroblasts. In this study we used a multi-component experimental approach to determine the cardio-inducing capacity of ten transcription factors to actuate cellular reprogramming of mouse embryonic fibroblasts into cardiomyocyte-like cells: Mesp1, SMARCD3, MYOCD, SRF, NKX2-5, HAND1, HAND2, GATA4, TBX5, MEF2C. Over-expression of transcription factors MYOCD and SRF alone or in conjunction with Mesp1 and SMARCD3 significantly enhanced the basal but necessary cardio-inducing effect of the previously reported GATA4, TBX5, and MEF2C. In particular, combinations of the five or seven transcription factors significantly enhanced the activation of cardiac reporter vectors, and induced an upregulation of cardiac-specific genes. Global gene expression analysis also demonstrated a significantly greater cardio-inducing effect when the transcription factors MYOCD and SRF were utilized. Detection of cross-striated cells was highly dependent on the cell culture conditions and was enhanced by the addition of valproic acid and JAK inhibitor. Importantly, although we detected Ca2+ transient oscillations in the reprogrammed cells, we did not detect significant changes in resting membrane potential or spontaneously contracting cells. This study further elucidates the cardio-inducing effect of the transcriptional networks involved in cardiac cellular reprogramming, with the aim of fine-tuning this approach and ultimately translating into robust cardiac regenerative therapies.

W-2214

SMALL MOLECULE ENHANCED DIRECT CONVERSION OF ADULT DERIVED MOUSE AND HUMAN PATIENT FIBROBLASTS INTO SPINAL MOTOR NEURONS

Andre M. Blumenstein[1], Justin Ichida[2], Esther Son[1], Jeremy Toma[3], Brian Wainger[4], Anthony Arvanites[1], Lance Davidow[1], Kaitlin Sandor[1], Nick Atwater[1], Clifford Woolf[5], Victor Rafuse[3], Kevin Eggan[1], Lee Rubin[1]

The mammalian nervous system consists of a large variety of unique neuronal subtypes, some of which are affected in particular neurodegenerative diseases. In the past several years, there has been a great deal of interest in establishing methods of producing large numbers of these neuronal types starting from patient biopsies. Generation of induced pluripotent stem cells (iPSCs) followed by neuronal differentiation is a widely employed technique, but, more recently, direct differentiation methods -generating neurons from fibroblasts without the need for an iPSC intermediate -- have been established. One advantage of direct differentiation is that it can lead to more rapid production of neurons, but this method can be inefficient, especially when starting from adult rodent or human fibroblasts.

We attempted to address this issue by deriving a rapid and effective protocol for producing induced spinal cord motor neurons (iMNs). We performed a chemical screen of 400 selected compounds to identify ones that might capable of improving the number of iMNs that appear as a result of transcription factor mediated reprogramming, starting from tail tip fibroblasts of two-month-old Hb9::GFP mice. After three weeks, compounds were scored based on the appearance of GFP+ iMNs, and secondary assays were then performed on potential hits. We found that small molecule inhibition of Activin signaling improved iMN production over 40-fold by stimulating the survival of both early reprogramming intermediates and of the resulting iMNs. Normal neural progenitors were not generated, though. Surprisingly, the small molecules were as, or more, effective in enhancing the production of human iMNs. In addition, we found that inhibiting this pathway was also effective in helping to stimulate differentiation of neurons of other subtypes, including induced forebrain neurons. The combination of defined transcription factors and small molecule enhancers can now be used in efficient and rapid production of neurons from multiple patient biopsies.
Supported by grants from the NINDS, the Harvard Stem Cell Institute and the New York Stem Cell Foundation.

ENHANCED GENERATION OF INDUCED DOPAMINERGIC NEURONS FOR TRANSPLANTATION STUDIES

Ulrich Pfisterer[1], Shane Grealish[1], Maria Pereira[1], Shong Lau[1], James Wood[2], Martin Lundblad[1], Olle Lindvall[2], Malin Parmar[1]

[A]Department of Experimental Medical Sciences, [B]Department of Clinical Sciences, [1]Wallenberg Neuroscience Ctr, Lund, Sweden

Overexpression of three transcription factors Ascl1, Brn2 and Myt1L (ABM) efficiently converts human embryonic as well as post-natal fibroblasts into functional neurons, termed human induced neural (hiN) cells. We have shown that simultaneous expression of the additional transcription factors Lmx1a and Foxa2 results in a dopaminergic cell fate in hiN cells.
Performing a systematic screen and following a novel transduction strategy, a new combination of transcription factors has been identified that leads to a 10-fold increased frequency of DA hiN cell formation from embryonic and postnatal fibroblasts. The function of DA hiN cells in vitro has been determined by DA release and electrophysiology. Current work focuses on the investigation of survival and function of DA hiN cells in rodent models of PD as well as their gene expression profile.
Our data demonstrate an improved strategy to increase the generation of functional DA neurons from human fibroblasts, which survive up to 12 weeks upon grafting into adult rodents. The ability to direct hiN cells towards specific subtypes of neurons at higher frequency as well as to graft reprogrammed cells offers exciting future possibilities to generate patient-specific neurons for disease modeling and brain repair.

ENHANCED DIRECT CONVERSION INTO HEPATOCYTES BY ADDITIONAL TRANSCRIPTION FACTOR

Kyung Tae Lim[1], Seung Chan Lee[1], Su Yeon An[2], Yu Jin Jang[2], Jong Hun Kim[1], Kyoung-Jin Oh[3], Tae Hwan Kwak[1], Seung-Hoi Koo[3], Jong-Hoon Kim[2], Dong Wook Han[1]

[1]Dept. of Stem Cell Bilogy, School of Medicine, Konkuk University, Seoul, Korea, Republic of, [2]Lab. of Stem Cell Biology, Division of Biotechnology, College of Life Sciences and Biotechnology, Korea University, Seoul, Korea, Republic of, [3]Division of Biochemistry and Molecular Biology, Dept. of Molecular Cell Biology and Samsung Biomedical Research Institute, Sungkyunkwan University, Seoul, Korea, Republic of

Recent advances in stem cell biology have shown that terminally differentiated somatic cells can be directly converted to the different types of somatic cells with defined sets of transcription factors without going through a pluripotent state. Recently, it was demonstrated that the combinations of 2 (Hnf4a with one of the Foxa1, Foxa2 and Foxa3) or 3 (Hnf1a/Foxa2/Gata4) hepatic transcription factors could directly convert fibroblasts into functional hep-

atocytes, namely induced hepatocytes (iHeps). However, both the low conversion rates and the unraveled mechanism of direct conversion into iHeps still remain to be elusive. Here, we show that additional transcription factor together with previously described hepatic factors dramatically enhance the direct conversion process into iHeps. Furthermore, in the presence of additional factors, Hnf4a alone could directly induce hepatocyte fate on fibroblasts within 5 days. Directly converted iHeps closely resemble both iHeps generated from the previous combinations and primary hepatocytes in a number of characteristics such as morphology, marker expression, epigenetic status, global gene expression pattern and the functionality. Therefore, our data suggest that additional transcription factor dramatically enhance the direct conversion of fibroblasts into iHeps and also that additional factor could replace some of the hepatic factors.

W-2217

EXPLORING NOVEL PATHWAYS OF NEURAL REPROGRAMMING BY INSTRUCTIVE FACTORS AND PHARMACOLOGICAL INTERVENTION

Marc Thier, Woersdoerfer Philipp, **Frank Edenhofer**
University of Bonn, Bonn, Germany

Transcription factor-driven reprogramming of somatic cells has been shown to yield neurons, cardiomyocytes, neural as well as hepatocyte progenitors, demonstrating that direct conversion of somatic cells developed into a new paradigm for both regenerative medicine and disease modeling. Recently, we demonstrated the direct derivation of neural stem (NS) cells from mouse fibroblasts employing a modified Yamanaka-type reprogramming paradigm. Retroviral transduction of Sox2, Klf4, c-Myc and timely restricted activation of Oct4 was used to initiate dedifferentiation of fibroblast cells and 19 days post infection we observed neurosphere-like colonies that could be readily isolated and clonally expanded both in sphere and adherent cultures. Such induced NS (iNS) cells are able to differentiate into all three neural lineages, neurons, astrocytes as well as oligodendrocytes. Fibroblast-derived iNS cells exhibit clonal growth and maintain their marker expression profile and differentiation capability over prolonged expansion (>50 passages). Transduction of neurogenic transcription factors as well as application of small molecule inhibitors were tested to explore alternative pathways of direct conversion. By this, we generated alternative neural progenitor populations with modified differentiation potentials. Molecular mechanisms underlying reprogramming and therapeutic value of reprogrammed cells will be discussed. We expect converted somatic stem cells such as iNS cells to provide a safe and robust, virtually unlimited source of patient-specific cells for future applications in regenerative medicine and disease modeling.

W-2218

DIRECT CONVERSION OF MOUSE FIBROBLASTS INTO OLIGODENDROCYTE PROGENITOR CELLS BY DEFINED TRANSCRIPTION FACTORS

Hyunah Lee, Myung Rae Park, Seung Hun Lee, Soo Yong Park, Man Sze Wong, Jeong Beom Kim
Max Planck Parter Group - Molecular Biomedicine Laboratory, Hans Schöler Stem Cell Research Center, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

Cell fate can be converted between different somatic lineages without passing pluripotent state. This advanced method provides an alternative to using pluripotent stem cells and rule out the concern of tumorigenicity by undifferentiated pluripotent stem cells during differentiation. Previous studies have shown that defined transcription factors can convert the terminally differentiated somatic cells to other cell types, including induced neural stem cells, hepatocytes, or cardiomyocytes. This strategy provided a new approach toward the regenerative medicine and stem cell therapy for degenerative diseases.
Among many neurodegenerative diseases, oligodendrocyte dysfunction is caused by defect of myelination, including multiple sclerosis, cerebral palsy, and leukodystrophies. Mechanisms these diseases are still unknown and transplantation of myelin-forming cells into injured CNS can be the only possible therapeutics for myelin repair. In this

study, we suggest that generating oligodendrocyte progenitors is potential strategy to develop clinical application for myelin disorders.
Here, we established the efficient derivation of induced oligodendrocyte progenitor cells (iOPCs) from mouse fibroblasts by inducing defined transcription factors. Importantly, these iOPCs are homogenous, self-renewal, and multipotent as somatic stem cells. iOPCs exhibit morphological and molecular characteristics of OPCs such as marker expression. iOPCs can also differentiate into myelin-forming oligodendrocytes expressing mature oligodendrocyte marker as well as in vivo functionality.
We conclude that terminally differentiated cells can be directly converted into functional iOPCs by defined transcription factors. The generation of iOPCs may provide insights into future stem cell therapies for CNS injury and degeneration.

W-2221

REMOTE CONTROL OF NEURONAL FIRING APPLICATION ON MOUSE INDUCED DOPAMINERGIC NEURONAL(IDAN) CELLS

Maria Teresa Dell'Anno[1], Damiana Leo[2], Elena Dvoretskova[2], Ilda Theka[1], Alexander Dytiatev[2], Raul Gainetdinov[2], Bryan Roth[3], Vania Broccoli[1]
[1]Neuroscience, San Raffaele Scientific Institute, Milano, Italy, [2]Neuroscience, Italian Institute of Technology, Genova, Italy, [3]University of North Carolina, Chapell hill, NC, United States

Remote control of neuronal firing may currently be achieved through two well validated approaches: optogenetics and pharmacogenetics. Both the methods allow a detailed analysis of the elecrophysiological properties of discrete neuronal subpopulations genetically modified to express either light-gated ion channels or mutant G-protein coupled receptors, respectively. In the present work we used a pharmacogenetic tool, known as DREADDs, to study the properties of newly reprogrammed cells and compare them with primary cell culture. DREADDs are human muscarinic receptors designed to be a) non- responding to their native ligand and b) activated exclusively by a biologically inert synthetic drug called CNO (Clozapine- N-Oxide). Here two DREADDs known to modulate the neuronal excitability have been investigated: hM3Dq and hM4D. It has already been demonstrated in several neuronal populations that the activation of hM3Dq by CNO promotes the enhancement of neuronal firing, whereas the activation of hM4D induces silencing. We sought to apply DREADDs technology on two kinds of cells: mesencephalic dopaminergic primary neurons and dopaminergic neuronal cells obtained through direct reprogramming (iDAN cells).Whole-cell patch-clamp recordings show that application of CNO on DREADDs expressing cells is able to elicit a significant modulation of action potentials frequency with a similar pattern either in primary cell culture or in iDAN cells.

W-2222

TRANSCRIPTIONAL AND FUNCTIONAL REPROGRAMMING OCCUR WITHOUT CORRESPONDING CHANGES IN DNA METHYLATION DURING THE DIRECT CONVERSION OF FIBROBLASTS INTO MOTOR NEURONS

Justin Ichida[1], Kendell Clement[2], Brandi Davis-Dusenberry[2], Andre Blumenstein[2], Esther Son[2], Jeremy Toma[3], Brian Wainger[4], Samuel Alworth[5], Clifford Woolf[4], Victor Rafuse[3], Lee Rubin[2], Alexander Meissner[2], Kevin Eggan[2]
[1]Stem Cell Biology and Regenerative Medicine, University of Southern California, Los Angeles, CA, United States, [2]Harvard University, Cambridge, MA, United States, [3]Dalhousie University, Halifax, NS, Canada, [4]Harvard University, Boston, MA, United States, [5]DR Vision, Seattle, WA, United States

Direct reprogramming provides the intriguing ability to change the identity of a cell while preserving its genetic information. Recent studies suggest select transcriptional regulators can reprogram cells not only to pluripotency, but also to specific somatic cell states, an approach that could have significant translational utility. However, while

several studies have evaluated the integrity of iPSCs, it remains unclear if somatic cells generated by direct reprogramming achieve complete transcriptional, functional, and epigenetic conversion.
To this end, we have evaluated these aspects of lineage conversion in induced motor neurons (iMNs) generated from mouse and human fibroblasts using MN-specific transcription factors. Because iMNs are a specific subtype of neuron that have a well-defined counterpart in mice and humans, we can directly compare their molecular and functional properties.
We first compared the transcriptional profiles of flow-purified Hb9::GFP+ mouse iMNs, bona fide spinal cord MNs, mESC-derived MNs, miPSC-derived MNs, as well as fibroblasts and pluripotent stem cells using genome-wide RNA seq. While all MN samples clustered together, iMNs were more similar to spinal cord MNs (Pearson coefficient = .90) than were stem cell-derived MNs (Pearson coefficient = .85-86). While ~4500 genes were differentially expressed between iMNs and fibroblasts, only 500 genes differed between iMNs and spinal cord MNs and ~700 genes differed between stem cell-derived MNs and spinal cord MNs. Thus, the transcriptional profile of iMNs is highly similar to that of spinal cord MNs while that of stem cell-derived MNs is less similar, indicating that transcriptional reprogramming is essentially complete in iMNs.
To investigate the level of epigenetic reprogramming in iMNs, we mapped their genome-wide DNA methylation profile by bisulfite sequencing. In contrast to transcription, methylation differed significantly between iMNs and spinal cord MNs within and outside of promoter regions while methylation in stem cell-derived MNs was similar to that of spinal cord MNs. During reprogramming, the iMN profile shifted away from the fibroblast pattern but by day 25 was equidistant between fibroblasts and spinal cord MNs. Thus, transcriptional reprogramming precedes and does not require full epigenetic reprogramming.
Next, we evaluated the functional properties of iMNs. They possessed full electrophysiological function and formed neuromuscular junctions in which we readily observed iMN-induced muscle contraction. In addition, mouse iMNs engrafted correctly into chick spinal cord upon transplantation. To evaluate their utility in modeling amyotrophic lateral sclerosis (ALS), in which motor neurons degenerate, we produced human iMNs containing familial ALS mutations in the gene SOD1. In culture, the ALS iMNs degenerated >2-fold faster than those from 12 healthy individuals and exhibited marked hyperexcitability, which has been observed in SOD1 mutant mice and patients and is believed to drive neurodegeneration. Moreover, iMNs from an additional 4/4 familial and 6/21 sporadic patients degenerated rapidly in culture similarly to the SOD1 mutant iMNs. Thus, iMNs possess all measureable functional qualities of motor neurons.
These results show that full transcriptional and functional reprogramming can occur before and without full epigenetic reprogramming during direct conversion to adult somatic cell types.

W-2223

NEW TRANSCRIPTION FACTOR CODES FOR DIRECT REPROGRAMMING OF FIBROBLASTS TO SPECIFIC NEURAL SUBTYPES

Rachel K. Tsunemoto[1], Andrew F. Adler[2], Pavel A. Chubukov[3], Kristin K. Baldwin[3]
[1]University of California San Diego, San Diego, CA, United States, [2]Duke University, Durham, NC, United States, [3]The Scripps Research Institute, La Jolla, CA, United States

Remarkably, recent studies have shown that functional neurons can be generated directly from fibroblasts by ectopically expressing specific combinations of transcription factors or microRNAs. These induced neurons (iNs) will be most useful for disease modeling or therapy if it is possible to control their subtype identity and/or developmental stage in vitro. At present it is not clear how many different neural lineages can be generated by direct reprogramming. To address this question, we have used a mouse line that allows us to screen for the generation of neurons that express the Pcdh21 gene, which is highly enriched in a few rare neuronal subtypes, including the excitatory olfactory bulb mitral and tufted projection neurons. We find that Pcdh21-expressing iNs are not produced using previously published combinations of factors, but that these neurons arise with high efficiency using two new factor combinations. These Pcdh21-expressing iNs exhibit spontaneous and evoked patterns of neural activity and express other genes consistent with a mitral and tufted neuronal identity. We will present additional data to charac-

terize the endogenous neuronal subtypes and developmental stage that these Pcdh21-expressing iNs most closely resemble.

W-2224

INVESTIGATING GENETIC PREDISPOSITION TO ADDICTION WITH INDUCED NICOTINIC NEURONS

Joel W. Blanchard, Kevin T. Eade, Kristin Baldwin
Scripps Research Institute, La Jolla, CA, United States

Tobacco addiction is the leading cause of death in the United States, and is attributed to nearly 5 million deaths worldwide each year. Nicotine is the principle-reinforcing agent in tobacco, exerting its addictive effect on the brain through nicotinic acetylcholine receptors. Genome-wide association studies have identified SNPs in nicotinic acetylcholine receptors that strongly correlate with heavy smoking, nicotine dependence, lung cancer, and heart disease. Mouse studies established that a small midbrain structure, known as the medial habenula (mHb), is responsible for sensing and regulating the amount of nicotine intake, suggesting it may play a major role in human addictions. Although the medial habenula and genetics predispose individuals to nicotine addiction, no cessation therapy selectively targets either. A major limitation to developing mHb and genetically targeted therapies is the absence of in vitro models enabling such studies. To address these limitations we have developed methods employing stem cell technologies that convert mouse fibroblasts to neurons that resemble those of the medial habenula, express nicotinic receptors, and respond to nicotine. We are optimizing these findings by determining the minimal set of transcription factors and growth conditions required for efficiently converting mouse fibroblasts to mature induced nicotinic neurons (iNNs). Once optimal methods for generating iNNs are established, we will examine how common genetic elements that strongly correlate with heavy smoking impair nicotine sensing and response in iNNs. These studies will deliver an in vitro model of medial habenula neurons and establish differences in nicotine sensing and response due to genetic elements known to predispose individuals to nicotine addiction. This work will lay the foundation for future studies aimed at identifying aberrant intracellular signaling pathways in mHb neurons that mediate addiction, and also establish in vitro assays of addiction that can be used to screen for new classes of genetically tailored cessation therapies.

HYPOMETHYLATION OF DNMT1 GENE REMOVES THE BARRIER OF IPSC REPROGRAMMING

Julia Chung, Camille Sindhu, Zachary Smith, Atsushi Into, Alexander Meissner, Kevin Eggan
Stem cell and regenerative biology, Harvard University, Cambridge, MA, United States

Reprogramming somatic cells into induced pluirpotent stem cells (iPSCs) by defined transcription factors holds great potential for biomedicine. However, reprogramming process retains slow kinetics and low efficiency. Reprogramming of somatic cells into iPSCs resets the epigenome to embryonic-like state which remains hypomethylation in pluripotentcy genes. We hypothesized that hypomethylation of DNA methyltransferase 1 (Dnmt1) gene might increase the reprogramming potential and perturb a blockade of iPSC reprogramming. Here, we have generated an allelic series of *Dnmt1* MEFs, which have differentially modulated *Dnmt1* expressions, and investigated the reprogramming efficiency. We found that a 90% reduction in the *Dnmt1* level enhances the dynamic of reprogramming over 4-folds, although it causes cell death in hypomorphic MEFs. Furthermore, DNA demethylation synergized with histone demethylation increases their conversion rates up to 10-folds. At the epigenetic level, methylation levels of *Oct4* enhancer are reduced in hypomrophic MEFs, indicating that *Dnmt1* demethylation unravels the repressive effect in the *Oct4* regions. Our findings demonstrate that *Dnmt1*demethylation can increase reprogramming potential of somatic cells. Collectively, our data offer new insights into the nature of epigenetic events inherent to cellular reprogramming.

INDUCTION OF PLURIPOTENCY IN PRIMORDIAL GERM CELLS (PGC) BY INHIBITION OF TGFB SIGNALLING PATHWAY

Farnoosh Attari[1], Houri Sepehri[1], Abdolhossein Shahverdi[2], Hossein Baharvand[2]
[1]*Department of Animal Biology, School of Biology and Center of Excellence in Phylogeny of Living Organisms, College of Science, University of Tehran, Tehran, Iran, Islamic Republic of,* [2]*Department of Stem Cells and Developmental Biology, Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Iran, Islamic Republic of*

Introduction: Primordial germ cells (PGCs) have the ability to reprogram into a pluripotent state, named embryonic germ cells (EG) in vitro. In Comparison to iPS cell derivation, the EG cell formation is more efficient and has a shorter culture period than somatic cell reprogramming, furthermore no exogenous genetic manipulations is required in the process. Therefore, EG

cell formation provides a good model to analyze mechanisms by which committed cells acquire pluripotency. So in this study we have tried to induce reprogramming of PGCs toward EG cells with suppressing TGF-β signaling and simultaneous inhibition of ERK pathway with the aim of eliminating usage of GSK3 inhibitor that was previously reported for reprogramming of PGCs. Materials and Methods: To obtain a better robust derivation protocol, we have attempted to identify small molecules (SMs) that induce reprogramming of PGCs in culture. PGCs were isolated and cultured with the presence of different SMs. The emerged EG colonies were picked and expanded in the mentioned medium. The obtained cell lines were further analyzed by immunofluorescent staining, directed differentiation ability and teratoma formation. Results: In this study we have shown that PGCs could be reprogrammed, maintain and expand under feeder and serum free chemically defined conditions by dual inhibition of two signaling pathway and demonstrated that there is no need for GSK3 inhibition for achievement of EG cells from PGCs. Discussion: Here we report that PGCs from different embryo ages (8.5-12.5) can be reprogrammed into pluripotent stem cells through manipulating signaling pathways under chemically modified culture condition, regardless of animal genetic background. Future studies will determine whether generation of EG cells by inhibiting mentioned pathways could be applied to other mammals, especially human and Rat.

TRANSFORMATION OF PORCINE PRIMORDIAL GERM CELLS INTO EMBRYONIC GERM CELLS UNDER APPROPRIATE CULTURE CONDITION WITH SMALL MOLECULES

Yanjie Guo, Shiqiang Zhang, Huayan Wang
Dept. Biotechnology, Northwest A&F University, Yangling, China

Embryonic germ (EG) cells are derived from primordial germ cells (PGCs) in vitro under the appropriate culture conditions. EG cells retain the pluripotent and proliferative capacity, which is thought to be equivalent to that of mouse embryonic stem cells. The difficulties of isolating and maintaining EG cells in vitro have restricted their availability for experimental use. To optimize the culture condition, porcine PGCs were isolated from porcine fetus at day 24 of gestation and cultured in media with the different treatments. Three elements, including culture media, feeder cells and small molecules, have been detected to influence the growth of porcine PGCs. When cultured in the basal medium that consists of DMEM supplemented with FBS, LIF, bFGF and SCF for 7 days, PGC clones were investigated by the alkaline phosphatase (AP) activity. The EG cells derived from AP positive colonies represented the naïve-like morphology and were able to propagate on mouse embryonic fibroblasts(MEF) feeder for up to 15 passages, retaining the undifferentiated features. However, EG cells cultured on feeders of porcine embryo fibroblasts (PEF) and stromal cells from mesonephron region, respectively, were unstable and differentiated rapidly. In addition, EG cells were positive for OCT4, SOX2 and SSEA-4, but negative for SSEA-1 by immunofluorescence staining. Quantitative RT-PCR showed that expression of OCT4, NANOG and EpCAM was significantly higher in EG cells than that in porcine somatic cells. We found that the basal medium supplemented with inhibitors of MEK (PD0325901), GSK3β (CHIR99021) and TGFβ (SB431542) could greatly enhance the proliferation of porcine PGC in vitro and clone formation, which were 40 folds higher than that in basal condition. In basal medium added with SB431542 only, the number of PGC clones was elevated ~20 folds. However, basal medium with either PD0325901 or CHIR99021 was just slightly influence the rate of clone formation, suggesting that SB431542 played a critical role in forming the AP positive clones. In summary, we established an efficient culture condition to maintain porcine PGCs growth in vitro, and to facilitate the EG cells derivation and further investigation on porcine pluripotent cells.

TARGETED MANIPULATION OF CELL CYCLE AND GENOME STABILITY REGULATORS OVERCOMES RESISTANCE TO REPROGRAMMING IN CELLS FROM FANCONI ANEMIA PATIENTS

Timothy M. Chlon[1], Elizabeth E. Hoskins[1], James M. Wells[2], Susanne I. Wells[1]
[A]Experimental Hematology, [B]Developmental Biology, [1]Cincinnati Children's Hospital, Cincinnati, OH, United States

Fanconi Anemia (FA) is a genetic disease that results from inactivating mutations in one of 15 known genes that are part of a DNA repair pathway. Two recent studies have revealed that cells from FA patients are refractory to somatic cell reprogramming under standard conditions, unless the mutated gene is complemented. One of these studies found that culturing FA cells in hypoxia, which is known to increase reprogramming efficiency in normal cells, also increased the efficiency of iPS colony formation in the context of FA. While an increase in DNA damage and senescence markers was noted during reprogramming in FA cells compared to normal cells, the molecular mechanism by which the FA pathway contributes to reprogramming remains to be elucidated. It is hypothesized that somatic cell reprogramming induces DNA damage, perhaps through the generation of reactive oxygen species (ROS), and that the inability of FA cells to repair this damage results in senescence. The p53 tumor suppressor is known to respond to increased DNA damage by stalling cell cycle progression and even inducing cell death. Inhibition of p53 in normal cells has been shown to dramatically increase the efficiency of reprogramming, indicating that p53 signaling inhibits reprogramming. In this study, we hypothesized that inhibition of p53 or other cell cycle and genome stability regulators would allow FA cells to overcome the block to reprogramming.
We used small molecule inhibitors and retrovirally-expressed oncogenes to target various cell cycle and genome stability regulators during FA cell reprogramming. Our initial results indicate that inhibition of p53, using either the human papillomavirus oncogene E6, the p53 dominant-negative protein p53dd, or p53 specific shRNAs induces iPSc colony formation in FA patient cells. Additionally, treatment with rapamycin or the ROCK inhibitor Y-27632 also induced robust colony formation. Reprogrammed colonies were identified by morphology and positive staining for Tra-1-60 and alkaline phosphatase activity. Our results indicate that multiple pathways can be manipulated to overcome the deficiency of reprogramming in FA cells, and highlight the need to study the consequences of FA pathway loss on cell proliferation and self-renewal in pluripotent stem cells.

HIGHER ORDER CHROMATIN STRUCTURE SHAPES THE GENOMIC ABERRATION LANDSCAPE OF PLURIPOTENT STEM CELLS

Junjie Lu[1], Hu Li[2], Ming Hu[3], Jun S. Liu[3], James J. Collins[2], Paul H. Lerou[1]
[1]Department of Newborn Medicine and Division of Genetics, Brigham and Women's Hospital / Harvard Medical School, Boston, MA, United States, [2]Howard Hughes Medical Institute, Department of Biomedical Engineering and Center for BioDynamics, Boston University, Wyss Institute for Biologically Inspired Engineering, Harvard University, Boston, MA, United States, [3]Department of Statistics, Harvard University, Cambridge, MA, United States

Genome organization is intrinsically connected to various functions, including DNA replication, damage repair and genomic aberrations. To investigate the functional effects of genome organization and reorganization during nuclear reprogramming, we mapped one major type of genomic aberration - copy number variations (CNVs) detected by SNP arrays - from low and high passage induced pluripotent stem cells (iPSCs) to megabase-sized chromatin domains defined by DNA replication timing and Hi-C chromatin interactions of the same matched cell types. We found that CNVs are not randomly distributed throughout the genome, consistent with recent reports on the relationship between certain genomic variations in cancer cells and DNA replication timing. In wild type (WT) iPSCs, CNV gains enrich in early replicating domains and open chromatin region while losses enrich in late replicating and closed chromatin regions. However in iPSCs derived from Ataxia-Telangiectasia patients (ATM iPSCs), where DNA damage response and repair (DDR) system is deficient, this trend is markedly different. In low passage ATM iPSCs, gains tend to affect late replicating domains while losses enrich in early domains. However CNVs in higher passage ATM iPSCs have a similar trend as those detected in WT cells. Moreover, we found that the appearance of CNVs is related to the changes in replicating timing program between somatic cells and iPSCs. Our results demonstrate that the dynamic mutational landscape of iPSCs is shaped by genome organization and provide important insights into the effect of genome reorganization and the roles of DDR during reprogramming.

GENERATION OF GGTA1 BIALLELIC KNOCKOUT PIGS VIA ZINC-FINGER NUCLEASES AND SOMATIC CELL NUCLEAR TRANSFER

Haide Chen[1], Lei Bao[2], Lei Xiao[1]
[1]*College of Animal Science, Zhejiang University, Hangzhou, China,* [2]*Shanghai Institute of Biochemistry and Cell Biology, Shanghai, China*

Genetically modified pigs are valuable models of human disease and donors of xenotransplanted organs. Conventional gene targeting in pig somatic cells is extremely inefficient. Zinc-finger nuclease (ZFN) technology has been shown to be a powerful tool for efficiently inducing mutations in the genome. However, ZFN-mediated targeting in pigs has rarely been achieved. Here, we used ZFNs to knock out the porcine α-1, 3-galactosyl-transferase (*GGTA1*) gene, which generates Gal epitopes that trigger hyperacute immune rejection in pig-to-human transplantation. Primary pig fibroblasts were transfected with ZFNs targeting the coding region of *GGTA1*. Eighteen mono-allelic and four biallelic cell clones were obtained after drug selection with efficiencies of 23.4% and 5.2%, respectively. The biallelic cells were used to produce cloned pigs via somatic cell nuclear transfer (SCNT). Three *GGTA1* null piglets were born, and one knockout primary fibroblast cell line was established from a cloned fetus. Gal epitopes on *GGTA1* null pig cells were completely eliminated from the cell membrane. Functionally, *GGTA1* knockout cells were protected from complement-mediated immune attacks when incubated with human serum. This study demonstrated that ZFN is an efficient tool in creating gene-modified pigs. *GGTA1* null pigs and *GGTA1* null fetal fibroblasts would benefit research and pig-to-human transplantation.

OPTIMISED DERIVATION OF INDUCED PLURIPOTENT STEM CELLS FROM HUMAN AND MOUSE GRANULOCYTES

Jaber Firas, Christian M. Nefzger, Sue Mei Lim, Jose M. Polo
Anatomy and Developmental Biology, Monash University, Melbourne, Australia

Like Embryonic stem cells (ESCs), induced pluripotent stem cells (iPSCs) are characterised by their ability to differentiate into any cell type of the body. However, unlike ESCs, iPSCs can be derived by reprogramming mature cells via the forced expression of OCT4, SOX2, KLf4 and c-MYC. Accordingly, iPSCs circumvent ethical issues attached to ESC research and have a vast therapeutic potential for disease modelling, pharmaceutical screening and autologous cell therapy. The most common source for iPSC derivation is skin fibroblasts. However, from a clinical point of view, skin fibroblast may not be the ideal cell type, since their acquisition requires an invasive approach such as skin biopsies. Peripheral blood (PB), on the other hand, could be an easy source of patient specific iPSCs because of the availability of minimally invasive collection methods. Granulocytes in particular are highly abundant in PB and constitute 40-60% of all white blood cells. Furthermore, fluorescence activated cell sorting allows the isolation of these cells at high purity, thus iPSCs derivation from granulocytes could provide an alternative to fibroblast derived iPSCs. Previous study succeeded in producing iPSC colonies from murine granulocytes and human mononuclear blood cells but with a low efficiency. Hence, the aim of this study is to increase the efficiency of granulocyte reprogramming into iPSCs from murine and human sources. As granulocytes display poor survival under traditional reprogramming conditions, we investigated the influence of haematopoietic growth factors to stabilise this cell type in vitro and allow for more efficient reprogramming. Granulocytes were isolated from murine bone marrow or human PB and cultured in the presence of a variant of growth factors early or continuously during the reprogramming process. Our preliminary results show that specific growth factors had a significant effect in enhancing the generation of iPSC cells from granulocytes, while other factor combinations had a detrimental effect. In summary, our study has identified haematopoietic cytokine combinations and factors that have a profound effect on the reprogramming of granulocytes. Furthermore, we have devised and optimised a reprogramming protocol for granulocytes. This work can serve as a basis for future work in obtaining large numbers of iPSCs from a clinically relevant cell source.

VALIDATION OF A UNIVERSAL INFORMATICS TOOL FOR KINETIC COLONY CHARACTERIZATION IN TIME-LAPSE MICROSCOPY

Zakary A. Kenyon, **Samuel V. Alworth**, James S.J. Lee
DRVision Technologies LLC, Bellevue, WA, United States

The ability to reprogram somatic cells to an embryonic stem cell-like state has had landmark impact on basic biological research, drug screening, and drug discovery. In order to transition induced pluripotent stem cell (iPSC) technology to the clinic for personalized cell therapy, better reprogramming or direct differentiation strategies are needed to eliminate the viral/genetic footprint. Informatics tools are needed to help scientists develop these new strategies by quantifying images of cells and colonies undergoing reprogramming, expansion or differentiation to extract objective and salient features to reliably predict and/or report assay outcomes. Such tools must be flexible for the universal detection of discriminating cellular kinetic and morphological features for different magnifications, seeding densities, protocols and patient types (i.e. sick, healthy).
We have developed an informatics tool for comprehensive colony characterization in time-lapse sequences. The tool provides flexible colony detection that works for phase contrast and fluorescence, different magnifications, protocols and patient types. The tool can characterize colony formation kinetics at very early time-points. The tool can be easily optimized for different cellular kinetics and morphologies using step-by-step user interface that includes machine learning technologies and teach-by-example interfaces. The tool can quantify many aspects of the single colony kinetics including morphological and fluorescence measures, shape and texture.
We have amassed a large database of images showing fibroblast cells undergoing reprogramming and forming colonies. The database includes several magnifications, three reprogramming protocols, different seeding densities, and disease patients and controls. In the present study, we use this image database with annotated truth to validate the performance of the tool's colony characterization. Many parameters are assessed such as detection, segmentation (i.e. colony border definition) and tracking accuracy. Here we present the tools methodology and validation data which shows good performance on a broad range of usage scenarios.

AUTOMATIC, LABEL-FREE AND REAL-TIME SELECTION OF IPSC COLONIES AT THE TIME OF COLONY EMERGENCE DURING REPROGRAMMING.

Samuel V. Alworth[1], William T. Hendriks[2], Zakary A. Kenyon[1], Samuel Entwisle[2], Thomas Brickler[2], Chieko Nakada[4], Yasujiro Kiyota[4], Laurence Daheron[3], Lee L. Rubin[2], Chad A. Cowan[2], James S. J. Lee[1]
[1]DRVision Technologies LLC, Bellevue, WA, United States, [A]Department of Stem Cell and Regenerative Biology, [B]Harvard Stem Cell Institute, [2]Harvard University, Cambridge, MA, United States, [3]Nikon Corporation, Tokyo, Japan

The ability to reprogram somatic cells to an embryonic stem cell-like state has had landmark impact on basic biological research, drug screening, and drug discovery. However, picking true induced pluripotent stem cell (iPSC) colonies can be unreliable, costly and time consuming. In particular, currently there are no methods to consistently pick fully reprogrammed iPSC colonies at early time points. Early automated selection of iPSC colonies would greatly reduce the cost and labor of iPSC production, facilitating high-throughput application of iPSC technology. In addition, for researchers less familiar with iPSC technology, computer assisted iPSC colony selection would ease implementation of reprogramming in their laboratories.
Previously, using time-lapse, phase contrast microscopy and kinetic image pattern recognition methods applied to retroviral reprogramming of patient fibroblasts, we uncovered a promising, characteristic pattern of colony formation that can be recognized and used to predict the colonies that would become fully reprogrammed. The approach requires three days of imaging (one image every six hours) and quantitative characterization of colony emergence from the time the colonies are first detected. In practical usage, only a few fully reprogrammed iPS colonies are needed to establish new iPSC lines. Thus, we designed our approach to achieve very high specificity while allowing

lower sensitivity. However, in our previous study we were unable to analyze all of the roughly four thousand colonies which were imaged in the 100 mm dish, and could not be sure of the actual false positive rate of our method. In the current study, we improved the automated image analysis and colony prediction methods so that all colonies' formation kinetics could be analyzed and the true performance assessed. To this end, we employed time-lapse microscopy to image retrovirus- and Sendai virus-mediated reprogramming of healthy and disease-specific fibroblasts, using Klf4, Oct3/4, Sox2 and c-Myc. Here we present our new method and results that show iPS selection within 3 to 5 days of colony emergence with high specificity when applied to a large number of colonies. We believe that this imaging method can ultimately be applied to fully automate large-scale production and selection of IPSCs.
Supported in part by grant number 4R44HL106863 from the NHLBI and the Harvard Stem Cell Institute.

CONVERSION OF A RING CHROMOSOME TO UNIPARENTAL DISOMY DURING HUMAN INDUCED PLURIPOTENT STEM CELL GENERATION-IMPLICATIONS FOR DISEASE MODELING AND REPAIR

Marina Bershteyn[1], Yohei Hayashi[2], Edward Hsiao[1], Guillaume Desachy[1], Kathryn Tsang[1], Lauren Weiss[1], Shinya Yamanaka[2], Anthony Wynshaw-Boris[1]

[1]Univ of California, San Francisco, San Francisco, CA, United States, [2]Gladstone Institute of Cardiovascular Disease, San Francisco, CA, United States

Ring chromosomes are found in individuals with mental retardation, seizures and other developmental disorders. Generation of induced pluripotent stem cells (iPSCs) from human fibroblasts with ring chromosomes has not been reported, and it is unclear whether such cytogenetic abnormalities can be modeled with iPSCs. In the course of producing human iPSC models of Miller-Dieker Syndrome (MDS), the most severe form of lissencephaly associated with mental retardation and intractable epilepsy, we tested whether cells from patients with ring chromosomes could undergo reprogramming. MDS is always caused by heterozygous deletions of the most distal region of 17p13.3, with the critical missing region spanning from LIS1 to YWHAE. We used a non-integrating, episomal approach to produce iPSCs from three MDS patients where one of the patients had a ring chromosome 17 with a 17p13.3 deletion (referred to as MDS-1r(17)), while the other two patients (MDS-2 and MDS-3) had similar deletions without a ring chromosome. iPSCs derived from all three MDS patients were functional and exhibited wild type characteristics of self-renewal and differentiation capacity in vitro and in vivo. However, upon differentiation into cortical type neuronal progenitors, MDS-2 and MDS-3 cells exhibited severely impaired proliferation while MDS-1r(17) cells behaved like wild type controls. We investigated the origin of this phenotypic difference and discovered that several independent iPS lines derived from MDS-1r(17) cells had unexpected normal karyotypes without the ring chromosome 17 and surprisingly had wild type levels of LIS1 and YWHAE, in contrast to the 50% reduction of levels of these genes measured in original fibroblasts as well as in iPS lines derived from MDS-2 and MDS-3 patients. SNP arrays revealed two copies of the wild type chromosome 17 in successful iPS clones from MDS-1r(17) fibroblasts, suggesting that compensatory uniparental isodisomy had occurred during the process of reprogramming. Collectively, our results indicate that ring chromosome 17 cannot be modeled in iPSCs as it is incompatible with pluripotent stem cell maintenance. We are in the process of investigating whether this phenomenon is generalizable to other ring chromosomes. Importantly, iPSC reprogramming appears to be a very effective way to correct for this cytogenetic abnormality with important implications for regenerative medicine.

Regeneration Mechanisms

- **ASTROGLIAL ACTIVATION BY ENRICHED ENVIRONMENT AFTER TRANSPLANTATION OF MESENCHYMAL STEM CELLS ENHANCES ANGIOGENESIS AND FUNCTIONAL RECOVERY IN CHRONIC HYPOXIC-ISCHEMIC BRAIN INJURY**

JUNG HWA SEO[1], Ji Hea Yu[2], Ji Yong Lee[2], Yang Hyun Cho[2], Sung-Rae Cho[2]

[A]Graduate Program of Nano Science and Technology, [B]Department & Research Institute of Rehabilitation Medicine, [1]Yonsei University, Seoul, Korea, Republic of

Objective: This study aimed to investigate the effects of angiogenesis coupled with astroglial activation by enriched environment(EE) after transplantation of mesenchymal stem cells(MSCs) on neurobehavioral function in an animal model of chronic hypoxic-ischemic (HI) brain injury.

Methods: HI brain damage was induced in 7-day-old CD-1® mice by unilateral carotid artery ligation and exposure to hypoxia(8% O_2 for 90 min). At 6 weeks of age, the mice were randomly injected with either MSCs(1×10^5 cells) or phosphate buffered saline(PBS) into the striatum and assigned to either EE or standard cages(SC), comprising MSC-EE, MSC-SC, PBS-EE, PBS-SC. Whereas SC controls were housed for the same duration in a standard cage without social interaction, EE mice were housed in a huge cage(86×76×31 cm) containing novel objects and running wheels for voluntary exercise, allowing for social interaction(12-15 mice/cage) for up to 2 months. Rotarod, forelimb-use asymmetry, grip strength, and openfeild tests were performed to evaluate neurobehavioral function. We confirmed the fate of transplanted cells, activated astrocytes and glial scar using immunohistochemistry(IHC). To identify growth factors that are regulated by MSC transplantation and/or EE, neostriata separated from brain, a array-based multiplex ELISA assay was used to determine which of the following 10 cytokines or growth factors were detectable in the neostriata. We also evaluated platelet endothelial cell adhesion molecule-1(PECAM-1) and α-smooth muscle actin(α-SMA) using IHC. **Results:** EE after transplantation of MSCs synergistically improved rotarod latency at constant speed of 48 rpm and at accelerating speed ($p<0.05$). In ladder walking test, the percentage of slips was significantly decreased in MSC-EE($p<0.05$). The grip power relative to preoperative evaluation in the contralateral hemiplegic limb showed significant improvements in MSC-EE($p<0.05$). The density of the transplanted cells in the striatum, were 2.34 fold significantly higher in MSC-EE mice than in MSC-SC mice at 2 weeks after treatment ($p<0.05$). Although grafted cells did not differentiate into a large number of neuronal lineage cells, Tuj-1^+ neurons of grafted cells labeled with BrdU were 2.51 times increased in the MSC-EE group than that in the MSC-SC group at 2 weeks after treatment ($p<0.05$). Furthermore, striatal neurogenesis in MSC-EE mice was significantly increased compared to that in the PBS-SC controls in the damaged striata ($p<0.05$). The level of FGF-2 was significantly elevated in mice with EE after transplantation of MSCs at post-treatment 2 weeks ($p<0.001$) and 8 weeks ($p<0.05$). The number of PECAM-1^+ endothelial cells was significantly higher in mice in EE than those in SC after transplantation of MSCs. Two weeks after EE and MSC transplantation, increased densities of PECAM-1^+ and α-SMA^+ cells were coupled with increased $GFAP^+$ astroglial density in the striatum. However, the levels of the glial scar marker CS-56 did not differ among the groups, demonstrating that the combination of EE and MSCs do not increase the detrimental glial scar formation which inhibits neuroregneration after damage. **Conclusion:** EE and MSC transplantation synergistically improved neurobehavioral functions. The underlying mechanisms of this synergism included enhanced repair processes such as higher engraftment of the transplanted MSCs, increased endogenous angiogenesis and astrocyte activation coupled with upregulation of FGF-2.

W-2242

PRIMING BONE MARROW DERIVED MESENCHYMAL STEM CELLS FOR IMPROVED PARACRINE ACTIVITY

Martin J. Stoddart
AO Research Institute Davos, Davos Platz, Switzerland

Introduction: The immediate response to injury is inflammation. The chemotactic and pro-inflammatory factors secreted by different cells following injury are crucial for triggering tissue regeneration. Specifically, these factors induce homing mechanisms of progenitor cells residing in bone marrow or various organs and the release of secondary signaling molecules involved in healing process and cell differentiation. The importance of these factors is often omitted in bone tissue engineering strategies supporting bone regeneration. We aimed to evaluate the influence of these signals on human bone marrow stromal cells.

Methods: Human bone marrow was obtained from four patients (40-65 years old) undergoing hip replacement. Bone marrow stromal cells (MSC) were isolated through Ficoll gradient followed by adhesion to the plastic. Prolif-

erating cells were treated for 2 hours with interleukin 1 β (IL1β; 10ng/ml), Granulocyte colony stimulating Factor (GCSF; 100ng/ml), Stem Cell Factor (SCF; 100 ng/ml) or Stromal Cell-Derived Factor 1 (SDF-1; 1ug/ml) supplemented to the culture medium (DMEM, 10% Fetal Bovine Serum and 1% antibiotics). Then, cells were incubated with fresh medium for following 72 hours. After that time, total RNA was extracted from cells with TRI reagent followed by on-column clean up and gene expression of 84 cytokines was assessed using RT2 Profiler PCR Array according to the manufacturer protocol (Qiagen). The mRNA expression levels of cytokine mRNA in treated cells were normalized relative to untreated cells (control). For each treatment, cells from at least three donors were included.
Results: As expected the extent of gene regulation was affected by donor variability. Nevertheless, consistent effects of stimulation on several genes important in bone regeneration processes were observed. IL-1β treatment induced the up-regulation of genes involved in angiogenesis (IL-6, IL-8) and osteoclastogenesis (TNSF11), while down-regulating genes regulating chondrogenesis (GDF5). Conversely to IL-1β, GCSF negatively regulated expression of gene involved in osteoclastogenesis (INFA1). Indeed, GCSF stimulated expression of anti-inflammatory genes supporting growth of hematopoetic progenitors (IL-8) and bone formation (IL-10). SCF induced the up-regulation of genes regulating cell differentiation (GDF9) and osteoclast differentiation (TNFSF14). Similarly, SDF-1 positively regulated expression of bone formation factors (IL10, BMP8B). Down-regulation of IL-1β was reported in cells treated with SCF and SDF-1.
Discussion: The results of a 2 hour stimulation of human MSCs with IL-1β, GCSF, SCF and SDF-1 demonstrate the influence of these factors on the expression of genes involved in the bone regeneration process. These results were obtained 72 hours after stimulation, suggesting that a short stimulation, which is feasible within an operating theater, has a longer lasting effect during the vital engraftment period. Grouping of these genes regarding their functional activity allows identifying the relation between the stimulating factor and its action required for callus formation, remodeling, angiogenesis, osteoblast and osteoclast differentiation.
Significance: Integrating inflammatory modulation in bone tissue engineering would provide more powerful strategy to enhance bone regeneration processes.

ACUTE INFLAMMATION THROUGH LEUKOTRIENE SIGNALING PATHWAY TRIGGERS SPECIFIC REGENERATIVE MOLECULAR PROGRAMS OF THE ADULT ZEBRAFISH BRAIN

Caghan Kizil, Nikos Kyritsis, Michael Brand
Center for Regenerative Therapies (CRTD), TU Dresden, Dresden, Germany

The plasticity of the nervous system in zebrafish is unequalled among vertebrates, for instance regarding the regenerative capacity, which manifests poorly in mammals. The disparity between the regenerative capacities of the central nervous system (CNS) of these animals might be stemmed from the prevalence of specific molecular programs that are turned on specifically after the insult. We previously identified that the injury-induced expression of the transcription factor gata3 is one such specific regeneration readout in zebrafish, as gata3 expression is turned on only after an injury in the radial glial stem cells of the adult zebrafish forebrain, but not in mammalian brains. Using morpholino-mediated gene knockdowns, we found that gata3 was required for injury-stimulated proliferation of the stem cells and subsequent regenerative neurogenesis in fish. Yet, the molecular signalling pathways initiating this specific regeneration program with the injury-induced expression of gata3 was unclear. Therefore, we investigated the initial cues that trigger the regeneration response in adult fish brain. By performing transcriptional profiling experiments on the radial glial cells (RGCs) and developing a novel microinjection method in zebrafish brain to manipulate inflammation, we found that acute inflammation is the cue that triggers specific regeneration programs in zebrafish. To test the effects of acute inflammation, we induced sterile inflammation after injecting fluorescent immunogenic molecules without a traumatic lesion. We showed that this injection elicits a proper neuroinflammation similar to that after the lesion based on the expression dynamics of pro-inflammatory cytokines, leukocyte recruitment, and macrophage morphology. We found that sterile acute inflammation is sufficient to enhance the proliferation of RGCs and neurogenesis without causing any cell death. When we immunosuppressed the fish with Dexamethasone after the lesions, RGC proliferation and regenerative neurogenesis ceased, indicating that inflammation is sufficient and necessary for initiating the regenerative programs in the adult fish brain.

We also discovered that the signaling pathways through the lipid Leukotriene C4 (LTC4) and its receptor cysteinyl leukotriene receptor 1 (cystlr1) initiates RGC proliferation and regenerative neurogenesis. When we blocked the activity of cystlr1 upon lesion with the antagonist Pranlukast, RGC proliferation and regenerative neurogenesis reduced significantly. After administration of LTC4 to the unlesioned fish brains, RGC proliferation and neurogenesis increased through induction of gata3 expression. Thus, we identified that unlike the other vertebrates analyzed so far, acute inflammation has an apparent positive role in triggering the activation of the regeneration-specific molecular programs of the adult zebrafish brain involving gata3. We propose that zebrafish can overcome the detrimental effects of inflammation via special molecular programs linking the non-physiological conditions of traumas to re-development of the lost tissues in part by activating gata3. Our results provide an important fulcrum to the hypothesis that special regenerative programs that enable tissue replenishment might exist in regenerating organisms and understanding such programs would endow us to harness those mechanisms in efforts for clinical regenerative therapies for neurodegenerative disorders or acute injuries in human CNS.

W-2244

WNT SIGNALING IS REQUIRED FOR KIDNEY REGENERATION FROM ADULT ZEBRAFISH NEPHRON PROGENITOR CELLS

Caramai N. Kamei, Yan Liu, Iain A. Drummond
Medicine, Massachusetts General Hospital, Charlestown, MA, United States

Background:
In contrast to mammalian kidney regeneration, zebrafish can not only repair existing nephrons but are also capable of de novo generation of new nephrons from adult organ progenitor cells. Activation of both repair mechanisms is likely to be signaled by positive and negative growth regulators that ultimately restore normal kidney function. We report here that Wnt signaling plays a role in adult zebrafish kidney regeneration.
Methods:
In situ hybridization as well as a transgenic reporter line expressing gfp in regenerating lhx1a-positive nephron progenitors was used to visualize regeneration in response to acute gentamicin injury. Wnt signaling was perturbed using the chemical activator BIO and the inhibitor XAV939.
Results:
Both individual lhx1a-positive adult kidney progenitor cells and differentiating cell condensates are specifically marked by expression of the Wnt receptor frizzled9b (fzd9b). Active Wnt signaling was detected in differentiating nephron progenitors by expression of the canonical Wnt target lef1. Acute injury to the adult zebrafish kidney by gentamicin injection significantly expanded the population of fzd9b-positive nephron progenitors. Pharmacological blockade of Wnt signaling reduced progenitor cell expansion after injury while activation of Wnt signaling was sufficient to expand fzd9b/lhx1a-positive progenitors in the absence of injury.
Conclusions:
Our results demonstrate a role for Wnt signaling in adult zebrafish kidney regeneration and identify fzd9b as a new marker of adult kidney progenitor cells. Our results open new avenues to investigate the developmental origins and regenerative potential of nephrogenic stem cells.

ANALYSIS BY LINEAGE TRACING OF ENDOTHELIAL REGENERATION IN MICE FOLLOWING LUNG VASCULAR INJURY INDUCED BY ENDOTOXIN

Min Zhang, Yanmin Zhang, Peter Toth, Xiaojia Huang, Jalees Rehman, Asrar B. Malik
Univ of Illinois at Chicago, Chicago, IL, United States

Acute lung injury (ALI) secondary to lung vascular endothelial injury is a common cause of edema formation and respiratory failure in critically ill patients. Studies have shown that in animal models and patients there is a potential for regeneration of the injured and apoptotic vascular endothelium. However, the primary source of endotheli-

al cells for vascular repair and regeneration remains unclear, and could be driven by proliferation of residual endothelial cells or by the differentiation of stem or progenitor cells into endothelial cells capable of restoring vascular integrity. To answer this question, we performed a Cre/loxP-based lineage-tracing study using tamoxifen inducible Cre-transgenic mice driven by the 5' endothelial enhancer of the stem cell leukemia (SCL) locus. The endothelial-SCL-Cre-ERTAM mouse was bred to a double-fluorescent mT/mG reporter mouse which expressed membrane-targeted tandem dimer Tomato (mT) prior to Cre-mediated excision and membrane-targeted green fluorescent protein (mG) after excision. The vascular endothelial cells were thus GFP+ and non-endothelial cells were Tomato-Red+. We found that the GFP+ endothelial cells were the primary source of endothelial regeneration that occurred 72 hr following lung vascular injury induced by sub-lethal endotoxin lipopolysaccharide (LPS). This was evident by a time-dependent decrease in the number of GFP+ endothelial cells relative to Red+ cells occurring at 12 hr followed by normalization of the ratio at 72 hr (the repair phase). Also, the GFP+ endothelial cells in contrast to the Red+ cells showed 2- to 3- fold increase in proliferation and expression of cyclin genes cyclinF and cyclinA2. These results support the hypothesis that restoration of lung vascular endothelial integrity following LPS is the result of proliferation of pre-existing endothelial cells as opposed to the differentiation of non-endothelial stem or progenitor cells.

A NEW APPROACH TO LYMPHATIC DIFFERENTIATION FROM HUMAN PODOPLANIN-POSITIVE MYELOID CELLS FOR ENHANCING LYMPHANGIOGENESIS

Ji-Yeon Yun, Jin Hur, Jin-A Kang, Jae-Il Choi, Young-Eun Choi, Ju-Young Kim, Ji-Hoon Hong, Chang-Hwan Yoon, Sang Eun Lee, Hyun-Jai Cho, Young-Bae Park, Hyo-Soo Kim
Seoul National Univ Hospital, Seoul, Korea, Republic of

Lymphatic vessels are a critical part of the body's immune system. They have a very important role in the pathogenesis of several diseases, such as lymphedema and various inflammatory conditions like attenuated wound healing in diabetes. In order to treat human lymphatic vessel diseases, regeneration of new lymph vessels has attracted academic attention for recent years.
Previous study suggests lymphangiogenesis can occur by mouse
monocyte aggregates transdifferentiating into lymphatic endothelial cells. Emerging studies have also suggested that murine podoplanin-positive myeloid cells are crucially involved in lymphangiogenesis. However, in human conditions, we do not know whether podoplanin-positive myeloid cells could be obtained from peripheral blood and how valuable they are therapeutically. With this study, we investigated the lymphatic differentiation of myeloid cells obtained from human peripheral blood by using aggregate culture condition. Upon closer examination of these human peripheral blood monocyte aggregates, we discovered interesting evidence that the human myeloid cells constituting these aggregates gradually increased the expression of lymphatic endothelial cell markers such as podoplanin and VEGFR-3 during aggregate culture. In particular, monocyte cells sorted for podoplanin markers showed more lymphatic endothelial cell markers such as VEGFR-3, Prox-1, SOX-18 than podoplanin negative cells. The podoplanin-positive cells had a leaf-shape like lymphatic-endothelial cells (LECs) during myeloid aggregates culture and they were also able to participate in LECs in vitro Matrigel. We also confirmed the indirect impact on lymphangiogenesis as well as the direct lymphatic differentiation
ability of podoplanin-positive myeloid cells. The supernatant of them was able to enhance the migration, viability and proliferation of LECs. Local injection of podoplanin-positive cells in monocyte aggregates significantly increased lymphatic neovascularization and facilitated wound healing in the full-thickness skin wounds of mice.
We demonstrated a new approach to induce lymphatic differentiation from podoplanin-positive cells in 3D monocyte aggregate culture system, which would be a promising novel strategy of cell therapy to treat human lymphatic vessel disease.

ENHANCED LIGAMENT HEALING USING MESENCHYMAL STEM CELLS

Erin Saether, Connie Chamberlain, Jackie Kondratko, Ellen Leiferman, Stacey Brickson, Wan Ju Li, Ray Vanderby

Orthopedics, University of Wisconsin - Madison, Madison, WI, United States

Objective: Enhance early stage healing in rat medial collateral ligaments (MCLs) using mesenchymal stem cells (MSCs). Specifically, learn how MSCs modulate the inflammatory and immune response upon injury to the MCL.
Methods: A total of 24 rats underwent bilateral MCL transection. Day 5 and day 14 healing was examined comparing two cell doses ($1x10^6$ MSCs and $4x10^6$ MSCs). At the time of surgery, fluorescently-labeled rat MSCs (passage 8-10) were injected into the right transected MCL, while the left MCL served as the control for normal healing. MCLs were collected at the different healing time points and processed with immunohistochemistry (n=12). Type 1 Macrophages (M1), type 2 Macrophages (M2), endothelial cells, proliferating cells, total cells, MSCs, procollagen 1, Collagen 3 and T cells were quantified spatially within the healing ligaments. H+E staining was performed to analyze tissue morphology and the size of the healing region at different time points. Twelve rats underwent MSC injections for mechanical testing.
Results: MSCs were detected solely in the healing region and healing region edges at Day 5 and Day 14 in both dose groups using fluorescence microscopy.
At day 5 healing, the higher dose of cells demonstrated significant changes throughout the ligament with M2's and Procollagen 1. There were more M2's (p=.05) in the distal and proximal healing regions of the normal healing ligament compared to the MSC injection group. Procollagen 1, the precursor to Collagen 1, was increased (p=.05) throughout the MCL that received MSCs.
There were significant changes in both the low dose and high dose groups at day 14. Fewer M1's were found in the ends (p=.01) and throughout the MCL (p=.04) in the low dose group. M2's were decreased in the ends (p=.04), but only in the ligaments that received the higher dose of MSCs.
At day 14, the low dose group had fewer proliferating cells (p=.003) in the healing region compared to the control, whereas in the high dose group there were fewer proliferating cells (p=.05) in the ligament ends.
There were fewer endothelial cells in the ends (p=.03) of the low dose MSC group at day 14, along with fewer lumen in the ends (p=.04) and MCL (p=.002) as a whole.
No significant differences were detected in T cells or Collagen 3.
H+E staining showed a decrease in the length of the healing region in the low dose MSC group. The average length of the healing region in the MSC group was 1.4 mm compared to 2.5 mm (p=.003) in the control ligaments.
By calculating percentage of the healing region size, the low dose group at day14 reached a level of significance (p=.04) with the MSC group's average size representing 8.4% of the ligament and the control 10.4%.
The mechanical results correlated with the healing region size data. The low dose MSC injection group demonstrated increased strength with an average failure load of 26.41N compared to 20.88N in the control group (p=.03). These ligaments also exhibited increased stiffness with an average of 12.24 N/mm compared to 10.01 N/mm (p=.01) in the control ligaments.
Conclusion: MSCs demonstrated a positive healing effect when applied at an appropriate dose shown by a smaller wound size and improved mechanical properties at day 14. Interestingly, the smaller dose of 1 million cells proved to be more successful than the larger dose of 4 million cells. MSCs also affected the cellular response in regard to macrophage phenotype, endothelialization, and proliferating cells in healing MCLs.

W-2248

LOW-FREQUENCY PULSED ELECTRICAL FIELD WITH CERTAIN PARAMETERS INDUCES ERYTHROPOIETIN PRODUCTION, ACTIVATES THE POOL OF MESENCHYMAL STEM CELLS AND ENHANCES REGENERATIVE PROCESSES IN LABORATORY ANIMALS

Mikhail Konoplyannikov[1], Anatoly Konoplyannikov[2]
[1]Federal Research Clinical Center, Moscow, Russian Federation, [2]Medical Radiological Research Center, Obninsk, Russian Federation

Mesenchymal stem cells (MSC) are currently considered as a key component of physiological and "emergency" organism regeneration. We have shown that short-duration action of low-frequency pulsed electrical field with certain parameters onto laboratory animals induces enhanced erythropoietin production, accompanied by increase

in the blood level of reticulocytes and by the activation of the pool of bone marrow MSC. This results in the accelerated healing of wounds and burns, diminishment of radiation damage and other manifestations of enhanced regenerative activity of many tissues. Besides, we have shown that once-per-week treatment of linear mice with low-frequency pulsed electrical field, started at the age of 3 months, statistically significantly extends the animals' life expectancy. It is possible that the observed effects are based on the stimulation of the regenerative potential of MSC due to the erythropoietin action on the specific receptors of the cells. This finding opens new directions for the development of medical technologies of regenerative medicine.

W-2251

VASCULAR ENDOTHELIAL GROWTH FACTOR ENHANCES HUMAN FETAL MESENCHYMAL STEM CELL MIGRATION AND ADHESION

Joan X. Yang, Florentina M. Widodo, Mahesh A. Choolani, Koon Gee Neoh, Jerry KY Chan, Yaw Chyn Lim
National Univ of Singapore, Singapore, Singapore

During injury, chemokines and growth factors (GF) act in concert to recruit different cells types to facilitate repair. Factors such as vascular endothelial growth factor (VEGF) which are produced by endothelial cells (EC) in hypoxic conditions, platelet-derived growth factor (PDGF) which are produced mainly by platelets, and CXCL12/stromal cell-derived factor-1 (SDF-1) are found at high concentrations at inflammatory or injury sites.
Mesenchymal stem cells (MSC) have great potential for therapeutic applications in regenerative medicine. However, despite the numerous reports on MSC migration and homing, their molecular mechanisms have yet to be fully elucidated and understood. Current literature have depicted the importance of the CXCR4-SDF-1 axis in MSC homing and migration. We thus hypothesize that VEGF can modulate the response of human fetal MSC (hfMSC) to SDF-1 and their adhesive capacity at the injury site.
Firstly, we examined hfMSC migration in response to different GF known to be present at the injury site. Except for PDGF (1.30 fold increase against control, $p<0.05$), the other GF did not promote significant migration of hfMSC. We also mimicked the physiological conditions by stressing human umbilical vein EC (HUVEC) under nutrient-deprived conditions and used the conditioned medium (CM) to stimulate hfMSC overnight. We found that CXCR4 expression on CM-treated hfMSC was increased by 1.14 fold ($p<0.05$) compared to untreated controls.
Microparticles (MP) have recently be discovered as a biomarker for various diseases. Endothelial MP (EMP) contain proteins and nucleic acid materials derived from EC. We found that MP derived from stressed HUVEC also augmented CXCR4 expression on hfMSC compared to untreated controls.
As VEGF is a major angiogenic GF secreted during wound healing and possibly also present in the stressed HUVEC CM, we investigated the effects of VEGF on hfMSC migration towards SDF-1. Varying durations of VEGF treatment resulted in differing responses to SDF-1. While 15-minutes treatment did not elicit significantly migration, VEGF treatment for 4 hours resulted in a 1.54 fold increase ($p<0.05$) in hfMSC migration towards 5ng/mL SDF-1 compared to spontaneous migration in the absence of SDF-1. In comparison, untreated cells only showed a 1.12 fold increase in migration in response to SDF-1. 24 hours VEGF treatment also resulted in a significant increase in hfMSC migration, albeit with a smaller magnitude. The treatment, however, did not affect the number of CXCR4 expressing cells nor change the expression of CXCR4 on the cells per se. This suggests that VEGF influence hfMSC response to SDF-1 by modulating the affinity of CXCR4.
Next, we investigated the effect of VEGF treatment on hfMSC adhesion to fibronectin (FN) and vascular cell adhesion molecule-1 (VCAM-1). VEGF treatment augmented hfMSC adhesion to FN and VCAM-1 as compared to bovine serum albumin-coated surface.
Adhesion to FN and VCAM-1 was also dependent on the duration of treatment, with shorter treatments leading to more significant increase in adhesion. Additionally, hfMSC consistently adheres better to FN than to VCAM-1.
Our data supports our hypothesis that recruitment of hfMSC can be modulated by factors, such as VEGF and SDF-1, found at the injury site. hfMSC treated with VEGF *in vitro* augments their migratory response to SDF-1 and binds better to VCAM-1 and FN, thus suggesting that VEGF may be used to augment hfMSC engraftment in tissues.

TRANSPLANTATION OF MESENCHYMAL STEM CELLS PROMOTES TISSUE REGENERATION IN A GLAUCOMA MODEL THROUGH LASER-INDUCED PARACRINE FACTOR SECRETION AND PROGENITOR CELL RECRUITMENT

Renaud Manuguerra, Patrick Boulos, Ahmed Ammar, François Leblond, Gorazd Krosl, Vincent Pichette, Mark Lesk, Denis-Claude Roy
University of Montreal / Maisonneuve-Rosemont Research Center, Montreal, QC, Canada

Among bone marrow cells, hematopoietic and mesenchymal components can contribute to repair damaged organs. Such cells are usually used in acute diseases but few options are available for the treatment of chronic disorders. In the present study, we have used a laser-induced model of open angle glaucoma (OAG) to evaluate the potential of bone marrow cell populations and the mechanisms involved in tissue repair. In addition, we investigated laser-induced tissue remodeling as a method of targeting effector cells into damaged tissues. We demonstrate that among bone marrow cells, mesenchymal stem cells (MSC) induce trabecular meshwork (TM) regeneration. MSC injection into the ocular anterior chamber lead to far more efficient decrease in intraocular pressure (IOP)($P<0.001$) and healing than hematopoietic cells. This robust effect was attributable to paracrine factors from stressed MSC, as injection of conditioned medium from MSC exposed to low but not to normal oxygen levels resulted in an immediate decrease in IOP. Moreover, MSC and their secreted factors induced reactivation of a progenitor cell pool found in the ciliary body and increased cellular proliferation. Proliferating cells were observed within the chamber angle for at least 1 month. Laser-induced remodeling was able to target MSC to damaged areas with ensuing specific increases in ocular progenitor cells. Thus, our results identify MSC and their secretum as crucial mediators of tissue repair in OAG through reactivation of local neural progenitors. In addition, laser treatment could represent an appealing strategy to promote MSC-mediated progenitor cell recruitment and tissue repair in chronic diseases.

MESENCHYMAL STROMAL CELL (MSC) THERAPY RESTORES RADIATION-INDUCED DYSFUNCTION IN THE NEURAL CONTROL OF COLONIC CIRCULAR MUSCLE CONTRACTIBILITY THROUGH ANTIOXIDANT EFFECTS

Christelle DURAND, Noelle MATHIEU, Christelle DEMARQUAY, Raphaelle BESSOUT, Marc BENDERITTER, **Alexandra SEMONT**
Institut of Radiation protection and Nuclear safety, Fontenay aux Roses, France

Objective: Patients who undergo pelvic or abdominal radiotherapy may develop high incidence of undesirable acute and/or chronic gastrointestinal complications resulting from radiation-induced damages around the tumour. The growing number of cases declared each year and the specific complex symptoms have lead some specialists to talk of a new disease termed “pelvic-radiation disease”. The lack of curative treatment and the potential severity of the disorder highlight the importance of novel and effective therapeutic strategies. In this study, we tested the therapeutic benefit of MSC treatment on radiation-induced dysfunction of colonic circular muscle contractibility (CCMC).
Methods: Rats SD were subjected to a 27 Gy colorectal irradiation. Bone marrow derived MSC (5.106) were intravenously administered three weeks (curative effects) after radiation exposure. Therapeutic effects of MSC were analysed 4 weeks after irradiation. We performed colonic muscle histological (HES) analysis and ex vivo quantification of CCMC in response to escalating doses of Carbachol (non-selective agonist of choline acetyl (Ach), doses: 10-8M to 5.10-4M) with or without inhibition of neural transmission by tetrodotoxin (TTX). Immunostaining of nitrergic neurons (nNO) using neuronal nitric oxyde synthase antibody and cholinergic neurons (nAch) using choline acetyltransferase antibody, were also investigated in myenteric nervous plexus.
Results: Four weeks after irradiation, even if no histological alterations of the circular muscle was observed, we reported a significantly CCMC reduction. Radiation-induced CCMC dysfunction was restored after MSC treatment. Therapeutic effect of MSC is dependent of their ability to restore a normal neutrally induced muscle activity by the re-establishement of the balance between myenteric inhibitory (nNO) and excitatory (nAch) control of CCMC. Indeed, MSC treatment decreased the proportion of myenteric nNO and its activity and increased the proportion of myenteric nAch. This therapeutic effect on enteric nervous system is partially dependent of MSC abilities to reduce oxidative stress via the modulation of glutathione (GSH). Moreover, reduction of CCMC after irradiation was

minimised by the inhibition of lymphocyte T (LT) using a treatment with an anti-CD3. We reported in this study that MSC treatment reduced the activation of LT, mechanism that also might be implicated in MSC therapeutic efficacy on radiation-induced CCMC alterations.
Conclusion: This work constitutes new insights that are arguing in favour of the use of MSC for compassionate applications in order to try to reduce irreversible, pelvic radiotherapy-induced gastrointestinal complications.

W-2254

HEALING A BROKEN HEART; STEM CELL THERAPY FOR DILATED CARDIOMYOAPTHY IN DUCHENNE MUSCULAR DYSTROPHY

Suzanne Berry, Ju Lan Chun, Bob O'Brien, Minho Song
University of Illinois, Champaign, IL, United States

Duchenne muscular dystrophy (DMD) is the most common form of muscular dystrophy, resulting from mutations in the dystrophin gene. Nearly 100% of Duchenne muscular dystrophy (DMD) patients develop dilated cardiomyopathy (DCM) as well severe, progressive pathology in skeletal muscle, and 20-40% succumb to cardiomyopathy. Current methods of management for DCM delay or alleviate decline in cardiac function and remodeling, but will not be curative because they do not restore dystrophin protein or replace damaged cardiac muscle cells. Stem cell therapy offers a mechanism to simultaneously replace damaged cardiomyocytes and restore dystrophin. However, few studies have been conducted to determine whether stem cells will perform these functions in dystrophin-deficient heart and none have previously reported functional benefit.
We have discovered that aorta-derived mesoangioblast stem cells (ADM), with a functional copy of the dystrophin gene, prevent ventricular dilation and a decline in cardiac function in murine models for DMD when transplanted in the heart prior to development of pathology. A number of changes were observed that may account for the prevention of cardiomyopathy. ADM transplantation resulted in the presence of low numbers of dystrophin-positive cardiomyocytes, an increase in vasculature and division of resident nestin+ cardiac stem cells, and the appearance of nestin+ cardiomyocytes of host origin, in dystrophin-deficient heart. It is not yet clear which of these changes is necessary for the observed benefit from ADM. Although angiogenesis in cardiac muscle has been reported to improve heart function following ischemic damage in multiple preclinical and clinical studies, it has not been tested for benefit in dystrophic heart. Dystrophin-deficient cardiomyopathy is not ischemic in origin. However, because an increase in vasculature in our study correlated with functional benefit, an increase in blood flow may also improve cardiac function in DMD. Preliminary studies indicate that the increase in vasculature with ADM transplantation is in the form of vasculogenesis rather than angiogenesis. These data may be useful for developing mechanisms to increase blood flow in dystrophic heart and also suggest that ischemia may be present in dystrophin-deficient heart.
The function of nestin+ cardiac stem cells in normal heart is not known. Our data suggest that resident nestin+ stem cells may be activated to generate new cardiomyocytes in the heart. Consistent with this possibility, a lineage tracing study by another group reported that a subset of nestin+ stem cells in normal adult heart differentiate into cardiomyocytes. We have more recently detected large clusters of nestin+ cardiomyocytes in the heart of 3 different murine models for DMD at the end stages of disease, when extensive pathology is present, even in the absence of ADM injection. Similarly, nestin+ striated cells have also been reported by another research group in the heart of human patients at the end stages of heart failure. Together with this report, our observations of nestin+ striated cells in the dystrophic heart suggest that endogenous stem or progenitor cells may be activated prior to damage, or respond to severe damage in the heart, to generate new cardiomyocytes. We are currently evaluating whether changes in the vasculature and/or activation of nestin+ stem cells may be exploited independently of ADM transplantation to prevent or delay cardiomyopathy in dystrophic heart.

W-2255

TRANSPLANTATION OF PLURIPOTENT STEM CELL DERIVED HUMAN NEURAL PRECURSOR CELLS INTO THE MHV MODEL OF MULTIPLE SCLEROSIS LEADS TO STABLE CLINICAL RECOVERY

Ronald L. Coleman[1], Lu Chen[2], Ronika Leang[2], Suzanne E. Peterson[1], Tom E. Lane[2], Jeanne F. Loring[1]

[1]Department of Chemical Physiology, The Scripps Research Institute, La Jolla, CA, United States, [2]Department of Molecular Biology and Biochemistry, University Of California, Irvine, CA, United States

Multiple Sclerosis (MS) is an immune-mediated chronic disease of the central nervous system (CNS) that is characterized by demyelination. Using mice infected with a neurotropic JHM variant of mouse hepatitis virus (JHMV) as a model of MS, we injected human neural precursor cells (hNPCs) derived from human pluripotent stem cells (hPSCs) to explore treatment options for the disease. Two weeks after JHMV infection, hNPCs were transplanted into the spinal cords of mice that exhibited clinical symptoms of the disease. The mice were then scored daily on a clinical diagnostic scale. Mice that were treated with the hNPCs showed significant improvement over mice that received a control treatment as well as mice that had transplantation of human dermal fibroblasts. Additional experiments showed continuing improvement for 3 months post transplantation and sustained recovery for 6 months (the longest duration of the experiment). Some of the mice were sacrificed at 21 days post-transplantation, and their spinal cords were analyzed. Spinal cords of mice treated with hNPCs showed remyelination and decreased macrophage and T-cell infiltration. The decrease in inflammatory cells was correlated with the increase in remyelination.

In order to determine the fate of the transplanted hNPCs, WA09 hES cells were transduced with lentivirus containing an integrating vector with the P. pyralis luciferase gene driven by the cytomegalovirus (CMV) promoter. These cells retained expression of the reporter after differentiation to hNPCs. Mice transplanted with the labeled NPCs were injected with luciferin and imaged daily. No luciferase-expressing hNPCs were detected after day 7 post-transplantation.

To further examine the mechanism of hNPC-mediated recovery, we performed whole genome expression profiling studies on the cells. We identified genes that were differentially expressed in hNPCs relative to fibroblasts and undifferentiated cells. Because of the short survival time of the transplanted cells, we focused on differentially expressed genes coding for secreted proteins. We are assessing these candidates for their potential roles in immunomodulation or oligodendrocyte maturation. The expression of these genes is being verified through quantitative real-time PCR (qRTPCR) and western blot analysis. Genes verified in this manner will be further validated in in vitro and in vivo systems.

Our results show that hNPC transplantation can mediate recovery in a mouse model of MS. Although the hNPCs are rapidly cleared, the mice showed a robust and stable recovery that included remyelination, decrease of inflammation and a lessening of pathological symptoms. Long term, we hope to develop novel stem cell-based therapies to help recovery of MS patients.

CO-EXISTENCE OF QUIESCENT AND ACTIVE RADIAL NEURAL STEM CELL POPULATIONS IN THE ADULT HIPPOCAMPUS

Michael A. Bonaguidi[1], Ryan Stadel[2], Yoon Namgung[3], Steven Park[3], Teresa Krieger[6], Jung Jin Oh[3], Guo-li Ming[4], Benjamin D. Simons[6], Hongjun Song[5]

[A]ICE / Neurology, [B]ICE / Human Genetics, [C]ICE, [D]ICE / Neurology / Dept. of Neuroscience, [E]ICE / Neurology / Dept. of Neuroscience / Human Genetics, [1]Johns Hopkins University SOM, Baltimore, MD, United States, [2]Cavendish Laboratory, Dept of Physics/Gurdon Institute, University of Cambridge, Cambridge, United Kingdom

New neurons are continuously generated in the hippocampus throughout life and contribute to specific brain functions. One fundamental question is whether new neurons arise from precursors with characteristics of stem cells or progenitors and whether these precursor properties are uniform. Within the subgranular zone of the adult dentate gyrus, our previous clonal lineage tracing using Nestin::CreERT2 (#) showed that radial glia-like precursors (Nestin#-RGLs) act as quiescent neural stem cells possessing long-term self-renewal and multipotential differentiation capacity. Multiple evidence from population analyses suggests additional cell sources of constitutive neurogenesis in the adult hippocampus. Here, we performed in vivo single-cell lineage-tracing of two RGL subpopulations using the Gli1::CreERT2(#) and Mash1::CreERT2(#) systems. Gli1#-RGLs are initially quiescent but rapidly activate upon label-

ing. These RGLs return to quiescence after either symmetric or asymmetric (neurogenic or astrogliogenic) division. Computational modeling indicates that Gli1#-RGL decisions occur at similar frequencies as Nestin#-RGLs. In contrast, Mash1#-RGLs are already active upon labeling, but primarily undergo neurogenic, asymmetric divisions and undergo long-term self-renewal. Computational modeling suggests that Mash1#-RGLs are biased toward neurogenic self-renewal and represent a distinct unipotential active neural stem cell population. Our study reveals novel insight into the heterogeneity of neural stem cells in the adult brain and supports the co-existence of both quiescent and active neural stem cells in the same somatic compartment where multipotential stem cells cycle between quiescence and activation states, and another more active unipotential stem cell primarily generates neurons.

W-2257

TARGETED ACTIVATION OF PRIMITIVE NEURAL STEM CELLS IN THE MOUSE BRAIN

Rachel Leeder, Brian DeVeale, Cindi M. Morshead, Derek van der Kooy
University of Toronto, Toronto, ON, Canada

Primitive neural stem cells (pNSCs) first appear at embryonic day 5.5 and persist into the adult mouse brain. Primitive NSCs comprise a rare population of GFAP-negative cells that give rise to LIF-dependent neurospheres in culture. They can be passaged in vitro to self-renew or give rise to definitive (d)NSCs, which are GFAP-positive and EGF- and FGF-dependent. Primitive NSCs express low levels of Oct4 and contribute to chimeric blastocysts, both markers of pluripotency not exhibited by dNSCs. We confirmed that pNSCs derived from the pup and adult brain self-renew at the same frequency. We previously observed that pNSCs from the adult brain give rise to equal proportions of neurons, oligodendrocytes and astrocytes following differentiation. Here, we report that pup-derived pNSCs give rise to fewer neurons and more oligodendrocytes than their adult counterparts. This difference in differentiation profiles may reflect the contribution of pNSCs to the wave of oligogenesis that occurs soon after birth. Finally, qPCR to compare pup and adult pNSCs suggests similar gene expression in the two populations. Together, this suggests that pup-derived pNSCs are more abundant, but similar to the adult population, and thus are a valuable population to investigate strategies to isolate and manipulate the pNSC population to better understand its role in the neural lineage. A previous mass spectrometry based screen of in vitro ESC-derived primitive neurospheres identified cell surface markers selectively upregulated in pNSCs compared to ESCs and dNSCs. We are testing these cell surface markers to identify factors that selectively affect the ability of pNSCs to form clonal LIF neurospheres, independent from dNSCs. Specifically, Gleevec, a c-kit pathway inhibitor, significantly increased pNSC neurosphere formation while attenuating dNSC neurosphere formation. Similarly, an ErbB2 inhibitor also selectively increased primitive neurospheres while depleting definitive neurospheres. We confirmed the selective effects of Gleevec using a c-kit siRNA, and the effects of the ErbB2 inhibitor with an ErbB2 siRNA. Next, we infused Gleevec and ErbB2 inhibitor into the lateral ventricle of adult CD1 mice to test the effectiveness in vivo. We observed similar increases in pNSCs following a 3-day infusion and primary dissection to perform a neurosphere assay. Importantly these in vitro to in vivo experiments suggest that markers and inhibitors identified in the pup population can be generalized to adult pNSCs. As well, Gleevec and ErbB2 inhibitors represent two methods of manipulating pNSCs. These methods will enable selective targeting and manipulation of pNSCs to better understand their function in the adult mouse brain.

W-2258

TRANSPLANTED HUMAN NEURAL STEM CELLS RAPIDLY AMELIORATE EARLY DISEASE SYMPTOMS IN A MOUSE MODEL OF CEREBRAL ISCHEMIA

Lei Huang[1], **Jean-Pyo Lee**[2]
[A]Center for stem cell research and regeneration, [1]Tulane Univ Sch of Medicine, New Orleans, LA, United States

Reciprocal interactions occur between neural stem cells (NSCs) and injured host cells. Cerebral ischemia, a common cause of neurologic disability in adults and children, results in loss of cerebral parenchyma and its associated cells and connections. Previously, we exploited cytokines (proinflammatory stem cell factors, which reportedly facilit-

ate stem cell migration into brain injury sites) by demonstrating improved stem cell migration in mid-symptomatic Sandhoff-diseased mice (exhibit lethal gangliosidosis).
Here we assessed the impact of human NSCs in a mouse stroke model by asking the following: Would proinflammatory cytokines promote migration of engrafted NSCs to pathologic sites caused by middle cerebral artery occlusion (MCAO)? Would stem cell-derived factors suppressed proinflammatory genes that function in the breakdown of the blood brain barrier (BBB) and blood cell extravasation into the brain caused by MCAO? We induced MCAO in C57BL6 mice, followed by a 60-minute reperfusion to induce ischemia. NSCs were transplanted intracranially after 24 hours, during the period in which proinflammatory cytokines are upregulated. At 24 hours posttransplantation, transplanted cells indeed migrated extensively and homed to pathologic sites. Cytokines, including TNF-α, IL-6, IL-1β, were downregulated (RT-PCR analysis); Iba1+ active inflammatory cells were significantly decreased (immunostaining); claudin 5, a tight junction protein in blood vessels, was upregulated (Western analysis), suggesting decreased BBB permeability; and infarct volume was decreased (cresyl violet staining). Further, mouse physical behaviors remarkably improved (e.g., rotarod and beam walk tests).
Overall, transplanted NSCs acted swiftly to reduce inflammation and stabilize the BBB following stroke in mice. Thus, our data indicate the potential benefits of NSC transplantation as a therapy following stroke.

W-2261

REJUVENATION OF NEUROGENESIS AND ANGIOGENESIS IN THE AGED BRAIN

Lida Katsimpardi[1], Nadia K. Litterman[1], Pamela A. Schein[1], Christine M. Miller[2], Amy J. Wagers[2], Lee L. Rubin[1]
[1]Stem Cell and Regenerative Biology, Harvard University and Harvard Stem Cell Institute, Cambridge, MA, United States, [2]Stem Cell and Regenerative Biology, Harvard University and Harvard Stem Cell Institute, Cambridge, MA, Howard Hughes Medical Institute and Joslin Diabetes Center, Boston, MA, United States

In the adult mammalian brain, neural stem cells generate new neurons in two discrete areas, the hippocampus and the subventricular zone (SVZ), throughout the lifespan of the animal. Ageing reduces neural stem cell numbers, as well as their self-renewing potential, leading to an overall decline in neurogenesis. However, age-related decline in neurogenesis can be positively regulated by manipulations such as stress and physical exercise, providing evidence that extrinsic factors can delay or even reverse this part of the ageing process. Here we present a study of systemic regulation of SVZ neurogenesis. Using the paradigm of heterochronic parabiosis, where an old and a young mouse are surgically connected so that they share the same circulatory system, we show that the age-related decline of neural stem cell activity in the old mouse is counteracted by systemic factors present in young blood. The pool of neural stem/progenitor cells in the SVZ in the aged brain is increased after exposure to a young circulatory system, leading to an enhancement of olfactory bulb neurogenesis. Importantly, the increase in neurogenesis is associated with a marked increase in the volume of capillaries in the aged SVZ, as well as in other regions of the brain. Unraveling the mechanisms of this phenomenon could have beneficial implications in treating neurodegenerative as well as neurovascular diseases.

W-2262

SUBSTANCE-P MODULATES ENDOTHELIAL PERMEABILITY AND AUGMENTS TRANSENDOTHELIAL MIGRATION OF MESENCHYMAL STEM CELL

Suna Kim, Hyun Sook Hong, Eunkyung Chung, Youngsook Son
Genetic engineering, Kyung Hee University, Yong In, Korea, Republic of

Endothelial cell layer in blood vessel plays an important regulatory role in infiltration of circulating molecules and immune cells to underlying tissue. Substance-P (SP), a member of neuropeptides, is known to mediate pain perception and regulate inflammation. Another point we noticed about SP is a new role as a wound messenger to mobilize mesenchymal stem cells (MSC) from bone marrow that promotes healing mechanisms in various injury models. This study was aimed to reveal early event of the MSC homing mechanism under the influence of SP which might be similar to the SP-treated injured condition. We explored SP's effect on endothelial cells as well as on the

trafficking of MSCs through endothelial monolayer *in vitro*. For measuring endothelial permeability, flux of 40 kDa FITC-dextran from lumen side to basal side was determined in the presence or absence of SP or TNF-α in the lumen side. SP transiently increased FITC-dextran flux, peaked at 5 min and decreased to basal level at 10 min after SP treatment. Based on immunofluorescence staining, SP treatment stimulated the formation of discontinuous and jagged adherens junctions in a multiple interconnected finger-like structure transiently, which was featured by changes in distribution of VE-cadherin and actin cytoskeleton. This SP-mediated gap opening was mostly resealed at 30 min after the SP treatment. In contrast, TNF-α stimulated vascular permeability for much longer duration and completed opening of intercellular junction, which seemed to be mediated by p38 MAPK activation and followed by subsequent induction of VCAM-1 and ICAM-1. Then, we explored whether SP treatment affects trafficking of MSCs. SP stimulated the invasion of MSCs from the lumen side to the basal side through transendothelial migration in 3-D culture system *in vitro*. Collectively, SP directly modulates vascular permeability and homing mechanisms of MSCs through transient regulation of intercellular adherens junction. This study provides the insight into early event of SP-stimulated MSCs homing to the injured tissue, which may be a critical step to explain SP-stimulated tissue repair.

W-2263

LIN28 PROMOTES MAMMALIAN TISSUE REPAIR BY REPROGRAMMING METABOLISM

Ng Shyh-Chang[1], Hao Zhu[2], Tarja Yvanka de Soysa[1], Gen Shinoda[1], Marc T. Seligson[1], Kaloyan Tsanov[1], John Asara[3], Lewis C. Cantley[4], George Q. Daley[1]

[1]Harvard Medical School/Boston Children's Hospital, Boston, MA, United States, [2]UT Southwestern, Dallas, TX, United States, [3]Beth Israel Deaconess Medical Center, Boston, MA, United States, [4]Weill Cornell Medical College/New York Presbyterian Hospital, New York, NY, United States

Robustness of tissue repair and regeneration declines with aging, but the mechanisms relating juvenility and tissue repair remain unclear. The pluripotency factor Lin28, a highly conserved heterochronic gene expressed early in development, controls juvenility and the onset of developmental milestones in animals from worms to humans. In the highly regenerative mammalian liver, genetic deletion of either of the Lin28a/b paralogs impaired oval cell-mediated liver regeneration after chemical injury. To determine if enforced re-expression of Lin28 can promote repair, we examined the effect of overexpressing Lin28a on tissue regeneration in adult mice. After shaving, Lin28a rapidly induced hair regrowth and anagen during the second telogen phase, and after tissue wounding, led to accelerated healing in the adult pinnae and neonatal digits. We assessed the role of let-7, a major downstream target of Lin28, through miRNA gain and loss of function experiments in vivo. Although let-7 overexpression inhibited both liver regeneration and pinnal repair, let-7 knockdown alone failed to enhance tissue repair, suggesting let-7 suppression is necessary but insufficient to account for Lin28-mediated tissue repair. Indeed, we found that Lin28a alters cellular metabolism in vitro and in vivo by directly binding and enhancing the translation of mRNAs for enzymes that mediate glycolysis and oxidative phosphorylation. Surprisingly, pharmacologic inhibition of oxidative phosphorylation abrogated Lin28a-mediated effects without compromising normal tissue repair. Our data indicate that Lin28 enhances tissue repair by programming for a juvenile state of cellular bioenergetics, and suggests that drug modulation of tissue bioenergetics might enhance wound healing.

FUNCTIONAL TISSUE ENGINEERED CORNEAL ENDOTHELIUM DERIVED FROM HUMAN IPS CELLS

Satoru Yoshida[1], Shin Hatou[1], Kazunari Higa[2], Miyuki Yasuda[1], Hideyuki Miyashita[1], Kazuo Tsubota[1], Shigeto Shimmura[1]

[1]Department of Ophthalmology, Keio University School of Medicine, Tokyo, Japan, [2]Department of Ophthalmology, Tokyo Dental College Ichikawa General Hospital, Chiba, Japan

Corneal endothelial dysfunction remains a common indication for keratoplasty, accounting for half of the total number of such procedures. Keratoplasty using donor cornea includes problems such as immunological rejection. To bypass these problems, we examined application of induced pluripotent stem cells (iPSCs) to engineer artificial corneal endothelium. Corneal endothelium as well as corneal stroma originates from cranial neural crest cells (NCCs). On the basis of these findings, we first tried to differentiate human iPSCs into neural crest cells (iPS-NCCs). Subsequently, the iPS-NCCs were cultured in the specific endothelium-inducing medium. After one week of culture, monolayer of IPSCs-derivd tissue engineered corneal endothelium (iTECE), which shows hexagonal mosaic pattern mimicking the human corneal endothelium was obtained. RT-PCR revealed the expression of characteristic markers of corneal endothelium in iTECE. The markers examined were Na,K-ATPase alpha1-subunit (ATPA1A), carbonic anhydrase 2 (CAR2), Na,HCO3 co-transporter (SLC4A4), collagen IV (CLO4A2), and collagen VIII (COL8A2). We next measured the pump function attributable to Na,K-ATPase activity using an Ussing chamber. As a result, significantly higher Na,K-ATPase pump activity of iTECE sheet compared to that of cultured human corneal endothelial cell sheet, 372.5 μA/cm^2 and 55.9 μA/cm^2 respectively, was observed. Finally, we transplanted iTECE sheets into rabbit cornea to evaluate in vivo pump function of iTECE. The iTECE transplanted rabbit cornea maintained transparency and usual corneal thickness (350 μm), whereas control corneas without TECE showed marked edema and increased corneal thickness (1105.8 μm). Thus, we successfully produced iTECE from human iPSCs, which has sufficient pump function to maintain corneal thickness in vitro and in vivo.

W-2266

DECELLULARIZED CAPRINE TENDON FOR BIOENGINEERING APPLICATIONS IN VITRO

Annie -. John, Thasneem E K Hadi, Francis B. Fernandez
Transmission Electron Microscope Laboratory, Sree Chitra Tirunal Institute for Med. Sciences & Technology, Trivandrum, India

Tendons play a key role in force transmission in the musculoskeletal system and hence are subject to acute forces. The ability of tendons to tolerate repeated force application renders it ideal for use as a decellularized scaffold to replace similar tissues in a biological milieu. On the contrary, tendons are susceptible to load induced tendinopathy, traumatic dissection & similar pathologies and thus a common problem in both occupational and athletic settings. But majority of the tissue is avascular & cell content has low proliferation rates making healing slow post-injury resulting in the formation of inferior scar tissue or fibrous adhesions, which increases the risk of re-injury at the repair site.
Available scaffolds for tendon repair include both biological scaffolds, obtained from mammalian tissues (Alamo tissue service, RTI biologics, etc.), and synthetic scaffolds. Tissue-based scaffolds are an option as ideal biologic scaffolds for de novo construction of damaged tendons. In decellularized tendon tissue the native ECM organization is preserved which provides tolerance for loading at critical points. Tissue engineering by adding stem cells to this pre-prepared scaffold will stimulate the generation of load oriented ECM as well as conditioning of the scaffold to the demands at the site of transplantation.
Caprine tendon tissue (goat Achilles tendon - abattoir sources) was decellularized with Triton-X 100 (1% in Tris buffer, pH-7.4) treatment in combination with continuous agitation and rinses with distilled water and 70% (v/v) ethyl alcohol. Thereafter decellularized tendon scaffold (DTS) along with non-treated fresh tendon scaffold (NTS) was fixed in 10% buffered formalin and 3 % phosphate buffered gluteraldehyde respectively for the study of structural changes if any, after decellularization. Light Microscopy, Scanning and transmission electron microscopy showed characteristic collagen patterns that remained undisturbed after decellularization treatment and absence of cells, nuclei or collagen degradation. NTS and DTS were further subjected to collagenase degradation assay which indicated 43% weight reduction in NTS while in DTS weight reduction was 70%. The lack of cellular inhibition & open architecture as a result of the decellularization process renders the DTS more susceptible to collagenase attack. Contact angle studies showed both surfaces to be hydrophilic (NTS at 49.8 and DTS at 57.4).
Prior to application, it is a prerequisite that decelluarised tendon is non-cytotoxic and cytocompatible. Cytotoxicity (MTT assay with HeLa cells) of the decellularized tissue showed cellular activity well above recommended limits at 24 & 48 hrs. In direct contact assays with L929 fibroblasts, cells attached and grew profusely on the scaffold with

time. In short, the method was successful in creating a non-cytotoxic and cytocompatible ECM scaffold appropriate for tendon bioengineering applications, yet to be validated in a rabbit injured tendon model.
Restoration of normal structure and function of injured tendons represents one of the most challenging areas in Orthopaedics where treatments are largely palliative. Decellularised tendon with stem cells is a promising treatment for the regeneration of injured tendon in the armamentarium of the physician or surgeon.

W-2267

MESENCHYMAL STEM CELLS ATTENUATE HEPATIC FUNCTION IN DECELLULARIZED WHOLE ORGAN SCAFFOLDS TO GENERATE TRANSPLANTABLE LIVER GRAFTS

Yoshie Kadota[1], Hiroshi Yagi[1], Alejandro Soto-Gutierrez[2], Taizo Hibi[1], Yuta Abe[1], Katsunori Tanaka[1], Minoru Kitago[1], Masahiro Shinoda[1], Hideaki Obara[1], Osamu Itano[1], Minoru Tanabe[1], Yuko Kitagawa[1]
[1]Surgery, Keio University, Tokyo, Japan, [2]Surgery, University of Pittsburgh, Pittsburgh, PA, United States

Aim: We assessed the influence of co-perfusion/culture of MSCs (mesenchymal stem cells) with hepatocytes in decellularized liver scaffolds to regenerate transplantable liver grafts which would give the sufficient functionality and viability of hepatocytes.
Methods: We first decellularized the isolated whole rat liver by perfusion of enzyme and non-ionic detergent with the best concentrations for the removal of cellular components and the preservation of native extracellular matrix. Secondly, the acellular translucent matrix scaffold, which was composed of the liver-specific extracellular matrix components and vascular networks, was recellularized with rat hepatocytes and MSCs sequentially via portal vein. To achieve maximum hepatocyte function and viability, we modified; 1) total number of cells, 2) proportion of cells, 3) volume of scaffold, and 4) reseeding methods. Several methods were examined to prevent infection of the perfusion-cultured graft. The two different cell types were tracked to see their locations in the scaffold at different time points by CellTracker Kit and immunofluorescent staining. To evaluate the influence of co-perfusion/culture of MSCs with hepatocytes, we compared the two groups of whole liver scaffolds which were recellularized by; 1) only hepatocytes, 2) hepatocytes and MSCs, of their engraftment and repopulation at day 2, 4 and 6. They were evaluated by histological, biochemical and genetic analyses.
Results: We achieved whole-organ decellularaization for rat livers with the optimal concentration of 0.05% trypsin and 0.1% Triton X-100, which showed the sufficient cell removal and preservation of native structures. The efficient engraftment and survival of hepatocytes and MSCs were demonstrated with a total of 50 X 10^6 hepatocytes and 10 X 10^6 MSCs (20% of hepatocytes), which were mixed and infused into median lobe of the whole liver through portal vein, in three steps, at 2 hours intervals. Also, we could minimize the infection risk of perfusion culture system by antimicrobial and antifungal antibiotics and exposure to ultraviolet-C for the matrix scaffold. Histological findings showed that hepatocytes were aligned as the original hepatic cords from portal vein through central vein. The liver scaffold which was recellularized by co-perfusion/culture of MSCs showed clusters of well-integrated hepatocytes in which MSCs were distributed well with good viability and expressed adhesion molecule markers. In addition, hepatocyte and vascular related growth factors as well as hepatic sinusoid specific markers were expressed along with the decellularized vascular walls, especially around the portal areas of the scaffold, where MSCs were repopulated that was demonstrated by cell tracking method. The graft in which MSCs were co-perfused/cultured showed the less apoptosis of hepatocytes and well-maintained ALB/UREA syntheses as well as higher hepatic gene expressions.
Conclusion: The combination of decellularized whole liver scaffolds and MSCs could show the
potential to create the liver grafts with long-term functionality and viability of engrafted hepatocytes as the result of cell-to-cell and cell-to-matrix interactions that might be catalyzed by their original humoral factors. This regenerated liver graft using MSCs will add new insights for liver regeneration and future clinical use of the decellularized liver matrix scaffold as a bioartificial liver graft.

MURINE DECELLULARIZED HEART MATRICES MAINTAIN VIABILITY AND PROLIFERATION OF HUMAN IPS CELLS, BUT ALSO INDUCE THEIR DIFFERENTIATION TOWARDS SPECIFIC CELL FATES

Juliana L. Carvalho[1], Pablo H. Carvalho[2], Carolina R. Oliveira[1], Dawidson A. Gomes[1], Alfredo M. Goes[1]
[A]Biochemistry and Immunology, [B]Clinical and Surgery, [1]Federal University of Minas Gerais, Belo Horizonte, Brazil

Decellularized matrices (DM) are in vogue for tissue engineering applications, due to their favorable chemical composition and perfect tridimensional structure. In addition, it has been described that ECM controls several events in cell biology, such as cell adhesion, proliferation, survival and differentiation. In the present study, we aimed to investigate the biocompatibility of DM and their potential differentiation effects over human iPS cells. Murine decellularized heart matrices (mDhM) were produced through SDS/Triton X-100 protocol, and were tested to: genomic DNA content; microscopic structure and cell content; collagen I and laminin preservation; cytotoxicity; iPS cell adhesion and differentiation induced-effects. Our results indicate that mDhM were virtually 100% decellularized, as no genomic DNA was detected by Nanodrop® quantification and PCR. Corroborating those results, histological analysis performed after Hematoxilin/Eosin, as well as Gomori Trichrome showed no cell nuclei in the matrix, which preserved its microtructure. When used as a scaffold for undifferentiated iPS cells, mDhM induced no significant cytotoxicity, as indicated in MTT assay. iPS cell adhesion wasn't affected by the substitution of Matrigel to mDhM, suggesting its applicability as a scaffold for tissue engineering purposes. Finally, we show that mDhM promote differentiation of human iPS cells, even when cultured in medium for maintenance of their undifferentiated status. Such event was characterized both by PCR and immunofluorescence and underscores the loss of expression of pluripotency markers Oct-4, Nanog and Telomerase reverse transcriptase, as well as the gain of expression of differentiation markers mainly from endoderm (Alpha-fetoprotein and SOX-17) and mesoderm lineages (Brachyuri and cytokeratin-8). Real time PCR is currently being performed in order to determine which embryonic germ layer has been enriched by differential gene expression. Pluripotent stem cells hold great promise for tissue engineering applications due to their high proliferative potential and broad differentiation capacity. Currently, though, the risk of teratoma formation following their injection *in vivo* still hinders their application in the clinic, with only two clinical trials approved by FDA so far. The use of scaffolds for pluripotent stem cell-based tissue engineering applications should, therefore, provide safety measurements for preventing teratoma formation. Herein, we propose that differentiation-inducing scaffolds can be suitable for pluriptent stem cell-based tissue engineering, in order to prevent the injection of undifferentiated cells *in vivo*. In addition, DM provides several classes of differentiation cues, which, sensed by the cells, may promote more successful differentiation event resulting in mature and functional cells.

REGENERATION OF VASCULARIZED DENTAL PULP-LIKE TISSUE BY CO-CULTURING DPSCS AND ECS IN A PEPTIDE HYDROGEL SCAFFOLD

Waruna L. Dissanayaka[1], Chengfei Zhang[1], Kenneth M. Hargreaves[2], Lijian Jin[1]
[1]University of Hong Kong, Sai Ying Pun, Hong Kong, [2]University of Texas Health Science Centre at San Antonio, San Antonio, TX, United States

Objectives: To investigate vascular network formation and differentiation of mono- or co-cultured human dental pulp stem cells (DPSCs) and human umbilical vein endothelial cells (HUVECs) within a three-dimensional peptide hydrogel scaffold (PHS); and to utilize this prevascularized construct for dental pulp regeneration in an in-vivo model.
Methods: Monocultures and combinations of co-cultures (3:1, 1:1, 1:3) of DPSCs and HUVECs were encapsulated in different concentrations (0.5%, 0.25%, 0.15%) of PHS (BD-Biosciences, Bedford, MA). DPSCs and HUVECs were transfected with green fluorescent protein and red fluorescent protein respectively using pre-made lentiviral particles (GenTarget Inc, San Diego, CA) before encapsulation. Cellular morphologies and 3-dimensional organization of cultures within PHS were monitored using confocal microscopy. Cell viability was assessed using a live/dead viability assay kit at day 7 and 14. Cell cultures within PHS were induced for odonto/osteogenic differentiation (up

to 21-days), examined for alkaline phosphatase (ALP) activity (ALP quantification assay) and mineralization (Von-Kossa staining). Cell-scaffold constructs were injected into the canal space of tooth-root fragments and implanted into the subcutaneous space on the back of 6- 8-week-old female severe combined immunodeficient mice. Three months after the transplantation, the mice were euthanized and the tooth fragments were removed for histological (Haematoxylin and eosin) and immunohistochemical (human mitochondria and CD31) analysis. Experiments were conducted in triplicate using DPSCs from three different donors and statistically analysed (ANOVA).
Results: Live/dead assay revealed 0.15% as the optimum PHS concentration with a significantly high survival of HUVECs compared to 0.5% and 0.25% PHS. In monocultures, DPSCs survived and grew faster than HUVECs. In co-cultures both cells survived well and HUVECs formed an extensive vessel-like network throughout the PHS compared to HUVEC monocultures where it failed to form any vessel-like structures. This finding suggested that co-culture inhibits HUVECs apoptosis and secretes angiogenic factors to promote vessel-like network formation. At higher endothelial cell counts, the density of vessel-like structures was low and DPSC:HUVEC 3:1 was found as the optimum ratio. ALP activity of cells in co-culture was higher than that of DPSCs in monocultures ($p<0.05$). Despite the ratio, all the co-cultures showed higher amount of mineralization compared to monocultures. The longitudinally sectioned root constructs revealed that 1/3-1/2 of the canals was filled with highly vascularised regenerated pulp-like tissue in both DPSC alone and DPSC-EC co-cultured groups. Majority of the cells in regenerated tissue stained positively for antibodies against human mitochondria confirming the human cell origin of them. Positive staining for CD31 was seen in cells lining the blood vessels in the regenerated tissues, suggesting that the transplanted endothelial cells were responsible for the newly formed vasculature.
Conclusion: These findings indicate that PHS promotes angiogenesis and osteo/odontogenic differentiation in-vitro and can successfully be used for engineering vascularised-pulp tissues in-vivo.

W-2272

ODONTOGENIC DIFFERENTIATION OF DENTAL PULP-DERIVED STEM CELLS ON TRICALCIUM PHOSPHATE SCAFFOLDS

Mohamadreza Baghaban Eslaminejad, Sima Bordbar, Hamid Nazarian
Department of Stem Cell and Developmental Biology, Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Iran, Tehran, Iran, Islamic Republic of

The regeneration of dental-related tissue is a major problem in dentistry. Thus it is beneficial to develop dental constructs that are fabricated with dental pulp stem cells (DPSCs) and an appropriate scaffold. The present study investigates the level of odontogenic differentiation of human DPSCs on tricalcium phosphate (TCP) scaffolds. Pulp stem cells from human third molars were isolated, culture-expanded through several successive subcultures and characterized in terms of surface markers as well as differentiation potential. The passaged-3 cells were then loaded onto the scaffolds and treated with odontogenic supplements (OS) that included vitamin D3 for a period of 21 days. The scaffolds were Kasios TCP which is commercially available in the form of granules with 3 mm dimensions, average pore size of 200-500 µm and a mean porosity of 60%-80%. DPSCs cultivated on TCP without OS, a monolayer culture treated with OS, and normal pulp tissue were the controls. To determine the loading efficiency, a few hours after cell loading we quantified the cells present within the culture medium. The scaffolds were also prepared for light microscopy (LM) and scanning electron microscopy (SEM) to observe the cells within the scaffold. Furthermore, we compared the groups in terms of odontogenic differentiation markers. According to our results, the loading efficiency was 80%. Based on the representative section prepared from the scaffold/cell construct, DPSCs appeared to occupy the scaffold pore spaces. In SEM images, the cells were observed to establish an attachment with scaffold surfaces. Alkaline phosphatase (ALP) activity, amount of culture mineralization, as well as the expression levels of dentin sialophosphoprotein (DSPP) and dentin matrix acidic phosphoprotein (DMP1) genes tended to be significantly high in the three-dimensional (3-D) cultures treated with OS compared to those 3-D cultures without OS and the monolayer culture with OS ($p<0.05$). The differentiation level of 3-D cultures was considerably lower than that of pulp tissue extracted from third molars ($p<0.05$). 3-D culture on TCP without OS showed a level of differentiation indicating an odontogenic property of TCP biomaterial. In conclusion, the 3-D culture system improves

odontogenic differentiation of DPSCs. The differentiation level of the cells in 3-D culture is significantly lower than that of odontoblasts present in pulp tissue. TCP biomaterial possesses an odontogenic-inducing property.

W-2273

IN VIVO TISSUE FORMATION BY MESENCHYMAL STEM CELLS DERIVED FROM HUMAN EXTRACTED IMMATURE TEETH AND MATURE WISDOM TEETH.

Yuichi Tamaki
Department of Developmental and Regenerative Dentistry, The Nippon Dental University, Tokyo, Japan

Introduction: Mesenchymal stem cells are found in several different dental tissues, including dental pulp, periodontal ligament, apical papilla and dental follicle. In our previous study, we found that DSCs have higher proliferative potential than bone marrow-derived stem cells (BMSC). Dental stem cells (DSCs) have multipotent capacity of differentiate into various cells such as osteoblasts, adipocytes and even neuronal cells. However, it is not clear whether the origin (anatomical or tooth developmental stage) of these cells influences the type of tissue produced. We aimed to investigate the tissue forming potential of DSCs through the transplantation experiments in vivo.
Methods: Stem cells isolated from the apical papilla (APSC) and dental follicle (DFSC) of immature teeth and the periodontal ligament (PDLSC) and dental pulp (DPSC) of mature wisdom teeth, were cultured for three passages before use. Cells were assessed for telomerase activity and expression of periodontal tissue related genes (F-spondin, tenascin-N and periostin) compared with BMSC by Quantitative Telomerase Detection Kit (Biomax) and RT-PCR. To analyze the capacity of the dental stem cells to form hard tissues, we combined each cell type with hydroxyapatite (HA) particles within a collagen gel scaffold. This construct was then transplanted subcutaneously into CB.17 ICR-scid immunocompromised mice. For histological examination, the samples were collected 16 weeks after the transplantation and were fixed with 10% neutral buffered formalin. They were then decalcified, embedded in paraffin, and cut into serial sections (5 μm). The specimens were stained with hematoxylin and eosin and Masson's trichrome. To examine the formed tissue, immunohistochemistry was performed using antibodies against human specific vimentin, periostin, dentin sialoprotein (DSP), and bone sialoprotein (BSP). The primary antibody was omitted during immunostaining as a negative control.
Results: Telomerase activity was higher in APSC and DFSC than in other cell types. Expression of periodontal tissue related genes differences between cell types in F-spondin and tenascin-N expression. DFSC expressed F-spondin higher than the others. Histological analysis showed that all of the DSCs formed a hard tissue structure along with the surface of HA. For immunohistochemical analyses, they were entirely positive for vimentin and periostin antibodies, while they were partially positive for BSP and DSP antibodies.**Conclusions**: These results suggest that DSCs, especially APSC and DFSC, have capacity of forming hard tissues around a suitable scaffold. Thus, immature teeth appear to be an excellent source of cells for targeted dental hard tissue regeneration applications.

DERIVATION OF DEFINITIVE ENDODERM -LIKE CELLS FROM HUMAN EYE DERIVED INDUCED PLURIPOTENT STEM CELLS CULTURED IN TWO OR THREE DIMENSIONAL CELL CULTURE ENVIRONMENTS

Mohammad Massumi[1], Elham Hoveizi[2], Farzaneh Pourasgari[3]
[1]National Inst of Genetic Engineering and Biotechnology, Tehran, Iran, Islamic Republic of, [2]Biological Sciences, Tarbiat Moallem University, Tehran, Iran, Islamic Republic of, [3]Biotechnology, Razi Vaccine and Serum Research Center, Karaj, Iran, Islamic Republic of

Due to lake of immunological incompatibility and ethical issues, human induced pluripotent stem cells (hiPSCs) have been considered as potent source for disease modeling, cell replacement therapy and pharmacological screening. In generation of insulin-producing cells from iPSCs, derivation of definitive endoderm (DE) cells is the most critical stage. Furthermore, to generate a specialized tissue *in vitro* that can recapitulate bona fide tissue, culturing and differentiation of cells in a three dimensional (3D) culture environment is required. In the present study, first we established novel iPS cells, ECiPS, which directly reprogrammed from human Eye Conjunctiva-derived Mes-

enchymal Stem Cells (EC-MSCs). To provide 3D culture system PLA/gelatin nanofibrous scaffolds were fabricated. Then ECiPS cells were cultured either on the gelatin (2D) or PLA/gelatin electrospun scaffolds (3D) and induced into DE cell programming fate by specific signaling molecules. Expression analyses of DE-specific markers in mRNA and protein levels confirmed high expression of these markers in ECiPS-derived DE-like cells differentiated in either the 2D or 3D cultural environments. However the level of increase in the ECiPS-derived DE-like cells cultured/differentiated in the PLA/gelatin electrospun scaffolds was significantly higher than expression in the ECiPS-derived DE-like cells cultured/differentiated in the 2D culture system. In conclusion, culturing/differentiation of iPSCs in a 3D culture environment could result in efficient derivation of DE-like cells in comparison to cells cultured/differentiated in a 2D culture system. The result of this study may have impact in future tissue engineering of diseases that implicate DE-derived organs.

MOUSE EMBRYONIC STEM CELL-DERIVED IN VITRO MODEL OF HEART, LIVER, AND PANCREAS ON MICROFLUIDIC DEVICE

Yoh-ichi Tagawa[1], Miho Tamai[1], Yoichi Fujiyama[2]

[1]Tokyo Institute of Technology, Yokohama-shi, Japan, [2]Shimadzu Corp., Kyoto, Japan

There are multicellular organisms such as mammalians consisting of a variety of tissues and organs. However, its ontogeny starts from a fertilized egg, a single cell, dividing and differentiating, and finally developing to a single organism having tissues and organs. Blastocyst, a 3.5 day embryo in mouse, consists of trophectoderm and inner cell mass (ICM). The body of the organism is develops from the ICM which can differentiate to three germ-layers. Embryonic stem (ES) cells, having pluripotency to be able to differentiate to three germ-layers, are derived from the ICM.

We have established the murine ES cell-derived *in vitro* model of heart, liver, and pancreas, iHLP^{mES}, consisting of not only beating cardiomyocytes, liver tissue of hepatocytes and endothelial networks, but also pancreatic islets of insulin and glucagon producing cells. The iHLP^{mES} was differentiated from the visceral endoderm-like layer having embryoid body prepared from mouse ES cell lines, E14.1 or ST1. Glucose level in the medium of the iHLP^{mES} model decreased at high insulin, while increased at the high glucagon concentration, suggesting that glucose level could be controlled in the model. Furthermore, multidrug resistance-associated protein 2 and organic anion-transporting polypeptide 2 were confirmed to be functionable in the iHLP^{mES} model, but not in the primary culture of hepatocytes, suggesting that the iHLP^{mES} model was succeeded in having the hepatic multi-polarities. Now, we are trying to equip the iHLP^{mES} with medium-flow system using micro-device like the blood, expecting close to the *in vivo* metabolism system, as a minimal mammal system.

HYPOXIC CONDITIONED MEDIUM OF MESENCHYMAL STEM CELLS ENHANCED BONE REGENERATION IN RAT CALVARIAL BONE DEFECTS THROUGH REGULATION OF INTEGRIN α-1 TARGETED-MICRORNA-125B

Yu Jin Jung

Institute of Catholic Integrative Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea., Incheon, Korea, Republic of

Hypoxic conditioned medium of mesenchymal stem cells enhanced bone regeneration in rat calvarial bone defects through regulation of integrin [[Unsupported Character - Symbol Font ]]-1 targeted-microRNA-125b

Yu Jin Jung[a], Hyun-joo Ham[a], Sang In Park[a], Yoonjin Bae[a], Moon-Seo Park[a], Yong-An Chung[a], Lee-So Maeng[a], Woochul Chang[a]

[a]Insitute of catholic Integrative Medicine (ICIM), Incheon St. Mary's Hospital, The Catholic University of Korea.

The use of mesenchymal stem cells (MSCs)-conditioned medium (CM) may be a feasible approach to regenerate bone defect in rat through secreting various factors of MSCs including cytokines, chemokines and growth factors. In this study, we investigated that CM collected under hypoxic culture condition can affect bone regeneration through enhanced migration and adhesion of rat MSCs (rMSCs). rMSCs treated of hypoxic-CM (HCM) showed a significantly increased migration ability compared to the rMSCs treated of normoxic CM (NCM). Also the rMSCs treated of HCM showed increased expression of integrin alpha-1 (ITGA1) which plays a critical role in control of cell migration. The upregulation of ITGA1 was induced by changed expression of the ITGA1 targeted-microRNA-125b on rMSCs because microRNAs are key regulator in various biological functions including cell differentiation, survival and migration by regulating gene expression. Rat calvarial defect model was administrated in three different groups using one of the following graft materials: HCM/greenplast (HCM/g), NCM/greenplast (NCM/g), and DMEM/greenplast (DMEM/g). After 4 and 8 weeks, newly regenerated bone was evaluated using computed tomography (CT) and calcein fluorochrome. CT and calcein analysis indicated that the newly regenerated bone in HCM/g group have enhanced compared to the other groups. These results suggest that HCM may be improved bone regeneration through regulation of ITGA1 targeted-microRNA-125b by secretomes of rMSCs under hypoxic condition

HUMAN ENDOMETRIAL MESENCHYMAL STEM CELLS MODULATE THE TISSUE RESPONSE AND MECHANICAL BEHAVIOUR OF POLYAMIDE MESH IMPLANTS FOR PELVIC ORGAN PROLAPSE REPAIR

Caroline E. Gargett[1], Daniela Ulrich[1], Sharol L. Edwards[2], Jacinta F. White[3], Christopher Su[3], Ker Sin Tan[1], Anna Rosamilia[4], John AM Ramshaw[3], Jerome A. Werkmeister[3]

[1]The Ritchie Centre, Monash Institute of Medical Research, Melbourne, Australia, [2]Materials Science and Engineering, CSIRO, Geelong, Australia, [3]Materials Science and Engineering, CSIRO, Melbourne, Australia, [4]Obstetrics and Gynaecology, Monash University, Melbourne, Australia

Pelvic organ prolapse (POP) is the herniation of bladder, bowel and/or uterus into the vagina causing urinary incontinence and sexual dysfunction. POP results from childbirth injury. POP occurs in 25% of all women and 11-19% of women will be treated for POP by reconstructive surgery with or without polypropylene mesh. Complication rates approach 30% and the FDA has posted 2 warnings on the use of polypropylene mesh for vaginal repair surgery. We have identified and characterised human mesenchymal stem cells (MSC) from a novel source, the highly regenerative endometrial lining of the uterus. Perivascular endometrial MSC (eMSC) can be prospectively isolated from endometrial biopsies in the CD140+CD146+ subpopulation (1) or by a single marker, W5C5 (2). Our objective was to use a tissue engineering approach to assess the in vivo biological and biomechanical behaviour of a new synthetic polyamide/gelatin composite mesh (3) seeded with human eMSC in a subcutaneous rat model of wound repair.
Human eMSC were isolated from collagenase-dissociated endometrial tissue using W5C5-labelled magnetic beads, expanded in culture to passage 6, labelled with a fluorescent dye (DiO) and seeded onto fibronectin coated meshes (polyamide/gelatin composite, 25x10 mm) (3) at 500,000 cells/scaffold. Cell-seeded meshes were subcutaneously implanted dorsally in immunocompromised nude rats for 7, 30, 60 and 90 days (n=8/group). Controls received meshes without cells. Explanted samples were analysed by flow cytometry to detect DiO-labelled cells, by immunohistochemistry to assess foreign body reaction and tissue integration. Collagen III/I ratios were quantified by chemical assays, collagen organisation by birefringence and uniaxial tensile testing by Instron.
Implanted meshes were well tolerated and there were no mesh erosions. Labelled eMSC were detected on the mesh up to 14 days post-implant. Meshes with and without cells were equally infiltrated with CD45+ leukocytes, which subsided by 90 days in cell-seeded mesh, but not in mesh alone ($P<0.05$). There were similar temporal differences in CD68+ macrophage infiltration and the M1 and M2 macrophage content differed between mesh seeded with or without cells ($P<0.05$). In cell-seeded mesh, neovascularisation was greater at 7 days than controls ($P<0.05$). New collagen was observed in meshes with and without eMSC. At 7 and 90 days, the meshes seeded with cells were less stiff than those without cells.
This tissue engineering approach reduced the number of inflammatory cells around implanted mesh filaments and promoted neovascularisation, suggesting that eMSC exert an anti-inflammatory effect, promoting wound repair

with minimal fibrosis, and new tissue with more compliant properties. EMSC seeding improves polyamide/gelatin composite mesh biocompatibility and may provide an alternative novel approach for the future treatment of POP.

UMBILICAL CORD BLOOD-DERIVED MESENCHYMAL STEM CELLS TRANSPLANTATION WITH THIOLATED HYALURONIC ACID/PEG-DA HYDROGEL IMPROVES CARDIAC FUNCTION IN A RAT MYOCARDIAL INFARCTION MODEL

Byung-Jae Kang[1], Seul Ki Lee[2], Yiming Shen[2], Hwan Kim[4], Sunyoung Jung[3], Nathaniel SukYeon Hwang[4], So Yeong Lee[2], Mincheol Choi[3], Pan Dong Ryu[2], Je-Yoel Cho[1]

Mesenchymal stem cell (MSC) transplantation is a newly developed
strategy for cardiac tissue regeneration after myocardial infarction (MI). However, this application is limited by low retention and survival rate of transplanted cells. To improve the efficacy of umbilical cord blood (UCB)-derived MSC therapy for MI, we investigated whether thiolated hyaluronic acid/polyethylene glycol diacrylate (tHA/PEG-DA) hydrogel mixed with UCB-MSC could improve cardiac function and inhibit left ventricle (LV) remodeling in a rat model of MI. tHA/PEG-DA hydrogel alone, MSC alone or tHA/PEG-DA hydrogel seeded with MSC were injected into the infracted myocardium immediately after coronary artery ligation in male rats. Injection of PBS served as control. Five weeks after the MSC transplantation, the echocardiogram showed that injection of UCB-MSC with hydrogel increased the LV ejection fraction and fractional shortening. Histological analysis indicated that injection of UCB-MSC with hydrogel induced a decrease in MI size and an increase in scar thickness, and subsequently prevented scar expansion. This study indicates that tHA/PEG-DA hydrogel could enhance the therapeutic effect of MSC transplantation for MI and therefore the injection of UCB-MSCs with this hydrogel may be a promising strategy in the treatment of MI.

BIOLOGICAL BEHAVIOR OF MESENCHYMAL STEM CELLS ON POLI-ε-CAPROLACTONE FILAMENTS AND A POTENTIAL STRATEGY FOR TISSUE ENGINEERING OF PERIPHERAL NERVES

Alvaro C. Ruiz, Rosalia M. Otero, Victor T.R. Resende
Institute of Biophysics Carlos Chagas Filho, Federal University of Rio de Janeiro, Rio De Janeiro, Brazil

Background: Peripheral human nerves fail to regenerate across longer tube implants, most likely because implants lack the microarchitecture of native nerves, including bands of Bungner, that guide selectively regrowing axons. Bone marrow derived cells can contribute to the regeneration of the peripheral nervous system in many aspects under cell therapies approach due to the secretion of soluble factor, for instance. Our previous works showed that microstructured biomaterial filaments are capable of inducing bands of Bungner and that bone marrow cells induce regeneration acting on both neuronal and glial cell populations of the peripheral nervous system (PNS). Therefore, to optimize tubular implants by integrating artificial bands of Bungner and a biological component capable of en-

hancing that regenerative capacity, we study the interaction between poly-caprolactone (PCL) filaments and bone marrow mesenchymal stem cells (MSC).
Methods: For *in vitro* experiments, rat's MSC were placed on PCL filaments previously treated with plasma O_2, poli-D-lysine and laminin. Cells were plated in three different concentrations, $2x10^5$, $2x10^6$ and $8x10^6$ cells/mL, in DMEM F-12 plus 10% fetal bovine serum. After 48h of incubation, the adhesion profile, viability and proliferation capacity of those cells, in contact with the filaments, were analyzed. Adhesion profile was analyzed by immune marking with CD-90 antibody, viability by staining with Calcein AM and Ethidium homodimer-1 and proliferation by immune marking with KI-67 antibody. We also plated rat's adult Schwann cells at the concentration of $5x10^5$ cells/mL on PCL filaments covered with MSC, 24h after the MSC plating, and let the co-culture go on for another 24h to analyze the feasibility of the Schwann cells-MSC-PCL filament system. Before plating, Schwann cells were incubated with CellTrace to assure distinction from the MSC. To test the potential for tissue engineering of peripheral nerves, embryonic rat's dorsal root ganglia were plated in contact with PCL filaments, with or without MSC. The samples were incubated for 4 days then immunolabeled for Neurofilament-200 antibody to analyze neurite extension.
Results: We observed that MSC appeared to be confined to lateral areas and ridges of PCL filaments, showing an alignment along the longitudinal microstructure. However, as we increased the plating concentration of cells, although the number of adherent cells also increased, the rate of alignment gradually decreased, as they agglomerated themselves. Cells showed high viability (90%) and their proliferation capability was not completely inhibited by the filaments. Schwann cells were able to adhere to the filaments plated with MSC maintaining also high viability (90%). Neurites were able to grow and extend over the surface of the PCL filaments when they were previously covered with MSC. Data were analyzed using one-way analysis of variance (ANOVA) with Neuman-Keuls post-test for multiple comparisons.
Conclusion: We provide evidence for the interaction between MSC, Schwann cells and PCL filaments, as they can constitute a stable system permissive for neurite extension and possibly events for the regeneration of the PNS. Moreover, we have ongoing experiments to further refine our study of the interaction between MSC, the peripheral nervous system and PCL filaments.

XENO-FREE EXPANSION AND DIFFERENTIATION OF HUMAN PLURIPOTENT STEM CELLS IN STIRRED SUSPENSION MICROCARRIER CULTURES

Yongjia Fan, Emmanuel (Manolis) S. Tzanakakis
Chemical and Biological Engineering, University at Buffalo, Buffalo, NY, United States

A major challenge for the translation of human pluripotent stem cells (hPSCs) to clinical applications -including tissue engineering and cell-based therapies- is the development of scalable bioprocesses affording the generation of medically relevant quantities of cellular material free of xenogeneic factors.
We employed a xeno-free stirred-suspension microcarrier bioreactor for the expansion of undifferentiated hPSCs and their directed commitment to particular fates. A vitronectin-derived peptide was conjugated on the surface of microcarriers. Initially different surface peptide densities were screened in static microcarrier cultures. Subsequently, cells were expanded for five successive passages in stirred suspension. The cells maintained a doubling time similar to that in regular dish cultures, with a 25-fold increase in cell concentration per passage, and exhibited higher than 85% viability. Moreover, the expression levels of pluripotency markers such as Nanog, Oct4 and SSEA4 were preserved as assessed by quantitative PCR, immunochemistry and flow cytometry. Cells cultured on the xeno-free microcarriers exhibited a normal karyotype. After multiple passages in the bioreactor, the cells were subjected to tri-lineage differentiation in static cultures. The resulting cells expressed markers of definitive endoderm (SOX17, FOXA2), mesoderm (MEOX, KDR1) and ectoderm (NES, TUBB3). Lastly, hPSCs propagated on peptide-conjugated beads were directed to mesoderm fate in stirred suspension. The fraction of differentiated progeny co-expressing MEOX1 and KDR was higher than that of cells in dish cultures. These results suggest that the peptide-conjugated microcarrier culture system developed in this study is suitable not only for expansion of self-renewing hPSCs but also for their guided commitment to specific phenotypes. We expect that this culture modality will contribute to

the design and development of stirred-suspension microcarrier bioreactors for the scalable propagation and differentiation of xeno-free hPSCs and their progeny intended for clinical therapies.

ISSCR 2013

Building 3-D µMuscle *in vitro* from Patterned Extracellular Matrix Stiffness and Adipose-derived Stem Cells

Yu Suk Choi, Ludovic Vincent, Andrew Lee, Matthew Ondeck, Kyle Kretchmer, Marek Dobke and Adam Engler

Cell patterning has been widely used to control stem cell shape, size, and adhesion but is typically limited to 2-D via selective deposition of extracellular matrix (ECM); however in tissues, cells are embedded in a 3-D matrix and also influenced by spatial differences in stiffness, which can result in patterned cell arrangements. Indeed, 2-D, fibronectin-coated, mechanically-patterned hydrogels provided more robust and prolonged cell patterns in serum-containing media than their ECM pattern-based counterparts. Adipose-derived stem cell (ASC) differentiation into myocytes was enhanced via patterning through improved alignment and cell fusion rate and number on stiffer regions of the matrix. Conversely, PC12 neuronal cells remain on soft regions of the hydrogel for prolonged culture time, suggesting that mechanical patterning can be used to build micro-tissues *in vitro* to examine more complex structures. To build stiffness-patterned micro-muscle cultures in 3-D, ASCs (or control myocytes) and PC12 neurons were encapsulated in stiffer or softer layers of a metacrylated-hyaluronic acid (MeHa) hydrogel impregnated with RGDS adhesive peptides, respectively. ASCs and myocytes filled stiffer layers with elongated, fused cells while neurons remained within softer layers though they exhibited interactions with myocytes. These data suggest the formation of micro-muscle cultures and the development of new 3-D platforms to create tissue engineered, innervated micro-muscles of neural and muscle phenotypes juxtaposed next to each other.

STRETCH-ACTIVATED ION CHANNELS IN HUMAN NEURAL STEM CELL MECHANOTRANSDUCTION

Medha M. Pathak[1], Jamison L. Nourse[2], Truc T. Tran[1], Lisa A. Flanagan[2], Francesco Tombola[1]

[A]Dept. of Physiology & Biophysics, [B]Dept. of Neurology, [1]University of California, Irvine, Irvine, CA, United States

Mechanical properties of the environment, such as rigidity, nanotopology, strain and shear forces are emerging as powerful modulators of stem cell behavior. A recent paradigm shift in stem cell biology has resulted from the discovery that variability in extracellular matrix stiffness is sufficient to direct cell fate and lineage specification. For example, in neural stem cells soft substrates promote neuronal specification whereas hard substrates promote glial specification. Although several molecular players that respond to substrate stiffness at focal adhesion zones have been identified, the mechanisms that direct downstream signaling pathways are not well understood. Here we examine the role of stretch-activated ion channels in matrix-elasticity-driven cell differentiation. Using patch clamp electrophysiological measurements we find that human neural stem/progenitor cells (hNSPCs) exhibit robust membrane-stretch-induced currents. High-speed Total Internal Reflection Fluorescence Microscopy reveals that activity of these channels elicits spontaneous Ca^{2+} transients in hNSPCs that are higher in amplitude on hard surfaces than on soft surfaces. Our results suggest that stretch-activated ion channels may be important for transducing substrate stiffness information into downstream pathways of differentiation in neural stem cells.

MECHANICAL AND PHENOTYPIC DYNAMICS OF 3D PLURIPOTENT STEM CELL MORPHOGENESIS

Melissa A. Kinney[1], Rabbia Saeed[1], Pablo A. Hidalgo[2], Boris Zakharin[2], Ari Glezer[2], Todd McDevitt[1]
[1]The Wallace H. Coulter Department of Biomedical Engineering, Georgia Institute of Technology and Emory University, Atlanta, GA, United States, [2]The George W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA, United States

Embryonic stem cells (ESCs) exhibit the capacity for the endogenous cell milieu to direct complex migration and self-organization, including the induction of the epithelial-to-mesenchymal transition, analogous to events mediating primitive streak migration during gastrulation. However, opportunities remain to develop a more complete understanding of dynamics of three-dimensional morphogenesis. The objective of this work is to quantitatively characterize the dynamics of the three dimensional ESC microenvironment, in order to control spatial and temporal aspects of pluripotent cell fate and morphogenesis and ultimately enable the derivation of complex, functional microtissues amenable to the replacement or regeneration of damaged tissue.
The multicellular aggregation kinetics of murine ESCs (D3) were precisely controlled via the combination of forced aggregation and subsequent rotary orbital suspension culture, which enables more uniform and reproducible embryoid body (EB) size, and thereby provides a controlled platform amenable to better understanding three-dimensional stem cell morphogenesis. Supplementation with BMP4 (10 ng/mL) increased expression of mesodermal genes (Gata2, Gata4, VE-cadherin) and induced an epithelial-to-mesenchymal transition, which was apparent within regions exhibiting distinct mesenchymal-like cell morphologies and α-smooth muscle actin (α-SMA) expression. The physical changes accompanying morphogenesis were subsequently analyzed to develop a quantitative understanding of the relationship between EB structure and morphogenesis. Mesenchymal EBs (+BMP4) exhibited significantly increased modulus ($p<0.05$) after 7 days of differentiation compared to those differentiated in basal serum-free media (169.2 ± 8.1, +BMP4; 110.5 ± 4.4 Pa, basal), and dynamically modulated viscoelastic characteristics during differentiation. Cytoskeletal perturbation (Y-27632; 10 μM) significantly decreased the modulus (>1.4-fold decrease), indicating that the stiffness of EBs is mediated in large part by cytoskeletal tension. Moreover, EBs differentiated in the presence of cytoskeletal agonists (jasplakinolide) and antagonists (Y-27632; latrunculin B) exhibited altered stiffness, in a culture condition specific manner; EBs differentiated under basal conditions in the presence of jasplakinolide (actin polymerization) and those treated with BMP4 and latrunculin B (actin depolymerization) exhibited increased stiffness compared to those without cytoskeletal perturbations, suggesting divergent roles for cytoskeletal dynamics in mediating ESC morphogenesis. EBs also exhibited significantly increased fluidic resistance ($p<0.05$ days 4-7 compared to days 2 and 3) during the first 7 days of differentiation, indicating that multicellular structural changes resulting from morphogenesis accompany increasingly limited molecular transport within EBs.
The results of these studies collectively indicate that biophysical properties of morphogenic EB microenvironments, including mechanical and transport characteristics, are dynamically altered as a result of phenotypic changes that transpire during ESC differentiation. Ultimately, understanding biochemical and biophysical tissue morphogenesis is expected to elucidate cellular interactions governing embryonic development and cell specification, and will inform strategies to generate functional tissue structures for regenerative therapies.

EVALUATION OF MICROCARRIER-BASED SUSPENSION CULTURES FOR HUMAN INDUCED PLURIPOTENT STEM CELLS

Sara M. Badenes[1], **Tiago G. Fernandes**[1], Annette Pusch[2], Simone Haupt[2], Carlos A.V. Rodrigues[1], Marie-Maud Bear[3], Martial Hervy[3], Maria Margarida Diogo[1], Oliver Brüstle[2], Joaquim M.S. Cabral[1]
[1]Department of Bioengineering, Instituto Superior Técnico, Lisbon, Portugal, [2]LIFE&BRAIN GmbH, Institute of Reconstructive Neurobiology, University of Bonn, Bonn, Germany, [3]CORNING Incorporated, CETC, Avon, France

A microcarrier-based suspension culture was explored for scale-up of human induced pluripotent stem cell (hiPSC) expansion in serum-free medium using synthetic peptide-acrylate surface[1] beads that were developed for long-term support of hiPSC self-renewal. Single-cell inoculation of hiPSCs on the microcarriers was optimized using a chemical inhibitor of the Rho-associated kinase pathway. This microcarrier system supported approximately 10-fold

expansion of the attached cells after 5 days in static culture. Scaling up the microcarrier-based system to 15mL-spinner flasks resulted in a 7-fold increase of the attached cells within 7 days. Initial cell densities of 50,000 and 25,000 cells/cm^2 were tested for a bead concentration of 3 g/l (corresponding to 100 cm^2/spinner). The percentage of cells that attached to microcarriers was very similar in both cases (32-35%). However, reducing the initial cell density resulted in a 2-times higher cell expansion. Envisaging the improvement of the scalability of the culture, multi-passage expansion on the microcarriers was attained by single-cell inoculation of harvested cells and also using confluent microcarriers as the inoculum, which was possible due to bead-to-bead cell transfer. After 4 passages of confluent microcarriers at a 1:1 ratio, a cumulative 339-fold expansion was achieved over 15 days of culture. In static as well as in dynamic cultures cells maintained their typical morphology and pluripotency-associated marker expression. We expect this technology to facilitate the standardized and automated scale-up of hiPSCs and their derivatives for further downstream applications including potential cell replacement therapies.

TISSUE ENGINEERING OF SMALL INTESTINE IN VIVO FOLLOWING SEEDING OF ORGANOID UNITS ON DECELLULARIZED INTESTINAL MATRICES

Panagiotis Maghsoudlou[1], Daniel E. Levin[2], Giorgia Totonelli[1], Allison L. Speer[2], Xiaogang Hou[2], Erik R. Barthel[2], Justin ML Dreyfuss[2], Christa N. Grant[2], Stavros Loukogeorgakis[1], Salvador Garcia[2], Simon Eaton[1], Tracy C. Grikscheit[2], Paolo De Coppi[1]
[1]University College London, London, United Kingdom, [2]Childrens' Hospital Los Angeles, Los Angeles, CA, United States

Aim of the study: Management of intestinal failure remains a clinical challenge and tissue engineering (TE), using an appropriate combination of scaffolds and cells could provide a therapeutic solution. We aim to create a neo-intestine that will be able to be connected to the host's blood supply.
Methods: We decellularized rat intestine using a previously described detergent-enzymatic methodology. We sterilised the scaffolds using UV irradiation, seeded with GFP+ organoid units derived from neonatal mouse intestine and transplanted in the omentum and subcutaneous space of irradiated NOD-SCID mice (n=12). Following 1 month we analyzed the seeded scaffolds using histology and immunofluorescence.
Main results: Following 1 cycle, all of the nuclear material in the scaffolds was removed as evident by histology and DNA quantification. In the luminal aspect, electron microscopy demonstrated an intact crypt-villus micro-architecture. After 1 month of in vivo growth, a number of the seeded rat scaffolds had grown into vascularized balls of 1cm diameter with simple cuboidal epithelium in the luminal side that was E-cadherin+ and villin+.
Conclusion: Transplantation of the rat scaffold in the omentum led to the formation of epithelium. We envisage cell seeding wherein the natural scaffold is surgically micro-anastomosed to the host's blood supply to enhance cell growth.

DIRECTED DIFFERENTIATION OF HUMAN PLURIPOTENT STEM CELLS TO CARDIOMYOCYTES WITH IMPROVED EFFICIENCY IN A DEFINED XENO-FREE SYSTEM

Abhirath Parikh, Emmanuel (Manolis) S. Tzanakakis
Chemical and Biological Engineering, Univ of Buffalo, Buffalo, NY, United States

Embryonic and induced pluripotent stem cells (PSCs) are an inexhaustible source of cardiomyocytes for treating myocardial infarction, a leading cause of morbidity and mortality. Recent advances in the development of patient-specific induced PSCs greatly improve the chances of clinical success. However, the lack of reproducible and efficient methods of cardiac differentiation poses challenges for the development of scalable bioprocesses. Some protocols require additional enrichment or purification steps and most of them are hampered by low differentiation

efficiencies thereby increasing the total operating costs. To resolve these issues, we have assessed different signaling pathways for efficient cardiac differentiation, and investigated methods for improving the yield of cardiomyocytes across a variety of human PSC (hPSC) lines.
Our approach for developing a cardiogenic differentiation method for hPSCs comprises three steps: (1) Stem cells were efficiently directed toward mesoderm-oriented primitive streak in a short timeframe characterized by high expression levels of BRACHYURY (T), MIXL1, EOMES and MESP1 assessed by PCR-gel electrophoresis and quantitative PCR. (2) Subsequently, these cells were coaxed along cardiovascular lineages expressing markers such as KDR, cKIT, Nkx2.5, GATA4, MEF2C. Beating cardiomyocytes were formed within a period of 7 days, and cardiac markers such as β-MHC, TBX20, MLC2a, ANF were strongly upregulated. The upregulation was higher than that seen in cells treated with conventional protocols for cardiogenic differentiation. (3) Finally, further maturation was promoted to cardiomyocytes with an increase in the expression of markers such as MLC2v and α-MHC. Corresponding upregulation of cardiac proteins was observed with western blot analysis. Cells also stained positive for cardiac proteins such as NKX2.5, GATA4, MEF2C, α-ACTININ, cardiac troponins and the cardiac gap junction protein CONNEXIN-43. Functional characteristics were determined by electrophysiology measurements of cardiac action potentials, and response of beating clusters to chronotropic drugs. The efficiency of cardiac differentiation was determined to be up to 70% as assessed by flow cytometry of cardiac markers, and a high number of cardiac cells per stem cell initially seeded was obtained.
Current results for optimizing our differentiation protocol, and for further improving the efficiency are presented and strategies to translate the method to various cell lines are discussed. Parallel work is concentrated on reducing production costs, for example, by introducing small molecules as differentiation factors, for developing scalable processes using stirred suspension vessels to generate functional cardiomyocytes.

W-2292

RAPID HEART DISSOCIATION AND SUBSEQUENT ALLOCATION OF PURIFIED HEART CELLS FOR CARDIAC TISSUE ENGINEERING

Manuel Kernbach, Anne Maria Wiencierz, Andreas Bosio, Dominik Eckardt, **Peter Christalla**
Miltenyi Biotec GmbH, Bergisch Gladbach, Germany

Engineered cardiac tissue offers the possibility to replace infarcted myocardium and to investigate heart development and cardiomyogenesis in a simplified in vitro model. It is generally accepted that tri-culture of cardiomyocytes (CMs), fibroblasts (Fibs) and endothelial cells (Endos) enhances functionality of engineered cardiac tissues in vitro and improves survival in vivo. However, one of the major challenges is the availability of pure heart cells to generate in vivo-like cardiac tissues in a dish. Utilizing an automated tissue dissociator (gentleMACS) we developed a rapid neonatal heart dissociation protocol enabling an efficient immunomagnetic enrichment of CMs, Fibs and Endos.
First, we established an enzyme mix optimal for the dissociation of neonatal mouse and rat hearts (P0-P3) by screening our enzyme library. Next, we optimized the dissociation by utilizing our gentleMACS technology resulting in a fast (1h), robust and automated heart dissociation protocol. Analysis of the dissociated heart cells showed: (i) high cell vitalities (>90%), (ii) high frequencies of α-actinin-positive CMs (60%; P2) and (iii) vimentin-positive non-CMs with a frequency of 40% (P2). In order to selectively enrich various cell-types from these heterogenous cell populations, we performed a cell-surface marker screen. We identified several candidates for the composition of antibody cocktails enabling selective enrichment of CMs, Fibs or Endos with purities of up to 97%. Cultured CMs showed spontaneous beating activity and the expression of sarcomeric proteins in a cross striated pattern. In summary, we established an automated protocol for the dissociation of neonatal hearts, enabling the subsequent immunomagnetic enrichment of CMs, Fibs and Endos which can readily be utilized to generate in vitro heart muscle models and surrogate tissue for myocardial repair.

Embryonic Stem Cell Pluripotency

CULTURE OF HUMAN ES AND IPS CELLS USING TESR™-E8™: A SIMPLIFIED AND LOW PROTEIN MAINTENANCE MEDIUM COMPATIBLE WITH EITHER BD MATRIGEL™ OR VITRONECTIN XF™

Erik B. Hadley, Alvin Ng, Heather Drew, Matthew Wong, Mandy Chan, Jessica Norberg, Melanie D. Kardel, Jennifer Antonchuk, Cindy Miller, Allen C. Eaves, Terry E. Thomas, Sharon A. Louis
STEMCELL Technologies Inc., Vancouver, BC, Canada

The media, protocols and culture systems used for human embryonic stem (ES) and induced pluripotent stem (iPS) cells under feeder-free conditions have undergone steady improvements since their widespread use was adopted during the last decade. A key contributor to this progress has been the defined, reproducible and feeder-free maintenance medium and culture conditions provided by commercially available mTeSR™1 (STEMCELL), which was developed based on publications from James Thomson's laboratory [Ludwig et al., 2006]. Further developments by the Thomson laboratory have demonstrated that it is possible to remove some extraneous additives and most of the protein content from the base mTeSR™1 formulation, resulting in a simplified medium known as E8 [Chen et al., 2011]. A commercially manufactured version of the E8 formulation, TeSR™-E8™ (STEMCELL), is now available as an alternative maintenance medium for human ES and iPS cell culture. The aim of this study was to test the robustness of new TeSR™-E8™ by assessing cell morphology, cell expansion and pluripotent marker expression in two ES (H1, H9) and three iPS (WLS-1C, WLS-4D1, A13700) cell lines cultured in TeSR™-E8™ in the presence of two different culture matrices: BD Matrigel™ and Vitronectin XF™ (Developed and manufactured by Primorigen Biosciences). To initiate TeSR™-E8™ cultures, cells routinely cultured in mTeSR™1 were dissociated into cell aggregates and then plated onto pre-coated plates containing TeSR™-E8™ medium. Cells were passaged every 5 - 7 days for up to 20 passages using an enzyme-free passaging protocol. Briefly, cells were dissociated using Gentle Cell Dissociation Reagent (STEMCELL) for either 6 - 8 minutes (BD Matrigel™) or 10 - 12 minutes (Vitronectin XF™). The dissociation reagent was removed and replaced with TeSR™-E8™ medium prior to detachment of cell aggregates by scraping. A key step in the passaging protocol was the generation of appropriately sized cell aggregates after harvest by controlling the mechanical dissociation steps prior to replating of the cells. We observed that colonies grown in TeSR™-E8™ had a more condensed and round morphology when grown on Vitronectin XF™ compared to colonies grown on BD Matrigel™, which were more diffuse and irregularly shaped. High cell expansion was achieved across the ES and iPS cell lines tested over the indicated number of passages (p) when using either BD Matrigel™ (H1: 21 ± 3.6 fold; 10p, H9: 36 ± 5; 10p, WLS-1C: 35 ± 5; 10p, WLS-4D1: 19 ± 3; 10p, A13700: 30 ± 4; 10p) or Vitronectin XF™ (H1: 28 ± 2 fold; 6p, H9: 33 ± 4; 8p, WLS-1C: 34 ± 4; 4p, WLS-4D1: 37 ± 7; 7p, A13700: 56 ± 20; 4p). Finally, high expression of pluripotent markers (SSEA3, TRA-1-81 and Oct4) was maintained in cells cultured in TeSR™-E8™ on both matrices. In conclusion, our findings demonstrated that TeSR™-E8™ is a robust maintenance medium for human ES and iPS cells, and is capable of maintaining high quality cell cultures in combination with either BD Matrigel™ or defined Vitronectin XF™.

MAINTENANCE OF PLURIPOTENT STEM CELLS CONTROLLED BY KLF5

Takuya Azami, Ken Matsumoto, Hyojung Jeon, Satoru Takahashi, Masatsugu Ema
Department of Anatomy and Embryology, University of Tsukuba, Tsukuba, Japan

Pluripotency is maintained by the core transcription factors, such as Oct4, Sox2, and Nanog. These transcription factors also have important roles in embryonic development and can reprogram somatic cells into iPS cells. Among the Yamanaka factors, Klf4 is dispensable for ES cells self-renewal and early embryo development. Klf4 together with Klf2 and Klf5 play redundant functions in ES cells. However, our previous study clearly indicated that Klf5 is indispensible for blastocyst development (Ema et al., 2008). Therefore, it is important to elucidate the molecular mechanism underlying these functions.
To understand the mechanism, we first addressed the precise phenotype of Klf5 KO embryos. By investigating the BrdU incorporation activity and lineage-marker expressions in Klf5 KO embryos at each early development stage, we show that cell cycle progression is impaired before the reduced cell number and lineage marker expression ap-

peared. These results suggest that there are common mechanisms in the regulation of cell-cycle between ES cells and embryo. To reveal the cell-cycle regulation mechanism by Klf, we amplified the cDNA from embryos and performed the microarray analysis. Then we found that FGFR signaling pathway related genes was hyperactivated in Klf5 KO embryos. Pharmacological inhibition for this pathway by specific inhibitor resulted in significant rescue for Klf5 KO phenotypes. Interestingly, Nanog positive pluripotent cells were emerged in ICM of Klf5 KO embryos after pharmacological inhibiton of FGFR signaling pathway. We examined whether Klf5 KO ES cells are derived from rescued blastocyst. We obtained 60 ES cell lines from 92 embryos, and remarkably, 7 lines of Klf5 KO ES cell were derived from rescued embryos. These results clearly shows that FGFR signaling pathway is hyperactivated in Klf5 KO embryos. Since our previous study revealed that Klf5 KO ES cells showed upregulation of Fgf5 expression, we examined whether FGFR signaling pathway is hyperactivated in Klf5 KO ES cells. Compared to WT ES cells, Klf5 KO ES cells exhibited elevated levels of the phosphorylation of ERK1/2. Moreover, when Klf5 KO ES cells were cultured in the presence of Mek inhibitor or Fgfr inhibitor, defective proliferation was partially, but significantly rescued. These results suggest that Klf5 suppress FGFR signaling pathway in the embryo and ES cells, and act as a safeguard for the maintenance of pluripotent stem cells.

W-2297

MAINTENANCE OF HUMAN EMBRYONIC STEM CELLS IN FEEDER AND bFGF FREE CULTURE SYSTEM USING CONDITIONED MEDIA FROM IMMORTALIZED HUMAN FORESKIN FIBROBLAST CELLS

Sujata Mohanty[1], Pooja Teotia[1], Balram Airan[2]

[A]Stem Cell Facility, [B]Department of Cardiothoracic and vascular Surgery, [1]AIIMS, New Delhi, New Delhi, India

Mouse and Human feeder cells have important role in the maintenance of Human Embryonic Stem Cells (hESCs) in undifferentiated state as well as for their propagation. However, use of feeder cells in hESC culture limits their future therapeutic applications. There have been reports of using conditioned media (CM) derived from mouse or human feeder cells for the propagation of hESC in feeder free culture. These CM contain certain factors required for maintaining ESC in undifferentiated and pluripotent state. Recently, TGF-β and IGF-II have been shown to be important for the maintenance of hESC.

Feki et. al. reported the establishment of stably Immortalized Human Foreskin Fibroblasts (I-HFF) cells to be used as feeders for culturing hESC and iPSC. These cell lines have been stably transduced with secreted form of bFGF. This study aims to (i) quantiate the secretion of TGF- β and IGF-II by I-HFF feeder, (ii) explore the potential of CM derived from I-HFF feeder to support ES cells in feeder free system, (iii) minimize the dose of an exogenous bFGF required to sustain hESC in feeder free system.

The secretion of TGF- β and IGF-II from the mitomycin-C treated I-HFF supplemented with various exogenous bFGF concentration (0, 2, 5 and 10ng/ml) was assessed by ELISA. The KIND -1 hES cell lines were gradually adapted to grow in feeder free system on geltrex coated culture dishes using CM at varying concentration of exogenous bFGF supplementation (0,2,5 and 10ng/ml). The KIND-1 cell line cultured in hESC media with 10 ng/ml bFGF was taken as positive control. The hESC line grown in feeder free culture with CM was assessed on the basis of morphology, expression of pluripotent makers at 1st, 3rd, 5th and 10th passage by Immunoflorescence and flow cytometry. Any karyotypic abnormalities were also assessed at 20th passage.

ELISA results confirmed that the level of both TGF- β and IGF-II secretion was comparable at all bFGF treated group versus no exogenous bFGF added. The cells cultured in the CM in the feeder free conditions even after 20 passages, showed typical hESC morphology and expression of pluripotency-related proteins, SSEA-4, TRA-1-60, OCT4, alkaline phosphatase and normal karyotypes in all groups compared to positive control. Flow cytometric analysis for TRA1-60 and SSEA-4 surface marker expression shows the increasing trend but the difference was negligible among different groups. (From 0-, 2, 5,10ng/ml and positive control TRA1-60: 0- 75.6% + 3.86, 2- 76.87% + 5.64, 5- 77.28% + 5.21, 10- 78.1% + 5.83 and 81.6% + 3.53, SSEA-4: 0- 81.47%+4.27, 2- 82.9%+3.86, 5- 82.73%+3.80, 10- 84.07%+5.72 and 82.73%+3.80 respectively). There was no difference in the expression of pluripotency-related genes (OCT4, SOX-2, c-MYC, Klf-4 and NANOG) in test groups as compared to positive control as reveled by semi quantitative RT-PCR.

In conclusion, (i) the I-HFF CM secrete TGF- β and IGF-II without addition of exogenous bFGF, (ii) addition of various dose of bFGF did not scale up the secretion of TGF- β and IGF-II, suggesting that the endogenous bFGF secretion is sufficent to maintain auto regulation of TGF- β and IGF-II, (iii) the I-HFF CM is able to support and maintain hESC propagation and pluripotency without addition of exogenous bFGF. Thus the CM is an alternative to achieve cost effective and feeder free culture system.
Acknowledgment: We thank Prof. Anis Feki, Geneva University, Switzerland and Dr. Deepa Bhartia, National Institute for Research in Reproductive Health, India for providing I-HFF and KIND-1 hESC lines.

ACTIVATION OF DNA DAMAGE RESPONSE DOES NOT INDUCE G1/S CHECKPOINT IN MOUSE EMBRYONIC STEM CELLS

Irina I. Suvorova, Valery A. Pospelov
Laboratory of Molecular Mechanisms of Cell Differentiation, Institute of Cytology, St-Petersburg, Russian Federation

The DNA damage response (DDR) integrates different signaling pathways activated by DNA-damaging agents and is primarily coordinated by ATM and ATR kinases, initiating a cascade of phosphorylation events, eventually resulting in cell cycle checkpoint activation, DNA repair and apoptosis. Mouse embryonic stem cells (mESCs) are characterized by high proliferation activity and do not undergo G1/S checkpoint upon DNA-damage. In this study we examined the ATM/ATR signaling pathway to analyze DNA repair capacity of mESCs and checked the functionality of the p53-p21/Waf1 pathway that provides G1/S checkpoint in somatic cells.
According to flow cytometry analysis, inhibitors of ATM, ATR, and Chk1 but not Chk2 affect cell cycle both in control and irradiated (IR) mESCs. ATM+ATR inhibitor caused accumulation of G1-phase cells and decreased the amount of S phase cells. Treatment of mESCs with ATM/ATR inhibitor enhanced the effect of IR on cell cycle: it further reduced the number of cells in S phase and caused the accumulation of cells in G2/M. Inhibition of ATM kinase caused a weaker effect. We next suppressed ATM/ATR targets, Chk1 and Chk2, and found that inhibition of Chk1 in IR-treated mESCs caused accumulation of mESCs in G1 phase and decrease of G2 cells.
MTT test revealed the ATM, ATR, Chk1, Chk2 contribution to survival of mESCs after DNA damage. Treatment with ATM/ATR inhibitor increased cell death in control and irradiated mESCs, whereas ATM inhibitor caused no effect. Again, inhibition of Chk1 in IR-treated cells caused an effect compared with ATM/ATR inhibitor + IR. Chk2 inhibitor had no effect on the survival of mESCs.
Immunofluorescent confocal microscopy and western blotting for phospho-ATM (Ser-1981) and phospho-ATR (ser-428) showed that in mESCs ATM/ATR kinases are phosphorylated and accumulated in the nuclei after DNA damage. We also showed that irradiated mESCs form H2AX foci that co-localize with 53BP1 protein and Rad51. In control, non-irradiated mESCs, uninduced γH2AX foci do not contain 53BP1.
By using antibodies against phospho-p53 (Ser-15) and acetyl-p53 (Lys-379), we showed that IR or H_2O_2 induced the p53 stabilization and its transcriptional activity. However, although p21 mRNA is clearly up-regulated after DNA damage, p21 protein is not detectable. To investigate the mechanisms of negative regulation of p21, we used proteasome inhibitors (lactacystin, MG132) and inhibitor of histone-deacetylases sodium butyrate (NaBut). Both NaBut and proteasome inhibitors cause the accumulation of p21Waf1 implying the regulation of p21Waf1 as at the level of gene regulation as at the level of protein stability.
The findings suggest that despite the absence of a functional G1 checkpoint caused by dysfunction p53/p21Waf1 pathway in mESC, the ATM/ATR signaling is activated with comcomitant activation of downstream targets that is a necessary step to initiate the process of DNA repair.

MOLECULAR MECHANISMS FOR BUFFERING PLURIPOTENCY IN EMBRYONIC STEM CELLS

Dmitri Papatsenko[1], Ihor R. Lemischka[2], Henia Darr[2]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States, [B]Department of Developmental & Regenerative Biology, [1]Icahn School of Medicine at Mount Sinai, New York, NY, United States

Until recently, knowledge regarding hierarchical organization of pluripotency network in mESC was relatively fuzzy. Most studies assume the top (or central) position of the Oct4-Sox2-Nanog circuit, while the exact connections between the factors remain unknown.
Based on the analysis of knock-down studies of the core pluripotency factors (differentiation experiments) we proposed a new view of the network relevant to pluripotency, in which Oct4 occupies the top position in the hierarchy and Nanog, Esrrb, Sox2 occupy lower level. The hierarchical analysis revealed a new network motif, incoherent feed-forward loop Oct4-Nanog-Sall4, which appears to play an important role in pluripotency.
Recently published data (Cell. 2012, 150(6):1209-22) suggested presence of regulatory link Sall4 -> Oct4, thus adding a feedback connection to the identified Oct4-Nanog-Sall4 network motif.
Quantitative exploration of solutions for the identified network connecting the three genes, along with new hierarchical structure of the pluripotency network suggested a molecular mechanism for safeguarding or buffering of pluripotency. Available experimental data supports the central position of the Oct4-Nanog-Sall4 in the pluripotency network and the proposed buffering role of the identified network motif.

HETEROGENEOUS NUCLEAR RIBONUCLEOPROTEIN A2/B1 REGULATES THE SELF-RENEWAL AND PLURIPOTENCY OF HUMAN EMBRYONIC STEM CELLS VIA THE CONTROL OF THE G1/S TRANSITION

Hong Seo Choi[1], HYUN MIN LEE[1], YOUNG-JOO JANG[2], CHEORL-HO KIM[3], CHUN JEIH RYU[1]
[1]Sejong unversity, Seoul, Korea, Republic of, [2]Dankook unversity, Cheonan, Korea, Republic of, [3]Sungkyunkwan university, Suwon, Korea, Republic of

Self-renewal and pluripotency of human embryonic stem
cells (hESCs) are a complex biological process for maintaining hESC stemness.
However, the molecular mechanisms underlying these special properties of hESCs
are not fully understood. Heterogeneous nuclear ribonucleoprotein A2/B1 (hnRNP
A2/B1) is a multifunctional RNA-binding protein whose expression is related to cell proliferation and carcinogenesis. In this
study, we found that hnRNP A2/B1 expression was localized to undifferentiated
hESCs, and decreased upon differentiation of hESCs. hnRNP A2/B1 knockdown
reduced the number of alkaline phosphatase-positive colonies in hESCs and led
to a decrease in the expression of pluripotency-associated transcription
factors OCT4, NANOG and SOX2, indicating that hnRNP A2/B1 is essential for hESC
self-renewal and pluripotency. hnRNP A2/B1 knockdown increased the expression
of gene markers associated with the early development of three germ layers, and
promoted the process of epithelial-mesenchymal transition, suggesting that
hnRNP A2/B1 is required for maintaining the undifferentiated and epithelial
phenotypes of hESCs. hnRNP A2/B1 knockdown inhibited hESC proliferation and
induced cell cycle arrest in the G0/G1 phase before differentiation via
degradation of cyclin D1, cyclin E, and Cdc25A. hnRNP A2/B1 knockdown increased
p27 expression and induced phosphorylation of p53 and Chk1, suggesting that
hnRNP A2/B1 also regulates the G1/S transition of hESC cell cycle through the
control of p27 expression and p53 and Chk1 activity. Analysis of signaling
molecules further revealed that hnRNP A2/B1 regulated hESC proliferation in a
PI3K/Akt-dependent manner. These
findings provide for the first time mechanistic insights into how hnRNP A2/B1
regulates hESC self-renewal and pluripotency.

TCF-3 AND JNK IN THE GLUCOSE MEDIATED CONTROL OF PLURIPOTENCY AND DIFFERENTIATION IN MURINE ESCS

Darcie L. McClelland Descalzo[1], Tiffany Satoorian[1], Devon D. Ehnes-Zepeda[1], Roger J. Davis[2], Bradley J. Merrill[3], Nicole I. zur Nieden[1]

[1]Cell Biology and Neuroscience, University of California, Riverside, Riverside, CA, United States, [2]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, United States, [3]Biochemistry and Molecular Genetics, University of Illinois at Chicago, Chicago, IL, United States

Current studies estimate that 10-18% of women of reproductive age have diabetes or a related disorder. This is alarming considering that 7-13% of diabetic mothers give birth to a child with a major structural birth defect. Though recent advances in insulin therapy have significantly curtailed miscarriages due to hyperglycemia during pregnancy, glucose induced defects suffered by the fetus during the pre-implantation stage of development still pose a huge problem to modern medicine. While scientists have isolated the elevated maternal blood glucose levels as the primary cause of fetal malformations, the mechanisms by which glucose stress induces birth defects still remain to be elucidated.

Our lab utilizes mouse embryonic stem cells as a model for pre-implantation embryos. By exposing cells to different glucose concentrations and tracking changes in characteristics related to the pluripotent state, we aim to gain insights into what may be happening to human embryos when the basic plan for life is laid out. In addition, we examine the role of β-catenin (CatnB) to determine how its levels and localization adapt to fluctuations in glucose levels. Recently, we have been examining the contributions of TCF-1, TCF-3, and JNK to CatnB transcriptional activity and thus embryo development in different glucose concentrations. When wildtype cells are exposed to hyperglycemic conditions, they lose the ability to remain pluripotent. In addition, cells increase nuclear TCF-3 protein and decrease nuclear TCF-1 protein. Because TCF-3 has previously been shown to inhibit pluripotency factors and is increased in response to glucose, we hypothesized that it may contribute to the phenotypic changes associated with hyperglycemia.

Cells with a genetic deletion of TCF-3 maintain pluripotency and show increased mRNA levels of Oct-4 and Nanog in all glucose concentrations when compared to wildtype cells. From this data, we determined that TCF-3 may affect the switch from pluripotency to differentiation in hyperglycemia. In addition, we performed sequential Chromatin Immunoprecipitation and found that the amount of TCF-3 bound to the promoters of Oct4 and Nanog is increased upon glucose challenge while the amount of TCF-1/CatnB bound to these promoters is simultaneously decreased. This data suggests that TCF-1/CatnB and TCF-3 may compete for binding on target gene promoters and that glucose may impact the ratio of binding, ultimately influencing the pluripotency state of the cells.

Upstream, TCF-3 nuclear shuttling may be regulated by c-jun NH(2)-terminal kinase (JNK). Thus, JNK may indirectly contribute to the phenotypic switch to differentiation through increasing nuclear TCF-3. Indeed, JNK activation increases with glucose levels and this correlates with an increase in nuclear TCF-3 protein. When cells were treated with a JNK inhibitor, protein levels of TCF3 were decreased and levels of Nanog, which is known to be inhibited by TCF-3, were increased. Currently, we are examining stem cell fate in cells with a genetic deletion of JNK to determine whether its absence will deplete nuclear TCF-3 and lead to increased pluripotency. Taken together, these results will bring us closer to understanding the mechanisms behind phenotypic changes in unspecified cells in the early embryo. Once we can fully elucidate this mechanism, it will provide valuable knowledge for future studies on preventing birth defects in children born to diabetic mothers.

DOWNREGULATION OF OCT-4 INHIBITS PROLIFERATION OF ES CELLS BY INDUCING G1 CELL CYCLE ARREST

Jungwoon Lee, Inyoung Kang, **Jungho Kim**
Sogang Univ, Seoul, Korea, Republic of

Mouse and human embryonic stem (ES) cells display unusual proliferative properties and can produce pluripotent stem cells indefinitely. Both processes might be important for maintaining the stemness of ES cells; however, little is known about how the cell cycle fate is regulated in ES cells. Oct-4, a master switch of pluripotency, plays an important role in maintaining the pluripotent state of embryonic stem cells and may prevent the expression of genes activated during differentiation. Using ZHBTc4 ES cells, we have investigated the effect of Oct-4 on ES cell cycle control, and we found that Oct-4 down-regulation in ES cells inhibits proliferation by blocking cell-cycle progression in G0/G1. Deletion analysis of the functional domains of Oct-4 indicates that the overall integrity of the Oct-4 functional domains is important for the stimulation of S-phase entry. We also show here that the p21 gene is a target for Oct-4 repression. Furthermore, p21 protein levels were repressed by Oct-4 and were induced by the down-regulation of Oct-4 in ZHBTc4 ES cells. Therefore, the down-regulation of p21 by Oct-4 may contribute to the maintenance of ES cell proliferation.

CONVERSION OF THE PLURIPOTENT STATE IN NON-HUMAN PRIMATE ES CELLS

Seiji Shiozawa[1], Junko Okahara[2], Hirotaka James Okano[3], Toshiaki Noce[1], Erika Sasaki[1], Hideyuki Okano[1]
[1]Keio University School of Medicine, Tokyo, Japan, [2]Central Institute for Experimental Animals, Kanagawa, Japan, [3]Jikei University School of Medicine, Tokyo, Japan

Although both primate and mouse embryonic stem (ES) cells are pluripotent stem cell lines derived from inner cell mass (ICM) of blastocyst stage embryos, they show distinct characteristics. Currently, primate ES cells have been considered as counterpart of mouse epiblast stem cells (EpiSCs) because of their close resemblance. The pluripotent state of mouse EpiSCs is termed primed state to distinguish from naïve state pluripotency of mouse ES cells. Primate ES cells have been regarded as primed state pluripotent stem cells and the naïve state pluripotent stem cells in primate has not been established so far. Using ES cells of common marmoset, a small non-human primate, we have carried out the conversion from primed state to naïve state pluripotency.
Doxycycline-inducible (DOX-inducible) reprogramming factors transgenes were introduced into common marmoset ES cells by piggyBac transposon transgenesis, and the cells were cultured in a medium containing LIF, Dox and cocktail of small molecules. Resulting cells formed mouse ES cell-like dome-shaped colonies and maintained expression of pluripotency markers. Furthermore, these cells showed similar gene expression pattern to mouse ES cells and ICM cells of marmoset blastocyst. These phenotypes were lost by addition of JAK inhibitor to culture, suggesting maintenance of this pluripotent state require LIF/STAT3 signal.
These properties of the common marmoset ES cells closely resembled to mouse ES cell, suggesting that the cells acquired naïve state pluripotency. To further confirm naïve pluripotency of the cells, we are currently carrying out chimera formation assay.

W-2307

HESC EXPANSION AND STEMNESS ARE INDEPENDENT OF GJIC THROUGH CX43 BETWEEN HESC AND FEEDER CELLS

Jin-Su Kim[1], Seung-Twang Hwang[1], Daekee Kwon[1], Dong-Ryul Lee[1], Won Kim[2], Myung-Kwan Han[2], Soo-Hong Lee[1]
[1]CHA Univ, Seoul, Korea, Republic of, [2]Chonbuk National Univ, Gyeonggi-do, Korea, Republic of

Human embryonic stem cells (hESCs) are a promising and powerful source of cells for applications in regenerative medicine, tissue engineering, cell-based therapies, and drug discovery. Many researchers have employed conventional culture techniques using feeder cells to expand hESCs in significant numbers, although feeder-free culture techniques have recently been developed. In regard to stem cell expansion, gap junctional intercellular communication (GJIC) is thought to play an important role in hESC survival and differentiation. Indeed, it has been reported that hESC-hESC communication through connexin 43 (Cx43, one of the major gap junctional proteins) is crucial for the maintenance of hESC stemness during expansion. However, the role of GJIC between hESCs and feeder cells is unclear and has not yet been reported. This study therefore examined

whether a direct Cx43-mediated interaction between hESCs and human adipose-derived stem cells (hASCs) influences the maintenance of hESC stemness. Over 10 passages, hESCs cultured on a layer of Cx43-downregulated hASC feeder cells showed normal morphology, proliferation (colony growth), and stemness, as assessed by alkaline phosphatase (AP), Oct4, Sox2, and Nanog expression. These results demonstrate that Cx43-mediated GJIC between hESCs and hASC feeder cells is not an important factor for the conservation of hESC stemness and expansion.

W-2308

A SERUM-FREE AND FEEDER-FREE DEFINED MEDIUM THAT ENABLES WEEKEND-FREE CULTURE OF UNDIFFERENTIATED HUMAN PLURIPOTENT STEM CELLS

Min Lu[1], Naomi Guyette[1], Boris Greber[2], Vi Chu[1]

[1]Bioscience Division, Stem Cell Group, EMD Millipore, Temecula, CA, United States, [2]Max Planck Institute for Molecular Biomedicine, Münster, Germany

Current media formulations used to culture undifferentiated pluripotent human ES and induced pluripotent stem (iPS) cells require media replenishment every day and at least 1 media exchange on the weekend. The costs in media reagents and human resources become prohibitively expensive as increasing numbers of core labs and consortiums are focused on generating diseased human iPS cell models. We have identified 11 essential components in a serum-free and feeder-free medium that enables weekend-free culture of undifferentiated human pluripotent stem cells and allows for media exchanges every other day without compromising the morphology or long term functionality of pluripotent stem cells. These 11 components include HSA, lowered FGF (10% of E8), TGFb1 (25% of E8) and Activin A concentrations and small molecule inhibitors to suppress spontaneous differentiation.
For the study, H9 human ES cells and 2 different clones of transgene-free human iPSCs were used. Transgene-free human iPSCs were generated by a Cre-excisable polycistronic lentiviral vector expressing the “stem cell cassette” (STEMCCA) comprised of all four transcription factors (OKSM) followed by exposure of the full reprogrammed iPSC to cell permeable TAT-Cre recombinant protein. All three pluripotent cell lines whether originally cultured in feeder-based or feeder-free cultures could be easily and directly adapted to the 11-component medium without noticeable differences in cell vitality and cell health. Pluripotent cells maintained in the 11 component medium (>20 passages) expressed high levels (>90%) of pluripotency markers including SSEA4, OCT4, TRA-1-60 and TRA-1-81; possessed normal karyotype; and were capable of differentiating into derivatives of all three germ layers in vitro and in vivo.
Remarkably, H9 cells remained undifferentiated and exhibited minimal signs of spontaneous differentiation and could furthermore be serially passaged with a minimal 1 day per week media exchange. While a 25-33% reduction in the number of attached colonies was observed, the colonies remained undifferentiated and proliferated at a similar apparent rate (i.e. 5-6 days between passages) to controlled cultures of regular media exchanges. These unexpected results led us to determine the long-term effects of a more moderate feeding regiment of every other day combined with an absence of weekend media replacement. Pluripotent cells maintained in this moderate feeding regiment exhibited high cell health with minimal spontaneous differentiation; expressed high levels of pluripotency markers and possessed a normal karyotype. Current efforts are aimed at identifying the critical component(s) that confer this advantage and whether nutrient-sensitive signaling pathways that regulate energy metabolism may be involved.

W-2311

THE RABBIT PRE IMPLANTATION EMBRYO AS A PARADIGM TO EXPLORE NAIVE EMBRYONIC STEM CELL DERIVATION IN NON RODENT SPECIES

Pierre OSTEIL[1], Yann TAPPONNIER[1], Anaïs MOULIN[1], Thierry JOLY[2], Pierre SAVATIER[1], Marielle AFANASSIEFF[1]

[1]Stem cell and Brain Research Institute, INSERM U846, INRA USC1361, BRON, France, [2]VetAgroSup, UPSP ICE, ISARA-Lyon, Lyon, France

The scarcity of pre-implantation embryos in human is a major limitation to the improvement of embryonic stem cell (ESC) derivation in non-rodent species. Rabbit is a good alternative as it can produce up to 30 embryos per super-ovulated females. Moreover, all rabbit ESC line produced so far showed the characteristics of primed pluripotency like human ESCs. In this work, we investigated the conditions suitable for the generation of naïve ESCs in rabbits. A first experiment aimed to study the effect of the pharmacological inhibitor of MEK signaling, PD0325901, on embryo development and ESC line derivation. We collected 576 eight-cell stage embryos, of which 317 were cultured in the presence of MEK inhibitor until they reached the early blastocyst stage. No difference in the rate and quality of embryo development between MEK inhibitor-treated and control embryos was observed. ICMs were isolated by immunosurgery and plated onto gelatin- or fibronectin-coated dishes in various media (DMEM/F12 + 20% KOSR, N2B27) supplemented with GSK3 inhibitor (CHIR99021), MEK inhibitor, and LIF (2i/LIF), or not. 80% of the ICMs plated, but none could be expanded beyond passage 2. We concluded that inhibition of MEK signaling fails to prevent spontaneous differentiation of pluripotent stem cells in rabbit. A second experiment aimed to study the effect of LIF on ESC line derivation. We collected 262 ICMs, which were plated onto growth-inactivated mouse embryonic fibroblasts in DMEM/F12 supplemented with 20% KOSR (72), 20% KOSR + LIF (90), or 10% KOSR + 10% FCS + LIF (80). No outgrowth cultured in media lacking LIF could be expanded beyond passage 4. By contrast, 7 ESC lines were derived from outgrowths cultured and expanded in the presence of LIF, 2 in 20% KOSR + LIF, and 5 in 10% KOSR + 10% FCS + LIF. Two lines, designated rbES-LIF1 and rbES-LIF2, were expanded by gentle dissociation with collagenase until passage 40, and showed a normal karyotype. RbES-LIF1 and rbES-LIF2 displayed the cardinal features of pluripotent stem cells, i.e. expression of pluripotency markers, differentiation into derivatives of the 3 germ layers, and teratoma formation. However, they could not be cultured onto gelatin-coated dishes, they did not express markers associated with naïve pluripotency in rodents, and they did not survive in 2i/LIF medium. We concluded that LIF facilitates the derivation of ESCs but does not support naïve pluripotency in rabbits. When rbES-LIF1 and rbES-LIF2 cells were propagated for 20 passages in 10% KOSR + 10% FCS + LIF, and were enzymatically dissociated with Accutase into single cell suspensions, they acquired chromosomal abnormalities (43XX; 45XY). The same observation was made with the 5 freshly derived ESC lines in 10% KOSR + 10% FCS + LIF with Accutase, of which 3 displayed abnormal chromosome numbers. We concluded that LIF-dependent rabbit ESCs cannot be propagated under stringent conditions without frequent chromosomal rearrangement-based adaptation.

W-2312

INCREASED DLK-1 EXPRESSION IN HUMAN EMBRYONIC STEM CELLS, HAS A PUTATIVE ROLE IN THE MAINTAINANCE OF PLURIPOTENCY.

David J. Harley, Dylan Stavish, Paul J. Gokhale, Peter W. Andrews
Department of Biomedical Science, University of Sheffield, Sheffield, United Kingdom

Delta-like homolog 1 (DLK-1) is a trans-membrane domain cell signalling protein that interacts with NOTCH. It is known to be up-regulated when comparing normal and culture adapted human embryonic stem (hES) cells. Culture adapted hES cells exhibit an increased capacity to self renew, and by profiling normal and adapted against one another we have highlighted genes important for hES maintenance. DLK-1 has been indicated in many tissue specific areas and associated cancerous phenotypes but the mechanisms by which signalling occurs is not fully characterised. Moreover it appears that DLK-1 can act in an equivalent manner to NOTCH and its counterparts, via cell-cell interactions, peptide cleaving micro-environmental effects and as a receptor itself, with each of these designating a specific downstream effect. NOTCH signalling is known to regulate the hierarchical differentiation in many cell populations within the adult and is essential for normal development.
Utilizing normal and adapted hES cells and their malignant counterparts, human embryonal carcinoma (hEC) cells, we investigated the role of DLK-1 in the adaptation of hES cells and its links with other pathways at the gene expression and proteomic level. This has highlighted a correlation between the ability of cells to self renew and an increase in DLK-1 expression. Furthermore, markers associated with pluripotency, differentiation and more specifically those involved in the NOTCH signalling pathway have also been identified. In addition we have explored the effects of DLK-1 signalling in the hES micro-environment and the mechanisms by which it increases the self-renewal and pluripotency of hES lines.

Knockdown of DLK-1 in the adapted hES cells triggers the onset of differentiation at an earlier stage in colony development, measured by the down regulation of pluripotency markers OCT-4, NANOG and SSEA3. NOTCH1 signalling is elevated on induction of the knockdown of DLK-1 and has been shown to induce the differentiation of hES cells leading to a reduction in self renewal and upregulation of markers of differentiation. Conversely hES cells over-expressing DLK-1 exhibit an increase in proliferation.

W-2313

SELF ASSEMBLING SCAFFOLD SUPPORTS PLURIPOTENT GROWTH OF EMBRYONIC STEM CELLS

Christina McKee, Ferman Chavez, Rasul Chaudhry
Oakland University, Rochester, MI, United States

Embryonic stem cells (ESCs) have unlimited self-renewal and differentiation potential. In vitro culturing of ESCs is laborious, technically challenging, and often leads to the loss of cell lines due to differentiation. To address these problems, considerable attention has been focused on devising culture conditions that mimics in vivo stem cell microenvironments. We hypothesized that three dimensional (3D) culture conditions may be better than routinely used 2D cultures for the maintenance and expansion of ESCs. The objective of this study was to test biodegradable nanomaterials to produce a 3D culture matrix capable of long-term propagation of pluripotent ESCs. To achieve 3D culture conditions, self-assembling scaffolds were developed by mixing thiol-functionalized dextran (Dex-SH) and poly (ethylene glycol) tetra-acrylate (PEG-4-Acr) via Michael addition reaction. Testing of various parameters including the components of scaffold and encapsulation of ESCs led to the development of 3D culture conditions that promoted the self-renewal and pluripotent growth of ESCs for an extended period of time. The scaffold grown cells exhibited typical morphological and biochemical characteristics similar to ESCs grown in 2D culture. Quantitative RT-PCR analysis showed that 3D cultured ESCs expressed a pluripotent gene, Klf4 at a level comparable to the cells grown in traditional 2D culture. Interestingly however, two prominent pluripotent genes, Oct-4 and Nanog, were expressed up to 3 fold higher levels and remained high until the scaffolds started to degrade after 10 to 40 days. 3D scaffold grown ESCs maintained their pluripotency as they readily differentiated into adipogenic, myogenic, neural, osteogenic and chondrogenic cell lineages even after prolonged 3D culture. Overall, the self-assembling scaffold provided the necessary support and maintained undifferentiated growth of ESCs for several weeks without passaging. Our findings provide a reliable, reproducible, cost effective, and robust culturing system that should lead to increased applications of ESCs for understanding basic development and differentiation mechanisms, tissue engineering and cell therapy.

W-2314

HUMAN TUBE MESENCHYMAL STROMAL CELLS AS FEEDER-LAYERS FOR HUMAN EMBRYONIC STEM CELLS

Mayra Pelatti[1], Mariane Secco[1], Carlos Czeresnia[2], Paulo Perin[3], Tatiana Jazedje[4], Mayana Zatz[1]
[1]Institute of Bioscience, University of São Paulo, São Paulo, Brazil, [2]Célula Mater, São Paulo, Brazil, [3]CEERH Specialized Center for Human Reproduction, São Paulo, Brazil, [4]EPM UNIFESP, Federal University of São Paulo, São Paulo, Brazil

Cultivation of Human Embryonic Stem Cells (heSCs) requires feeder-layers or conditioned culture media. One of the main problems to circumvent aiming the potential therapeutic use of heSCs is animal contaminants in the culture media or the co-cultivation with animal cells. Among the various possible available feeder-layers, the Murine Embryonic Fibroblast (MEF) is still the most used, followed by fibroblasts from human skin. Aiming to test a xenofree heSCs culture method and trying to mimic the human embryo environment we have evaluated whether human tube Mesenchymal Stromal Cells (htMSCs), which are closely associated to the human embryo in early stage of development, provide a better support for heSCs growth, when compared to MEF and fibroblasts from human skin. For this study, three htMSCs lineages, which were characterized by cytometry and their differentiation potential in vitro were evaluated. Afterwards, the three htMSC lineages were used as feeder-layers for heSCs (kindly donated

by Douglas Melton) culture. As control feeder-layers, MEF and fibroblasts from human skin were used in the course of each experiment and all the experiments were performed in six well culture dishes.
Twenty four hours after the culture establishment (feeder-layers with heSCs), culture media was collected from each dish well and the expression of b-FGF (basic-Fibroblast Growth Factor) and TGF-β (Transforming Growth Factor) was analyzed by ELISA. Expression of signaling molecules WNT2, WNT4 and WNT8b in the heSCs cultures was analyzed by Western blot, and the expression of specific embryonic markers (Oct-4, Nanog, SSEA-3, SSEA-4, TRA-1-60, TRA-1-81 and KLF4) was confirmed by immunofluorescence and RT-PCR. Compared with MEF, htMSC feeder-layers cultures produced more heSCs colonies as well as a larger number of heSC per colony. Compared with human skin fibroblasts, htMSC feeder-layers produced heSCs colonies with more homogenous morphology (more undifferentiated colonies) and with a larger diameter, although the number of heSCs per colony was similar. The amount of b-FGF secreted by htMSCS was higher than the b-FGF released by the MEF twenty four hour after the heSCs culture establishment but the TGF- β secreted by htMSCs and MEF were similar. All the heSCs grown on htMSCs expressed WNT2, WNT4, WNT8b and all the specific embryonic markers tested, as expected. Thus, these results show that the use of htMSCs as feeder-layer represent an efficient xenofree method for heSCs cultivation.

W-2316

COMBINATORIAL SCREENING OF GELATIN NANOFIBERS AS CELLULAR SCAFFOLDS TO EXPAND HPSCS FOR LONG-TERM PERIOD

Li Liu, Ken-ichiro Kamei, Yong Chen
iCeMS, Kyoto University, Kyoto, Japan

Human pluripotent stem cells (hPSCs), such as embryonic and induced pluripotent stem cells (hESCs and hiPSCs), hold a promise for applications in cell-based therapy, tissue engineering, drug screening/discovery and regenerative medicine, since hPSCs have their unique characteristics, such as unlimited self-renewal capability under proper conditions and differentiation capability into any kind of cells in a human body. Recently, there are some efforts to develop new hPSC culture substrates, such as recombinant proteins, synthetic polymers and synthetic peptides, however, they require huge cost and labor intensiveness for preparation. Thus, it necessitates establishing the new substrates for hPSC expansion for long-term periods in a robust fashion.
Recently, nanofiber technology has attracted many researchers due to its application in fundamental cell biology as well as tissue engineering. In comparison with a conventional flat substrate, a nanofiberous substrate allows controlling the bulk-porosity, the surface texture and the three-dimensional (3D) surface topology for cell adhesion at a nanometer scale, altering focal-adhesion signaling cascades and consequently, the stem cell fate decision. During the past three years, we have successfully developed a nanofibres substrate as cellular scaffolds for expansion of mouse embryonic stem cells.
Here, we developed a new technology of gelatin electrospun nanofibers as a cellular scaffold for hPSCs long-term culture. We established a combinatorial library to vary density, crosslink conditions and gelatin molecular weight to screen the optimal conditions of fabricating nanofibers. Our results show that standardized gelatin nanofibers could support self-renewal for over 20 passages. However, hPSC couldn't passage on a gelatin-coated and crosslink treated flat substrate. In addition, we evaluated the pluripotent status of hPSCs cultured on gelatin nanofibers by immunocytochemistry, flow cytometry, RT-PCR, embryoid and teratoma formation and fluorescent in situ hybridization assay. According to such multiple angles of evaluation, we concluded that the gelatin nanofibers were able to serve as a cellular scaffold for expanding hPSCs while maintaining their pluripotent status and normal karyotype even after long-term culture. Finally, in order to understand how extrinsic 3D topological nanofibres influenced intrinsic cues during hPSC self-renewal, qPCR was carried out for all members of the integrin family. We found that gelatin flat-coated substrate and gelatin-nanofiber substrate were differed in the expression levels in some integrin members.
In the future, our goal is to develop a three-dimensional architecture of a cellular scaffold for cell transplantation therapies.

CO-REGULATION OF PLURIPOTENCY AND ENHANCED GENETIC INTEGRITY AT THE GENOMIC LEVEL

Daniel Cooper[1], Christi Walter[2], John R. McCarrey[1]

[1]Biology, The University of Texas at San Antonio, San Antonio, TX, United States, [2]Biology, University of Texas Health Science Center San Antonio, San Antonio, TX, United States

Pluripotent stem cells, including embryonic stem cells (ESCs) and induced pluripotent stem cells (iPSCs), have been reported to carry fewer genetic abnormalities than differentiated cells. Cells often deal with gross genetic aberrations such as polyploidy or aneuploidy retrospectively by programmed cell death, but for point mutations prospective avoidance must be achieved by DNA repair mechanisms. To characterize the mechanisms involved in the maintenance of enhanced genetic integrity in pluripotent stem cells, we have mined 18 previously published transcriptome and 5 cistrome databases describing gene expression and transcription factor binding in mouse and human ESCs, iPSCs and differentiated cells (fibroblasts). We observed significant up-regulation of DNA repair genes in both human and mouse ESCs and iPSCs relative to differentiated fibroblasts with very similar patterns of DNA repair gene expression in ESCs and iPSCs within each species based on expression data that was common to at least 50% of databases examined for each cell type. Functional analysis of these differentially expressed DNA repair genes by Ingenuity Pathway Analysis (IPA) revealed that mismatch repair and double-strand break repair by homologous recombination are the two most up-regulated repair pathways in pluripotent cells. Human and mouse pluripotent cells also showed significant differential expression of cell death genes compared to fibroblasts, but in contrast to DNA repair gene expression patterns, this included similar numbers of up- and down-regulated genes in the pluripotent cell types. However, upon further analysis of the cell death genes differentially expressed in pluripotent cells using IPA, we found that genes specifically involved in intrinsically regulated pro-apoptotic activity are primarily up-regulated, and those involved in extrinsically regulated pro-apoptotic activity plus those involved in anti-apoptotic activity are down-regulated in pluripotent cells. Thus, we confirmed differential expression of genes consistent with the maintenance of enhanced genetic integrity in pluripotent cells.
We next examined the mechanistic relationship between pluripotency and enhanced maintenance of genetic integrity at the genomic level by mining published cistrome data bases describing binding of the pluripotency factors OCT-4, SOX-2 and NANOG to target genes in pluripotent cells. We found evidence for direct binding ('first-degree interactions') of pluripotency factors to several of the genetic integrity (DNA repair and cell death) genes that are differentially expressed in pluripotent cells. In addition, we found evidence of indirect ('second-degree') interactions between pluripotency factors and genetic integrity genes mediated by binding of pluripotency factors to genes encoding transcription factors that, in turn, bind to differentially expressed genetic integrity genes. Thus, we demonstrate extensive interactions between the pluripotency and genetic integrity gene networks at the genomic level in pluripotent cells, and suggest that differential regulation (predominantly up-regulation) of genetic integrity genes is a fundamental readout of pluripotency which leads to enhanced maintenance of genetic integrity in pluripotent cells relative to differentiated cells.

AN IMPORTANT ROLE FOR CDK1 IN CELL CYCLE REGULATION, CHECKPOINT CONTROL AND APOPTOSIS IN HUMAN EMBRYOINNIC STEM CELLS (HESC) REVEALED BY RNA INTERFERENCE STUDIES

Irina Neganova
Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom

We have shown in our previous studies that members of the cyclin-dependent kinase (CDKs) family show cell cycle dependent expression and in particular, one member of this family, CDK2 plays an important role in G1 to S transition and checkpoint regulation, DNA damage response and maintenance of pluripotency in hESC. In this study we have focused on the role of a closely connected CDK family member, CDK1. Our study shows that downregulation of CDK1 by RNA interference results in accumulation of hESC at G2 -phase of the cell cycle, polyploidy and loss of hESC pluripotency. Downregulation of CDK1, also induced downregulation of CHK2 and altered the maintenance of G2 checkpoint arrest, despite having no effect on its initial activation via CHK1. In addition, reduced expression

of Survivin, BCL2 and BCL-XL was observed together with increased expression of cleaved PARP1, a typical marker of apoptosis, suggesting that CDK1 downregulation may render hESC more sensitive to apoptosis. Yet, the level of pro-apoptotic active form of BAX was reduced and there were no changes in Caspase 3 or 9 activation , indicating that while apoptotic processes are initiated, final commitment is impaired upon CDK1 downregulation. Together, these data indicate that CDK1 has multiple roles in cell cycle progression, maintenance of pluripotency and cytokinetic stability as well as apoptosis execution.

CHARACTERIZATION OF SEVEN HUMAN EMBRYONIC STEM CELL LINES (SNUHES32, 33, 34, 35, 36, 37 AND 38) DERIVED UNDER XENO-FREE CONDITIONS

Hye Won Seol[1], Jin Ah Baek[1], Juwon Jung[1], Bo Ae Yoon[1], Sun Kyung Oh[2], Hee Sun Kim[2], Seung-Yup Ku[2], Seok Hyun Kim[2], Shin Yong Moon[2], Young Min Choi[2]

[1]Institute of Reproductive Medicine and Population, Medical Research Center, Seoul National University, Seoul, Korea, Republic of, [2]Department of Obstetrics and Gynecology, Seoul National University, College of Medicine, Seoul, Korea, Republic of

INTRODUCTION: Human embryonic stem cells (hESCs) have potential as an unlimited source for biological research as well as treatment of incurable disease. One of the crucial requirements to enable to clinical use of these cells is to eliminate the risk of xeno-transmitted infections and immunoreactions caused by animal origin products in conventional cell culture system.
MATERIALS and METHODS: We were isolated inner cell mass of the
blastocyst from frozen embryos with mechanical dissection method. Isolated cells were expanded in gradual xeno-free culture conditions and established. Derived hESC lines were characterized by DNA fingerprinting, HLA typing, karyotype, AP staining, immunocytochemistry analysis for pluripotent cell surface markers (SSEA-3, SSEA-4, Tra-1-60, Tra-1-81, Oct-4), RT-PCR for undifferentiated gene expression (SOX2, Nanog, hTERT, Rex-1), mycoplasma detection test, in vitro differentiation capacity using embryoid body (EB) formation and Neu5Gc contamination examination by FACs.
RESULTS: Two hESC lines (SNUhES32 & SNUhES33) were established from phase 1 xeno-free culture condition (human foreskin fibroblasts (HFFs) cultured by IMDM basal medium containing FBS + xeno-free medium + humanized cell substrate) and five cell lines (SNUhES34, 35, 36, 37 & 38) were established from phase 2 (HFFs cultured by IMDM medium containing human serum (HS) + xeno-free medium + humanized cell substrate). All cell lines were identified by DNA fingerprinting, HLA typing and karyotype and were successful for freeze & thaw. Currently, these cell lines were succeeded in maintaining the self-renewing capacity and pluripotency of hESCs for more than 80 passages.
CONCLUSION: We have derived seven clinical-grade hESC lines under phase 1 and phase 2 xeno-free culture conditions. These hESC lines can be used for research but also clinical application in cell therapy.

MAINTENANCE OF HESC LINES USING HUMANIZED CULTURE CONDITION

Jin Ah Baek[1], Hye Won Seol[1], Juwon Jung[1], Bo Ae Yoon[1], Hee Sun Kim[2], Sun Kyung Oh[1], Seung Yup Ku[2], Shin Yong Moon[2], Young Min Choi[2]

[1]Institute of Reproductive Medicine and Population, Medical Research Center, Seoul National University, Seoul, Korea, Republic of, [2]Department of Obstetrics and Gynecology, Seoul National University, College of Medicine, Seoul, Korea, Republic of

INTRODUCTION: Human embryonic stem cells (hESCs) have the capacity to differentiate into all cell types, therefore holding the promise to be used in cell therapeutic applications. However, conventional culture conditions contain animal-derived components that bear the risk of transmitting non-human pathogens and incorporating non-human immunogenic molecules to hESCs. For these reasons, the research focus of hESC culture systems has been moving towards clinical applications. We report the development of a humanized culture condition without animal-derived material for clean-up using previously established hESC lines in this study.

METHODS: We set up the standardized culture condition using humanized materials, including CELLstart^{TM}, human foreskin fibroblast and a xeno-free medium containing knockOut^{TM} SR XenoFree (XF medium). After verifying the possibility of undifferentiated growth of SNUhES4 and H1 by replacing gelatin with CELLstart^{TM}, we used two different methods for maintaining cells in culture: sequential adaptation and direct adaptation. The former adapts in gradually increasing the ratios in the XF medium for the first four passages (25:75, 50:50, 75:25 and 100:0), while the latter directly uses a 100% XF medium.

RESULTS: For the early passages, both methods of humanized culture condition resulted in lower attachment rates and higher spontaneous differentiation rates, compared to conventional condition. Notably, the sequential adaptation method was more stable than the direct adaptation one. However, after further passages, both methods produced the same hESC characterizations as that of conventional culture condition, including morphology, growth behavior, expression of cell surface markers and stable karyotype. Finally, we observed that most of hESCs were negative for Neu5Gc (N-glycolyneuraminic acid, non-human immunogenic molecules) in humanized culture condition.

CONCLUSION: This study indicates that humanized culture condition of simplified compositions can be applicable to further culture optimization of hESC in a xeno-free medium without the loss of pluripotency and contamination of xenogenic sources. Clean-up of the hESC lines using this humanized culture condition would take one step closer to therapeutic applications. This research was supported by the Bio & Medical Technology Development Program of the National Research Foundation (NRF) funded by the Korean government (MEST) (2012M3A9C6049722)

W-2323

THE COMPARISON OF VARIOUS CONDITIONS AFFECTED ON SLOW-FREEZING OF HUMAN EMBRYONIC STEM

Jeoung Eun Lee, **Yuri Kim**, Myung Sun Shim, Sung-Geum Lee, Dong Ryul Lee
CHA Stem Cell Institute, CHA University, Seoul, Korea, Republic of

Successful cryopreservation of human Embryonic Stem Cells (hESCs) is able to preserve early passage stocks of hESCs and to facilitate worldwide distribution to researchers. There are two cryopreservation methods used for hESCs: vitrification and slow freezing with rapid thawing. Although several studies have reported 70~90% survival rates using various protocols, vitrification has several limitations preventing its widespread use such as the possibility of contaminating hESCs with infectious agents via contact with liquid nitrogen and very small volume of hESCs cryopreservation at once. Cryopreservation of hESCs using slow-freezing method might be suitable for large scale preservation but does not yet produce good results as much as in vitrification. Therefore, the optimization of several factors affected on hESC cryopreservation is needed. In this study, we tested the effect of DMSO concentration and the sodium ion in freezing medium on survival of hESCs after freezing and thawing in order to optimize the cryopreservation protocol of hESCs. CHA-hES15 cell line, established and maintained in CHA Stem Cell Institute, Korea, was used for this study. We used 0.25 straws as a storage vessel and a programmed cell freezer, and DMSO as a cryoprotectant for hESC slow-freezing. We collected clumps mechanically from hESC colonies for freezing and added freezing medium in two-steps. At first, we tested the effect of DMSO concentration on survival of hESCs after freezing and thawing; 10% DMSO+90% SR (A) and 5% DMSO+90% SR+5% DMEM/F12 (B). Then, we tested the effect of sodium ion in freezing medium; 10% DMSO+90% SR (C), 10% DMSO+20%SR+70% CJ2 (low sodium choline based medium) (D), and 10% DMSO+20%SR+70% M-CJ2 (modified CJ2 medium that sodium chloride replaces choline chloride) (E). We compared the colony forming rate of cryopreserved hESCs using various freezing media on fifth day after thawing. The Chi-square test was used for determining significant differences. The colony forming rates of group A, and C were 56.7% and 9.6%* (* P<0.001) respectively, in comparison of the DMSO con-

centration. The colony forming rates of group C, D and E for the effect of sodium ion on cryopreservation were 69.23%, 73.15% and 57.41%* (* P<0.05) respectively. The spontaneous differentiation rate (totally or ≥50% partially differentiated colony) was not significantly differentiated between all groups. From the results, the reduction of DMSO concentration (10% to 5%) in freezing medium was not appropriate for hESC cryopreservation, and the sodium ion in freezing media had a negative effect in survival of hESCs. Therefore, it is supposed that 10% DMSO, 20% SR and the rest of choline based medium (low sodium) might be an ideal freezing medium for efficient and cost effective hESC cryopreservation.

W-2324

ENDOPLASMIC RETICULUM PLAYS AN IMPORTANT ROLE IN THE REGULATION OF CALCIUM SIGNALING IN HUMAN EMBRYONIC STEM CELLS

Jijun Huang, Min Zhang, He Liang, Peng Zhang, Huang-Tian Yang
Key Laboratory of Stem Cell Biology, Institute of Health Sciences, Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS) & Shanghai Jiao Tong University School of Medicine (SJTUSM), Shanghai, China

Human embryonic stem cells (hESCs), derived from the inner cell mass of blastocyst, have the ability to propagate indefinitely in culture while still remain the capacity to differentiate into all somatic cell types of three germ layers. Thus they are not only a potentially inexhaustible resource for the repair and restoration of organ functions but also a unique model for the study of human early development process. So far, much progress has been achieved on the understanding of regulatory mechanism of self-renewal and differentiation in hESCs, including the key transcription factors, signaling pathways and epigenetic regulators. However, little is known about the physiological properties and regulations of hESCs, including calcium (Ca^{2+}) signaling systems, while such knowledge would enrich our understanding of the characteristics of pluripotency, the regulation of self-renewal, such as the switch of cell cycle and the signaling response to extracellular stimuli, and the cell fate decision. Previous studies from other and our laboratories have demonstrated that Ca^{2+} signaling plays an important role in cell cycle regulation and cell lineage specification of mouse ESCs. In the present study, we aimed to (i) characterize Ca^{2+} signaling in hESCs; and (ii) elucidate the regulatory mechanism of Ca^{2+} signaling in hESCs. We therefore determined expression profiles of genes coding for major Ca^{2+} handling proteins in hESCs and then investigated the function of these proteins by using confocal Ca^{2+} imaging and flow-cytometry analysis, combined with pharmacological approaches and small RNA interference technique. When adenosine triphosphate was delivered to hESCs, which activates inositol-1,4,5-triphosphate receptors (IP_3Rs) in the endoplasmic reticulum (ER), a transient increase of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) was detected. Such effect was partially inhibited by the pretreatment of the specific IP_3Rs antagonists, suggesting the involvement of IP_3Rs. Using an extracellular solution with high Ca^{2+} concentration, store operated Ca^{2+} entry (SOCE) was observed when intracellular Ca^{2+} stores were depleted by ER Ca^{2+}-ATPase blocker, and it was significantly changed after knock-down of IP_3Rs in hESCs. Inhibition of plasma membrane Ca^{2+} pump induced a large but slow increase of $[Ca^{2+}]_i$, while the Na^+/Ca^{2+} exchanger inhibitor induced a fast $[Ca^{2+}]_i$ elevation. These results indicate that hESCs already have a molecular basis to response extracellular stimuli by mobilizing a robust Ca^{2+} signaling regulatory cascade. Among it, the ER IP_3Rs-released Ca^{2+} plays an important role and store-operated Ca^{2+} channel mediated SOCE might be responsible for the Ca^{2+} refill after ER exhaustion.

BCL2L1 IS THE KEY DRIVER OF 20Q11.21 GAINS IN HUMAN EMBRYONIC STEM CELLS

Ha T. Nguyen, Mieke Geens, Afroditi Mertzanidou, Kurt Jacobs, Karen Sermon, Claudia Spits
Reproduction and Genetics, Vrije Universiteit Brussel, Brussels, Belgium

BCL2L1 is the key driver of 20q11.21 gains in human embryonic stem cells

Ha T. Nguyen, Mieke Geens, Afroditi Mertzanidou, Kurt Jacobs, Karen Sermon, Claudia Spits
Research Group Reproduction and Genetics, Vrije Universiteit Brussel. Laarbeeklaan 101, 1090 Jette, Brussels.
Gain of 20q11.21 is a chromosomal abnormality that is recurrently found in human pluripotent stem cells and cancers, strongly suggesting that this mutation confers a selective advantage to these cells. In this work we studied three human embryonic stem cell (hESC) lines that acquired a 20q11.21 duplication during in vitro culture. Transcriptome analysis revealed that none of the genes located in the common region of duplication was consistently upregulated. On the other hand, the genes *CHCHD2* and *TRPC6*, located elsewhere in the genome, showed a strong and consistent change of expression in the mutant cells. These genes pointed towards the RhoA activation pathway, which in hESC is activated upon loss of cell-to-cell contact. This pathway lays upstream of *BCL2L1*, one of the genes located in the common region of duplication. We found that although the mRNA levels of Bcl-xL (the anti-apoptotic isoform of *BCL2L1*) were unchanged in mutant cells, the protein was 2-4 times more abundant. Furthermore, the phenotype of the mutant cells was consistent with Bcl-xL overexpression, with markedly decreased apoptosis after single-cell dissociation and increased clonogenic capacity. The uncoupling between the mRNA and protein levels of *BCL2L1* suggests a post-transcriptional regulation by another factor located on the common region of duplication. We investigated *ID1* as a candidate regulator, but found no increased levels of the ID1 protein, nor activation of the NF-kB pathway in the mutant cells, which would be required for post-transcriptional regulation of *BCL2L1*, ruling out *ID1* as the post-transcriptional regulator of *BCL2L1*.

EFFECTIVE CRYOPRESERVATION OF HUMAN EMBRYONIC STEM CELL USING DIMETHYLSULPHOXIDE AND HYDROXYETHYLSTARCH COMBINATION.

Maristela Delgado Orellana[1], Gil Cunha De Santis[1], Danielle Aparecida Rosa Magalhães[1], Everton de Brito Oliveira Costa[1], Vivianane de Cássia Oliveira[2], Karen de Lima Prata[1], Patrícia Vianna Bonini Palma[1], Kuruvilla Joseph Abraham[3], Aparecida Maria Fontes[4], Dimas Tadeu Covas[1]
[1]Cell Biology, Regional Blood Center of Ribeirão Preto, Ribeirão Preto-São Paulo, Brazil, [2]Dentistry Department, Dentistry School of Ribeirão Preto, University of São Paulo, Ribeirão Preto-São Paulo, Brazil, [3]Department of Genetics, Medical School of Ribeirão Preto, University of São Paulo, Ribeirão Preto-São Paulo, Brazil, [4]Department of Genetics, Medical School of Ribeirão Preto, University of São Paulo, Ribeirão Preto-São Paulo, Brazil

Human embryonic stem cells (hESCs) are candidates for
many applications in the areas of regenerative medicine, tissue engineering,
basic scientific research as well as pharmacology and toxicology. An effective
freezing-thawing technique is crucial for clinical application and developing hESCs
banking. The aim of this study was to evaluate the recovery rate of
freezing/thawing hESCs using a combination of dimethylsulphoxide (DMSO) and
hydroxyethylstarch (HES) diluted in serum replacement (SR) solution. The efficiency of this cryopreservation solution
was evaluated in two slow-freezing applications in mechanical freezer (-80^{0}C)
and in a programmable cryopreservation system. This study shows for the first
time the combination of two cryoprotective reagents composed of HES, DMSO in SR
solution to establish a new slow-freezing protocol with high recovery rates of
undifferentiated hESC. The use of 10%
DMSO + 20% HES + 70% SR medium combined with mechanical detachment protocol in programmable
and in mechanical freezer leads to efficient hESC cryopreservation. We showed
that the recovery rates of hESC colonies (in programmable and in mechanical
freezer, respectively) with 10% DMSO + 20% HES + 70% SR medium were higher than
with Defined-medium® (3.88 and 2.9 vs 1.05 and 1.07; p = 0.000006903 and p =
0.04322) and higher than with classical medium 10% DMSO + 20% SR +70% DMEM
(3,88 and 2.9 vs 0.5 and 0.51, p = 0.0005136 and p = 0.0004253). Furthermore, after

thawing hESCs showed typical morphological characteristics, were positive for expression pluripotent markers, could still differentiate into the 3 germ layers, and showed normal karyotype. This new protocol allows, using simple steps without dedicated instrumentation, an efficient and economical hESC cryopreservation, ideal for hESC banking.

W-2327

PRDM14 INTERACTS WITH NANOG IN HUMAN EMBRYONIC STEM CELLS

Yun Shen Winston Chan
Genome institute of Singapore, Singapore, Singapore

Human embryonic stem cells (ESC) defined by their ability to self-renew indefinitely and to give rise to all adult cell types, are potentially invaluable in the field of regenerative medicine. However, this expanded cell fate potency also proves to be a hurdle for precise control of human ESC differentiation for various applications. Without detailed knowledge on how this cellular plasticity is regulated, their full potential remains to be harnessed. PRDM14 was identified in a genome-wide RNAi screen as an important determinant of the human ESC identity. PRDM14 binding across the human genome highly overlaps with the core pluripotency factor, highlighting the importance of PRDM14 in the core regulatory network. To further evaluate the importance of PRDM14 in the pluripotency network, its interaction with the core pluripotency regulators was investigated. PRDM14 was found to interact with NANOG via biochemical assays. This interaction was also reflected in their binding activities at genomic loci near pluripotency associated genes. Importantly PRDM14 and NANOG works in synergy to enhance transcriptional activity, supporting that this interaction is functional for gene regulation in hESC.

GENOME-WIDE ANALYSIS OF MRNA TARGETS AND PROTEIN PARTNERS OF PUMILIO 1 IN MAINTAINING HESC PLURIPOTENCY

Yinghong Ma
Yale Stem Cell Center, Yale University, new Haven, CT, United States

Genome-wide Analysis of mRNA Targets and Protein Partners of PUMILIO 1 in Maintaining hESC Pluripotency
Yinghong Ma1*, Xiao Huang1*, Lin Geng1, Katherine Uyhazi1, Min Cang 1,2, Linfeng Wu 3, Michael Snyder3, Caihong Qiu1 and Haifan Lin1 1. Yale Stem Cell Center, Cell Biology, Yale University School of Medicine,10 Amistad St, New Haven, CT 06510; 2. Inner Mongolia University, Huhtot, China; 3. Stanford University, Stanford, CA; *co-first author.
Human embryonic stem cells (hESCs) are capable of self-renewal and differentiation into all cell types in the human body, thus they hold great potential for understanding human development and for regenerative medicine. Research on the genetic regulation of hESC self-renewal and differentiation has been mostly focused on epigenetic and transcriptional regulation. Little is known about the posttranscriptional regulation at the levels of mRNA stability and translation efficiency, which are also crucial to hESC self-renewal and differentiation. The Drosophila pumilio (pum) gene serves as a translational regulator to modulate gene expression by binding to the 3' untranslated regions (3'UTR) of their mRNAs. Our group previously demonstrated that Pum protein is essential for germline stem cell maintenance in Drosophila. Here we show that both PUM proteins in humans, PUM1 and PUM2, are abundantly expressed in hESCs and are predominately localized in the cytoplasm. Using RIP-ChIP assay, we identified hundreds of mRNA targets of PUM1 involved in several regulatory pathways, including translational regulation and apoptotic response. These mRNAs contain the conserved Pum binding sites, called Nanos Response Element (NRE), in their 3'-UTR. PUM1 does not affect the levels of the majority of PUM1-target mRNAs, as indicated by PUM1 knockdown experiments. This is consistent with the known role of PUM proteins in regulating translation but not mRNA stability. However, some of the target mRNAs are either up- or down-regulated in PUM1 knockdown hESCs, suggesting a new function of PUM1 in regulating the half-life of some of its target mRNAs. In order to explore how

PUM1 regulates its target mRNAs, we identified PUM1-interacting proteins by co-immunoprecipitation followed with mass spectrometry analysis. We are in the process of confirming the interaction between PUM1 and its putative partners.

LIF AND HORMONE-DEPENDENT STAT3 ACT COOPERATIVELY TO SUSTAIN SELF-RENEWAL OF HUMAN ES CELLS

Hongwei Chen, Fabrice Gonod, Claire Hamela, Pierre-Yves Bourillot, Pierre Savatier
Stem-cell and Brain Research Institute, INSERM U846, Bron, France

Human embryonic stem cells (hESCs) depend on FGF2 and Activin/Smad signaling to self-renew in the primed pluripotency state, as opposed to mouse embryonic stem cells (mESCs), which exploit LIF/Stat3 signaling to sustain naive pluripotency. It is not clear whether Stat3 can also sustain self-renewal of hESCs. To answer this question, we engineered both our newly derived hESC line Oscar and the H9 hESCs with STAT3-ER^{T2}, a mutant estrogen receptor fused to mouse STAT3, which can be stimulated specifically by tamoxifen. Expression of STAT3-ER^{T2} in the presence of tamoxifen activates STAT3 target genes and supports self-renewal of mESCs in the absence of LIF. By contrast, bFGF-dependent Oscar-STAT3-ER^{T2} cells (designated F-OS3) did not activate STAT3 target gene expression upon treatment with tamoxifen, and remained strictly dependent on bFGF for self-renewal in the undifferentiated state; However, treatment of F-OS3 cells with both 10,000 U/ml hLIF and 250 µM tamoxifen resulted in the activation of some, albeit not all, STAT3 target genes (*c-fos*, *junB*, *Icam1*, *Cyp1b1*, *Ier3*, *Klf5*, *Gbx2*, *Sp5*, *Socs2*, and *Socs3*). Upon propagation in the presence of both factors, the F-OS3 cells progressively lost their dependency on bFGF, and continued self-renewing in the undifferentiated state. This was evidenced by the formation of tight colonies expressing the alkaline phosphatase, the pluripotency-associated transcription factors Oct4, Nanog, Sox2, and SSEA4. The cells have been passaged up to 60 times while maintaining a normal karyotype (46, XY). They retained the capacity to differentiate into derivatives of the three embryonic germ layers both *in vitro* by formation of embryoid bodies, and *in vivo* by formation of teratomas. These new cells thus expressed the cardinal markers and properties of pluripotency. They were designated TL-OS3 (TL for tamoxifen + LIF-dependency). TL-OS3 cells were strictly dependent on both LIF and tamoxifen for differentiation blockade. Moreover, after LIF/tamoxifen withdrawal and bFGF supplementation, they could be reverted to bFGF-dependency (so-called R-OS3 cells). Similar results were obtained with the H9 hESC line. Whole transcriptome analysis with Affymetrix DNA arrays showed that F-OS3 and R-OS3 cells shared similar transcriptional profiles, whereas TL-OS3 cells had a distinct profile, characterized by the activation of STAT3 target genes. Moreover, the TL-OS3 cells became permissive to trypsinization into single cells and formed mouse ESC-like colonies when cultivated in a medium supplemented with GSK3 and MEK inhibitors (CHIR99021 and PD0325901, respectively). Furthermore, activation of a number of genes whose expression is associated with naive pluripotency in rodents was observed. Collectively, these results show that LIF and hormone-dependent Stat3, together with GSK3 and MEK inhibitors, can sustain the self-renewal of human ESC cells in a state close to naive pluripotency.

W-2332

THE ROLE OF LAMININ 511 IN HUMAN PLURIPOTENT STEM CELLS

Sanna Vuoristo, Diego Balboa Alonso, Jaan Palgi, Timo Tuuri, Timo Otonkoski
Biomedicum Stem Cell Center, University of Helsinki, Helsinki, Finland

Results from several laboratories have shown that the extracellular matrix protein laminin 511 (lm-511) is a suitable substrate for human pluripotent stem cell (hPSC) culture. We have previously shown that hPSC synthesize, secrete and deposit lm-511 and that the production of lm-511 is associated with undifferentiated hPSC cultures. However, hPSC colonies are heterogeneous; they contain the central undifferentiated hPSCs, the more peripheral “niche” cells and the differentiated hPSC derived feeder (hdf) like cells. Our aims were 1) to characterize the patterns and the relationship of the laminin alpha 5 (lm α5) and pluripotency and early differentiation marker expressions within

hPSC colonies by using single-cell qPCR and 2) to investigate the lm-511 secretion in hPSC cultures using analytical confocal microscopy.
In large hPSC colonies, lm α5 expression concentrates to the peripheral cells of the colony. The expression correlates inversely with that of OCT4 and positively with the expression of various differentiation related genes such as SOX17 and N-CADHERIN. In addition, hPSCs express a novel variant of the full-length lm α5. The novel variant RNA is significantly shorter than the full-length lm α5 chain and it is only expressed in the middle of the colonies. The expression of the known, full-length lm α5 chain and its variant correlate inversely.
Confocal microscopy analysis showed that the peripheral cells indeed secrete significantly more lm-511 as judged by several parameters. The peripheral cells contain more than twice the amount of lm-511 secretory vesicles than the middle cells and the vesicle size of the peripheral cells is nearly double of that in the middle cells. Therefore, hPSCs create a lm-511 middle-peripheral polarity in large colonies. Interestingly, soon after passaging lm 511 is homogenously present throughout the small, undifferentiated hPSC colonies, likely promoting cell adhesion and organization of the colonies.
Taken together, we show that hPSCs dynamically modify their lm-511 secretion. The small, undifferentiated colonies secrete lm-511 throughout the colonies, while expanded colonies create a middle-peripheral polarity. In large colonies the undifferentiated hPSCs express a truncated lm α5 chain whose function is currently not understood. Our findings provide fundamental evidence for lm 511 as an important component of the hPSC in vitro niche.

Embryonic Stem Cell Differentiation

W-2333

CARDIOMYOCYTE DIFFERENTIATION OF HUMAN INDUCED PLURIPOTENT STEM CELLS WITH THE STEMDIFF™ CARDIOMYOCYTE KIT

Jennifer Antonchuk, Reena Sandhu, Raymond Kwok, Cassie Ho, Terry E. Thomas, Allen C. Eaves, Sharon A. Louis
Research & Development, STEMCELL Technologies Inc, Vancouver, BC, Canada

Human pluripotent stem cells (PSCs) and induced pluripotent stem cells (iPSCs) have the potential to differentiate to any somatic lineage, given that specific inductive and/or inhibitory factors are added appropriately. A goal of this approach is to generate normal and disease-specific cardiomyocytes on which to test potential therapeutic agents for both their effectiveness and their toxicity. To this end, we have developed a defined, serum-free, feeder-free cell culture system for the directed differentiation of iPS cells into beating cardiomyocytes. To induce and promote differentiation, our system uses a monolayer culture with the multistep addition of a series of defined factors in specialized media at specific time points. The iPS cell lines tested to date include WLS-4D1 and WLS-1C (provided by Dr. William Stanford, Ottawa, Canada) and A13700 (from Life Technologies). Prior to differentiation, these iPS cell lines were maintained in mTeSR™1 on BD Matrigel©-coated plates. To initiate differentiation, mTeSR™1 was removed and replaced with STEMdiff™ Cardiomyocyte Basal Medium together with the addition of STEMdiff™ Cardiomyocyte Supplements A to D in a specific sequence over a period of 15 days. Synchronous beating was often visible in patches by day 12 and a synchronously beating cell sheet covering the whole well was formed by day 15. Cells from the indicated iPS cell lines were harvested on day 15 and analyzed by flow cytometry for expression of the intracellular cardiomyocyte marker cardiac troponin T (cTnT). Using this system, differentiated cells derived from WLS-4D1, WLS-1C and A13700 iPS cells expressed cTnT at a frequency of 44% (±27, n=10); 36% (±32, n=6); and 32% (±25, n=6), respectively. Work is on-going to further optimize the protocol, to reduce variability, and to functionally characterize the cardiomyocytes generated from iPS cells in this new culture system. The cardiomyocyte differentiation culture system described here is easy to use as it simply involves sequential media changes with cardiomyocyte-inducing factors in the STEMdiff™ Cardiomyocyte Media and Supplements, while maintaining the cells in their original feeder-free monolayer culture with no need for cell detachment, EB formation, or re-plating steps. In conclusion, these results demonstrate that the STEMdiff™ Cardiomyocyte Kit can be used to efficiently form beating cardiomyocytes from human iPS cells in a defined, feeder-free, monolayer culture system.

Myocardial infarction and heart failure are leading causes of death worldwide. Because the heart has very limited regenerative capacity, endogenous cell regeneration is not sufficient to repair heart damage. The concept of cell replacement has become an appealing therapy to treat such cardiac diseases. Human embryonic stem cells (hESC) are an attractive source for the cell replacement therapy since they can be greatly expanded in culture and differentiated into specific cell lineages under proper inductions. To provide sufficient hESC-derived cardiomyocytes for pre-clinical and clinical studies, a robust scalable differentiation system for cardiomyocyte production is essential. Previously we have established a scalable hESC suspension culture system with defined culture conditions. Using hESCs generated from the suspension culture system, we have developed a scalable differentiation process in adherent format, with which hESCs cultured on Matrigel are induced for cardiac differentiation by sequential treatment of Activin A and BMP4. This process has been applied to large-scale manufacturing of hESC-derived cardiomyocytes with 50-80% purity. For potential clinical application, we also develop a differentiation process with small molecule induction on cells grown on a defined matrix. Under this defined system, hESCs can be differentiated to cardiomyocytes with over 80% purity in a large scale vessel. We further use the small molecule induction approach to directly differentiate the hESC suspension culture in spinner flasks without matrix addition. With this scalable suspension culture system, we are able to obtain over 80% cardiomyocytes after differentiation. The suspension culture system from expansion of undifferentiated hESCs to cardiomyocyte differentiation provides a bioreactor prototype for automation of cell manufacturing. In summary, we have developed robust processes for scalable manufacturing of hESC-derived cardiomyocytes in both adherent and suspension culture systems that will accelerate the advance of pre-clinical and clinical studies.

CHARACTERISATION OF CARDIOMYOCYTE PROGENITOR CELLS ISOLATED USING NOVEL MONOCLONAL ANTIBODIES DURING THE DIFFERENTIATION OF HESCS TO CARDIOMYOCYTES

Hau Wan LEUNG[1], Jayanthi PADMANABHAN[1], Marie-Josè GOUMANS[2], Andre CHOO[1]

*[1]Stem Cells, Bioprocessing Technology Institute, A*STAR, Singapore, Singapore, [2]Dept of Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands*

The use of stem cell-derived cardiomyocytes in regenerative medicine is one of the envisioned goals of stem cell therapy. The current bottlenecks faced when deriving cardiomyocytes from pluripotent stem cells, such as human embryonic stem cells (hESCs) and induced pluripotent stem cells (iPSCs), would be low differentiation efficiencies for certain cell lines, and heterogeneity of the cell population obtained. We propose an alternative method to circumvent these problems by enriching for cardiac-committed cardiomyocyte progenitor cells (CMPCs) partway during hESC differentiation to cardiomyocytes using monoclonal antibodies (mAbs) specific to CMPCs. The aims of this study are: firstly, to generate novel mAbs specific to CMPCs using a surrogate CMPC line isolated from human heart tissue; and secondly, to characterise CMPCs isolated using these mAbs, both from hESC differentiation to cardiomyocytes, and also from human heart tissue.
We generated a panel of mouse mAbs against raised against primary CMPCs isolated using Sca-1 from human heart tissue (A. M. Smits et al (2009), Nature Protocols, 4(2), 232-243). From the panel of antibodies generated, 11 candidate antibodies were shortlisted based on their specificity towards CMPCs, but not human fibroblast or hESC by flow cytometry and immunocytochemistry. The binding profile of these 6 candidate mAbs were tracked during hESC differentiation to cardiomyocytes at various time points. We observed a temporal expression pattern for 4

of the mAbs, which showed a gradual increase of mAb binding during the initial stages of differentiation, peaking before or at the onset of beating areas, and subsequently decreased as the differentiation proceeded.
We have used one of these mAbs, mAb C19, to enrich for CMPCs during hESC to cardiac differentiation. These cells can be expanded and maintained for at least 10 passages, and under CMPC maintenance conditions, cardiac markers in the captured population are higher than the corresponding non-binding population. With the right differentiation cues, mAb C19-sorted cells can continue to differentiate into cardiomyocytes. To understand the gene expression profile associated with these mAb C19-sorted cells, microarray studies have also been performed on CMPCs sorted from both hESC differentiation and human fetal heart tissue. From this study, we have found that these CMPCs also have higher expression of genes related to endothelial and tube development. This result has been verified by cell angiogenesis assays.
In conclusion, we have generated a panel of mAbs that are specific against CMPCs. As a pilot study, mAb C19 have been used to enrich for CMPCs during hESC differentiation. These cells retain similar proliferation and differentiation capabilities compared with Sca-1 isolated CMPCs. In addition, these cells also show a propensity to differentiate to the endothelial lineage. This supports the use of our novel mAbs in the isolation and characterisation of CMPC populations with multi-lineage capacity during hESC differentiation.

SYSTEMATIC DISCOVERY OF TRANSCRIPTION FACTORS FOR CELL DIFFERENTIATION

Kohei Yamamizu[1], Alexei A. Sharov[1], Yulan Piao[1], Veronika Zsiros[2], Hong Yu[1], Kazu Nakazawa[2], David Schlessinger[1], Minoru SH Ko[1]

[1]National Institutes of Health, Baltimore, MD, United States, [2]National Institutes of Health, Bethesda, MD, United States

A network of transcription factors (TFs) determines cell identity, but identity can be altered by overexpressing a combination of TFs. In principle, this opens the possibility of achieving one of the goals of regenerative medicine - generating the desired differentiated cells from pluripotent stem cells, such as embryonic stem (ES) cells and induced pluripotent stem (iPS) cells. However, choosing and verifying combinations of TFs for specific cell differentiation has been daunting due to a large number of possible combinations of ~2,000 TFs. In this study, we show an unbiased approach to systematically identify TFs that can direct efficient and rapid cell differentiation. Previously, we have generated the global gene expression profiles obtained by overexpressing single TFs using the NIA mouse ES cell bank, which consists of 137 mouse ES cell lines. We start with the correlation matrix between the global gene expression responses to the induction of single TFs and the global gene expression profiles of a variety of tissues and organs. Based on the correlation matrix, we select TFs as examples and show that their overexpression differentiates ES cells into cells of specific organs, as predicted: Myod1 for skeletal muscles, Sfpi1 or Elf1 for blood cells, Hnf4a or Foxa1 for hepatocytes, and Ascl1 or Foxg1 for neurons. Furthermore, we show that transfection of synethetic mRNAs of Myod1, Sfpi1, Hnf4a, or Ascl1 generates specific target cells. These results demonstrate both the wide-ranging utility of this approach to identify potent TFs for cell differentiation, and also the unanticipated capacity of single TFs to directly guide differentiation to specific lineage fates.

GENOMIC INSTABILITY DURING EARLY DIFFERENTIATION OF EMBRYONIC STEM CELLS

CLARA I. ESTEBAN[1], HAROLD H. MORENO-ORTIZ[2], CAROLINA LUCENA[3], DWAYNE WISE[1], NANCY REICHERT[1]

[1]BIOLOGICAL SCIENCES DEPARTMENT, MISSISSIPPI STATE UNIVERSITY, STARKVILLE, MS, United States, [A]REPRODUCTIVE GENETICS, [B]STEM CELLS UNIT, [2]FERTILITY AND STERILITY COLOMBIAN CENTER-CECOLFES, BOGOTA, Colombia

Understanding how genomic instability could be involved in the regulation and establishment of cell lineage commitment during embryonic stem (ES) cell differentiation into an embryoid body (EB) would provide crucial know-

ledge of stem cell biology. Therefore, defining the signaling pathway that controls early cell fate decisions is an important focus of research. Here, we determine the degree of instability in single tandem repeat markers located near embryonic developmental genes responsible for pluripotency, differentiation, and imprinting of the ES cells. We determined that the mean values of instability frequencies in EB from H1 and H7 ES cell lines showed significant differences across time between ES cell lines. Markers that became unstable during spontaneous differentiation showed higher instability frequencies associated with pluripotency (D1S551), differentiation (D16S3034, D16S3090, D14S588, D11S4090, D3S1583, D1S468, DXS1208, D4S2623, and D18S63), and imprinting (IGF2PROM, GRB10PROM, HISTHB2, D6S2252, D2S144, D3S1611, D7S488, and D10S529). Genomic instability influences the loss of pluripotency and the gain of cell lineage specialization. Interestingly, the differentiation potential of EBs from the two stem cell lines varied. EBs from H1 were prone to neuroectoderm differentiation in comparison to EBs from H7, which showed functional differentiation into mesoderm in the form of contractile cardiac muscle. We suggest that genomic instability in repetitive regions could be a signal for cell fate decision during differentiation among ES cell lines. Our results indicate correlation of instability in specific markers located near developmental genes and epigenetic modulators in EB that underwent spontaneous differentiation in vitro. The significance of elucidating possible molecular mechanisms of genomic instability and validation of novel biomarkers could potentially lead to use of ES cell derivatives are safe source for cell tissue replacement in clinical applications.

ENGINEERED ADRENOMEDULLIN1 BASED NOVEL CELL-RECOGNIZABLE BIOMATERIAL IN REGENERATIVE MEDICINE

Kakon Nag[1], Kenji Kuwasako[2], Toshihiro Akaike[1]

[1]Department of Biomolecular Engineering, Tokyo Institute of Technology, Yokohama, Japan, [2]Frontier Science Research Center, University of Miyazaki, Miyazaki, Japan

Cell recognizable-biomaterials,
like cadherins, has been successfully applied in the
field of regenerative medicine
for efficient maintenance, conversion, and purification of targeted cells like
hepatocytes, neuronal cells, cardiac cells etc. from embryonic stem cells (ESC)
and induced pluripotent stem cells (iPSC). Despite the recent advancement of biomaterials
in regenerative medicine, still there are substantial needs for
novel biomaterials or engineered biomolecules to further potentiate this field.
In this study we are introducing engineered-adrenomedullin1 (AM1), a peptide
hormone-based novel biomaterial, in stem cell biology. AM1 is
a 52-residue peptide of calcitonin gene-related
peptide (CGRP) superfamily with multifaceted roles in physiology and development. It
signals
through heteromeric conformations of a member of G protein-coupled receptor
(GPCR), namely calcitonin receptor-like receptor (CLR) with the members of the
receptor activity modifying protein (RAMP) family, specifically RAMP2 and RAMP3.
We have now identified
that AM1 has critical roles in stem cell biology too. Particularly, spaciotemporal
AM1 supplementation increased mesendoderm proliferation in human ESC more than
200% over the commonly used recipe, and continued AM1 treatment significantly
enhanced endothelial cell population in the culture. We further revealed that
AM1-induced GPCR signalling enhances classical Notch1 - Delta4 pathway in ESC
and iPSC that consequently activates Hes1, which is responsible for the mesendoderm
population proliferation. Importantly, we found that AM1 has high affinity binding
sites on the surface of generated blood cells and endothelial cells. Based on this exciting
discovery we are currently working on engineering of AM1 to apply in stem cell

biology to enhance the productivity of target lineages, as well as on-site one-step purification of the target cells.

GLUCOSE AFFECTS OSTEOGENIC ESC DIFFERENTIATION BY ALTERATIONS IN MICRORNA EXPRESSION

Anke Dienelt, Doreen Babin, Dorota Kaniowska, Nicole I. zur Nieden
Department of Cell Therapy, Applied Stem Cell Technologies Unit, Fraunhofer Institute for Immunology and Cell Therapy, Leipzig, Germany

With increasing average age of the world population and changes in nutritional habits, diabetes is becoming a more and more prevalent disease. Long-term metabolic changes associated with diabetes, such as high blood glucose levels, can lead to severe complications affecting bone regeneration and turnover. In addition, diabetic pregnancies go along with an increased risk for the fetus to develop skeletal malformations. However, the molecular mechanisms of glucose-induced teratogenesis have insufficiently been described.
In previous studies, we have reported that skeletal malformations in the offspring of diabetic mothers can be mimicked in vitro using embryonic stem cell (ESC) differentiations into osteoblasts. In exploring embryonic bone formation in vitro we showed that diabetic glucose [4.5 g/l (25 mM)] down-regulates mRNAs specific for mature osteoblasts, whereas collagen secretion and Col1 mRNA, associated with osteoprogenitors, were enhanced. Our experiments also revealed a decreased presence of osteoclasts in diabetic glucose. Together, these data led us to believe that the bone specific phenotypes seen in newborns of diabetic mothers may originate from insufficient maturation of osteoblast and -clast precursors.
Here we aimed to identify whether the impaired differentiation in high glucose concentrations was regulated by short non-coding microRNAs (miRNAs). Microarray studies were performed to reveal the expression of miRNAs at diverse time points during early murine ESC differentiation. We identified four miRNAs to be differentially expressed during early differentiation under high (25mM, diabetic) and low glucose (5 mM, physiological) conditions: mmu-mir-28, mmu-mir-125-5p, mmu-mir-199a-5p and mmu-mir-377. In order to test whether these specific miRNAs regulated differentiation fate, overexpression studies were then performed. Upon miRNA overexpression, osteogenic differentiation fate was evaluated by determining the amount of calcified matrix deposition and by analyzing osteogenic gene expression via quantitative PCR.
Overexpression of the four miRNAs significantly altered the calcification of osteogenically induced cultures and even those that were uninduced and left to spontaneously differentiate. Additionally, we found that an overexpression of the miRNAs lead to significant changes in the expression of mRNAs specific to the osteogenic lineage including Col1, osteocalcin and osteopontin. Moreover, mRNA levels for the calcitonin receptor, which is associated with an osteoclast phenotype, were also altered upon miRNA overexpression.
In summary, we were able to show that differentiation of mESCs in different glucose concentrations impacts early differentiation by affecting expression of specific miRNAs. In turn, overexpression of these distinct miRNAs leads to alterations in the formation of osteoclast and osteoblasts and is thus likely to impact the balance between those cell types during the process of osteogenesis.

AN IN DEPTH TRANSCRIPTIONAL ANALYSIS OF HUMAN CORTICAL DEVELOPMENT USING PLURIPOTENT STEM CELLS

Joyce Van de Leemput[1], Nathan Boles[1], Patty Lederman[1], Boaz Levi[2], Vilas Menon[2], Refugio Martinez[2], Changkyu Lee[2], Shuyuan Yao[2], Ajamete Kaykas[2], Carol Thompson[2], Sally Temple[1], **Christopher A. Fasano**[1]
[1]Neural Stem Cell Institute, Rensselaer, NY, United States, [2]Allen Institute for Brain Science, Seattle, WA, United States

Many neurological and psychiatric disorders have pathophysiologies with a strong cerebral cortical component. A clearer understanding of normal human corticogenesis will provide insight into these diseases. Recent studies have

reported the derivation of cerebral cortical cells from human embryonic stem cells (hESC) that recapitulates salient features of cortical layer formation. To date, however, an in depth transcriptome analysis of how cortical layers are generated over time has not been performed. Using a differentiation paradigm modified from previous protocols and RNA-Seq, we report the first comprehensive temporal gene expression dataset encompassing the breadth of human cortical development. Applying biocomputational techniques and clustering analysis, genes that change significantly over the time-course were grouped based on specific temporal patterns of expression. Known layer markers arise appropriately within these defined temporal groups, with deep layer markers arising before superficial layer markers. Using gene ontology and pathway analysis, we linked categories and pathways associated with neural development to these groups. Finally, we found enrichment for several neurological diseases and disorders in specific gene clusters. This data set is the first to describe the dynamic transcriptome of human cerebral cortical development and provides the basis of a resource to aid studies into normal human brain development and into neurological disorders such as autism and Alzheimer's disease.

THE HISTONE DEACETYLASE SIRT6 REGULATES STEM CELL DIFFERENTIATION

Jean-Pierre Etchegaray[1], jiho choi[1], Cesar Sommer[2], Yun Huang[4], xue wang[4], Dafne M. Silberman[1], Konrad Hochedlinger[5], Gustavo Mostoslavsky[3], Anjana Rao[6], Raul Mostoslavsky[1]

[1]MGH- Cancer Center, Mass General Hospital - Cancer Center - Harvard Medical School, Boston, MA, United States, [A]Section of Gastroenterology, Department of Medicine, [B]Gastroenterology, Department of Medicine, [2]Boston University School of Medicine, Boston, MA, United States, [3]La Jolla Institute for Allergy & Immunology, La Jolla Institute for Allergy & Immunology, La Jolla, CA, United States, [4]Department of Stem Cell and Regenerative Biology at Harvard University and Harvard Medical School, Howard Hughes Medical Institute at Massachusetts General Hospital Cancer Center and Center for Regenerative Medicine, Boston, MA, United States, [5]La Jolla Institute for Allergy & Immunology4, La Jolla Institute for Allergy & Immunology4, La Jolla, CA, United States

In mammals, chromatin dynamics plays a critical role in developmental programs and pluripotency state of embryonic stem (ES) cells. Acetylation of histone H3 at lysine 56 is an epigenetic mark implicated in maintaining pluripotency of ES cells, although its molecular mechanism and its role in development remain unknown. We and others found that the histone deacetylase SIRT6 specifically targets acetylated H3K9 (acH3K9) and H3K56 (acH3K56), which are epigenetic marks linked to activation of gene expression, and therefore, propose to determine its role in pluripotency and embryogenesis. Our data show that ES cells derived from SIRT6 knockout mice are defective in their ability to differentiate towards endoderm and mesoderm, while promoting neuroectoderm development. We found this phenotype to be associated with de-repression of the core pluripotent genes Oct4, Sox2 and Nanog, caused by the recruitment of SIRT6 and deacetylation of H3K56ac at their promoter regions. Consequently, SIRT6-depleted Embryoid Bodies (EB) exhibit abnormally high expression levels of these core pluripotent genes. Moreover, we found SIRT6 to be an upstream regulator in an epistatic pathway involving the dioxygenases TET1 and TET2, implicated in the conversion of 5-methyl cytosine (5mC) into 5-hydroxylmethyl cytosine (5hmC), which is a critical step required for DNA dimethylation, during early embryogenesis and reprogramming of induced pluripotent stem (iPS) cells. Genome-wide analysis in SIRT6 knockout ES cells unraveled neuroectoderm genes as targets for 5hmC, which is an epigenetic mark required for transcription activation. This is consistent to the neuroectoderm prone developmental defect of SIRT6-depleted EB. Importantly, we find the role of SIRT6 in differentiation of stem cells to be recapitulated in human ES cells. Therefore, we propose SIRT6 as a master regulator safeguarding the balance between pluripotency and differentiation during early stages of embryogenesis, and also as a molecular tool to elucidate novel genetic programs required for efficiency of iPS formation. Overall, the role of SIRT6 in balancing molecular and genetic programs during pluripotency and cellular differentiation, and its conserved mechanisms of action from mouse to human, could potentially give rise to novel approaches in regenerative medicine.

W-2346

DISCOVERY OF CONSENSUS GENE SIGNATURE AND INTERMODULAR CONNECTIVITY DEFINING THE STEMNESS OF HESCS

Jeffrey J. Kim, Omar Khalid, AmirHosien Namazi, Thanh Tu, Yong Kim
Laboratory of Stem Cell and Cancer Epigenetic Research, UCLA, Los Angeles, CA, United States

Objective: Molecular markers for stemness have been identified mostly by relative comparisons between undifferentiated cells versus differentiated cells to define the characteristics of stem cells including human embryonic stem cells (hESCs) and induced pluripotent stem cells (iPSCs). The heterogeneity in molecular signatures of hESCs depending on various experimental conditions led us to question if there are any true consensus molecular markers that define "stemness". We hypothesize that there are a set of genes that are consistently altered in human embryonic stem cells (hESCs) regardless of differentiation conditions.
Methods: To identify these consensus stemness molecular markers, we have performed a microarray analysis of H1 and H9 hESCs and compared and validated our results to 19 publicly available microarray data. Using WGCNA we have constructed consensus modules to identify differentially regulated genes during differentiation.
Results: In addition to some of the well-known stemness markers such as *OCT4* and *NANOG*, we have identified potential new markers for stemness and differentiation. Moreover, we have validated some of the top downregulated markers (*LCK*, *KLKB1* and *SLC7A3*) and the top upregulated markers (*RHOJ*, *ZEB2* and *ADAM12*) upon differentiation, which were discovered from combined analyses of our transcriptomic profiling and bioinformatics of public data sets. Furthermore, we have for the first time designated stem cell markers to specific interactive networks in the genome, identifying possible interacting partners and showing how the markers themselves relate to each other by using Cytoscape and HIVE plots.
Conclusion: Identification of new stemness markers, interacting partners and interconnectivity analyses may contribute in explaining the mechanism of stem cell self-renewal and differentiation. These novel stemness markers and our bioinformatic analyses will also serve as useful tools in various applications for delineating stemness of different cell types.

W-2347

ADAPTATION OF STRIATAL IN VITRO DIFFERENTIATION OF HUMAN STEM CELLS TO HIGHER THROUGHPUT APPLICATIONS

Sandra Lubitz[1], Jamshid Arjomand[2], Jasmin Dreyer[1], Mareen Glausch[1], Stefan Jäger[1], Ryan Schönfeld[3], Celia Dominguez[3], Ignacio Munoz-Sanjuan[3]
[1]Evotec, Hamburg, Germany, [2]CHDI Management, Inc., Princeton, NJ, United States, [3]CHDI Management, Inc., Los Angeles, CA, United States

In vitro differentiation of human stem cells facilitates the generation of unlimited numbers of post-mitotic neurons as a tool for basic research, target identification, target validation, and drug discovery efforts in Huntington's Disease (HD). In order to meet requirements for high content analyses, neural conversion of human embryonic stem cells (hESC) was achieved under defined adherent conditions. The protocol described here had been further optimized to direct primitive neuroepithelia towards striatal lineage ($Dlx5^+/Gsx2^+$) and enable scale up for screening. Characterization of *in vitro* derived progenies is routinely being performed on the OPERA system, a fully automated confocal microplate reader for high content imaging and high throughput screening. This technology offers image-based quantification of cell fate-specific markers and analysis of phenotypic readouts of HD in mixed populations upon comprehensive time course analyses without the need to achieve essentially pure populations of neural cell types. Optimization of striatal differentiation was accomplished using a well characterized hESC line (H9) and this protocol will soon be applied to human stem cells expressing mutant Huntingtin. Overall, this stem cell based approach has been shown to fulfill the main criteria for lineage-specific differentiation, such as efficiency and robustness, thereby providing a sophisticated *in vitro* human cell-based system to explore mechanisms relevant to striatal commitment and for understanding HD pathogenesis.

TBX3 DIRECTS CELL FATE DECISION TOWARDS MESENDODERM

Clair E. Weidgang[1], **Ronan Russell**[1], Tata R. Purushothama R.[3], Susanne J. Kühl[2], Thomas Seufferlein[1], Martin Zenke[4], Michelina Iacovino[5], Michael Kyba[5], Hans R. Schöler[6], Michael Kühl[7], Sebastian J. Arnold[8], Stefan Liebau[9], Alexander Kleger[1]

[A]Department for Internal Medicine I, [B]Institute for Biochemistry and Molecular Biology, [1]University Ulm, Ulm, Germany, [2]Center for Regenerative Medicine, Harvard Stem Cell Institute, Massachusetts General Hospital, Boston, MA, USA, NY, United States, [3]Department of Cell Biology,, Institute for Biomedical Engineering, Medical Faculty,Rheinisch-Westfälische Technische Hochschule, Aachen, Germany, [4]Department of Pediatrics, Lillehei Heart Institute, University of Minnesota, MN, United States, [5]Department of Cell and Developmental Biology, Max Planck Institute for Molecular Biomedicine, Münster, Germany, Germany, [6]Institute for Biochemistry and Molecular Biology, Ulm University, Germany, [7]University Medical Renal Department, University Medical Centre, Centre for Clinical Research, Freiburg, Germany, Germany, [8]Institute for Anatomy & Cell Biology, Ulm University, Germany

To date, the mechanisms governing transition from the pluripotent state to the onset of differentiation are poorly understood. Recent reports demonstrated additional functions of pluripotency-associated factors during early lineage commitment. Interestingly, the T-box transcription factor Tbx3 has been implicated in the regulation of embryonic stem cell (ESC) self-renewal and in cardiac differentiation. In the current study, we report previously unappreciated roles of Tbx3 in early lineage commitment. We show that Tbx3 is dynamically expressed during specification of the mesendoderm lineages in differentiating ESCs in vitro and in developing mouse and Xenopus embryos in vivo. Our results demonstrate that Tbx3 exerts dual cell autonomous and non-cell autonomous effects, directly activating key lineage specification factors while also activating a Nodal/Smad2 signaling signature. Finally we establish that complex compensatory mechanisms are at play such that there is a functional redundancy between Tbx3 and the closely related family member Tbx2, presumably to protect the progression of normal development. Taken together, we define novel facets of Tbx3 actions and map Tbx3 as a central upstream regulator of the mesendoderm transcriptional program.

W-2351

QUANTIFYING HUMAN ENDODERM DEVELOPMENT IN TERATOMAS

Jennifer Hesson, Patricia Kensel-Hammes, Savannah Cook, Antonio Jimenez-Caliani, Laura Crisa, Carol Ware, Vincenzo Cirulli

ISCRM, University of Washington, Seattle, WA, United States

Teratomas have been conventionally used in the context of pluripotent stem cells to identify ability to generate cells of all three embryonic lineages. In this context, these lineages are usually not quantified, nor is the extent and appropriateness of development measured due to the complexities of these measures. Using naïve and primed human embryonic stem cells (hESC) we noted a difference in the ability to generate endoderm within teratomas and the extent and context of development differed between the two pluripotency stages. We describe three methods to measure endodermal developmental ability of these lines by histological section of teratomas and through in vitro assays of differentiation (directed to definitive endoderm vs. non-directed differentiation). Histological sections are measured by surface area labeled by specific antibodies, while in vitro assays are measure through FLOW for endodermal lineage markers. Our findings will be discussed in the context of garnering more valuable information from the teratoma assay than is currently recorded.

W-2352

E2F6 MEDIATED EPIGENETIC SILENCING OF GERMLINE GENES DURING THE TRANSITION FROM GROUND TO PRIMED STATE PLURIPOTENCY REQUIRES EZH2

Milena Leseva, Katherine Santostefano, Amy Rosenbluth, Naohiro Terada
Pathology, University of Florida, Gainesville, FL, United States

The transcriptional repressor E2f6 is known to negatively regulate a set of germline genes in somatic tissues and can function together with Dnmt3b in this context. In addition, E2f6 has been described as a subunit of polycomb repressive complexes with chromatin modifying activities. However, neither the precise molecular mechanisms, nor the exact timing of E2f6-mediated gene repression are fully understood. To elucidate the cross-talk between these repressive machineries we performed gene expression analysis, bisulfite DNA sequencing and chromatin immunoprecipitations in mouse pluripotent stem cells and their differentiating descendants. Initially, we demonstrate that deletion of E2f6 in mouse embryonic fibroblasts leads to promoter de-repression and hypomethylation. We show that E2f6-dependent germline promoters are first silenced and targeted for *de novo* methylation in epiblast stem cells (EpiSCs), the *in vitro* counterpart of the post-implantation epiblast. Interestingly, this occurs despite similar occupancy of E2f6 at the promoters of its target genes in both embryonic stem cells (ESCs) and EpiSCs. Consistent with these observations, stable overexpression of E2f6 or Dnmt3b in ESCs does not induce gene silencing or promoter methylation in the ground pluripotency state. We propose that additional factors are required for E2f6-mediated germline gene silencing during the transition from a ground-to-primed pluripotency state. Using a SET domain deletion mutant of Ezh2 we demonstrate the requirement of the H3K27 trimethylation activity for repression initiation of the *Stag3* and *Smc1β* promoters during terminal differentiation.

W-2353

DYNAMICS OF X CHROMOSOME INACTIVATION

Friedemann Loos, Joost Gribnau
Reproduction & Development, Erasmus MC, Rotterdam, Netherlands

In heterogametic species, dosage compensation evolved to account for the difference in expression of sex chromosome-linked genes. In placental mammals dosage compensation is achieved by inactivation of one X chromosome in female cells in a process called X chromosome inactivation (XCI). Central players in this process are the two antisense transcribed, non-coding RNAs Xist and Tsix. *Xist* expression is required to silence the X chromosome in *cis* while *Tsix* expression is involved in the down-regulation of *Xist* on the active X chromosome.
In order to study the early genetic regulation of *Xist* and *Tsix*, and to learn more about the dynamics during the onset of XCI, we created a series of reporter constructs by homologous recombination-mediated targeting in male and female murine embryonic stem (ES) cells. *Xist* and *Tsix* transcription units were replaced with sequences encoding for GFP and CHERRY, respectively, thus allowing the expression of the reporters under the endogenous promoters of these two non-coding genes. Three ES cell lines were obtained: i) Xist promoter-GFP knock-in, ii) Tsix promoter-CHERRY knock-in and iii) double knock-in on the same allele with Xist promoter-GFP and Tsix promoter-CHERRY. We also introduced CHERRY/GFP-Ezh2 fusion transgenes into these cell lines providing a direct and live read-out for PRC2 coating and heterochromatinization of the inactive X chromosome (Xi).
Differentiation of correctly targeted ES cells and expression of *Xist* and *Tsix* on the remaining wild-type allele are unperturbed. Moreover, expression of GFP and CHERRY in targeted clones appears to faithfully recapitulate the behaviour of Xist and Tsix located on the wild-type loci during the first few days of differentiation: upon differentiation, GFP is initially up-regulated until the Xist promoter on the mutant allele becomes repressed around day 3 of

differentiation because this *Xist* deletion allele is destined to become the active X chromosome (Xa). In the double knock-in lines, which allow independent tracking of Xist/Tsix, Xist is not completely silenced. CHERRY expression on the other hand is high in undifferentiated ES cells and is repressed gradually during differentiation. Initial results, however, suggest that down-regulation of the CHERRY Tsix reporter is compromised in the absence of *Xist*. CHERRY-Ezh2 fusion protein localizes to the Xi territory for a short time-window during differentiation as would be expected from earlier studies.
Live-imaging of these cell lines is feasible for extended periods of time and together with lineage tracing will yield insights into the dynamics and the interplay of *Xist* and *Tsix* in XCI. In addition, we are currently deriving mice from these ES cell lines which will enable us to follow the dynamics of *Xist* and *Tsix* expression and localization of PRC2 *in vivo* in developing embryos.

W-2354

MOSAIC TRIPLOID HUMAN EMBRYONIC STEM CELLS DERIVED FROM TRIPLONUCLEAR ZYGOTES

Ruttachuk Rungsiwiwut, Pranee Numchaisrika, Vichuda Ahnonkitpanit, Pramuan Virutamasen, Kamthorn Pruksananonda
Department of Obstetrics and Gynecology, Chulalongkorn University, Bangkok, Thailand

In general, either donated- or abnormal pronuclear formation embryos were used as the starting material for generation of human embryonic stem cells (hESCs). Previous reports demonstrated that hESCs derived from trisomic zygotes could undergo self-correction toward chromosomally normal hESCs, resulting in the diploid hESCs. Thus, these abnormal pronuclear zygotes can serve as an alternative source for deriving normal karyotype hESC lines for clinical applications.
The objective of our study was to isolate hESCs from tripronuclear zygotes in order to confirm whether the chromosomal correction could occur in the established hESCs. A total of 8 blastocysts, developed from tripronuclear zygotes were subjected to hESC isolation. Karyotypic analysis of established hESCs were performed in an early passage in order to check the chromosomal correction. The pluripotency of established hESCs were confirmed by immunostaining of the pluripotent markers, expression of the pluripotent genes by RT-PCR. Identification of the cell line was performed by analysis of DNA finger printing. The cells were allowed to spontaneously differentiate both *in vitro* and *in vivo*. In addition, hESCs were induced to undergo trophoblast differentiation by addition of 100 ng/ml of BMP-4 into the culture. The morphological changes, expression of trophoblastic genes as well as the secretion of human chorionic gonadotropin (hCG) were detected in differentiated cells.
The results of our study showed that, chromosomal correction of tripronuclear zygotes during derivation did not occur. We have successfully generated one triploid hESC line, Chula3.hES. This line carries three sets of each chromosome and shows a numerical aberration in an early passage, as demonstrated by showing the karyotype of 70 XXY, +12 and 69 XXY, +12, -15. This cell line was positively immunostained for SSEA-4, TRA-1-60, TRA-1-81 and Oct-4. RT-PCR results showed the expression of Oct-4, Nanog, SOX2, UTF, REX1, Lin28 and Nodal. This cell line differentiated into three embryonic germ layers including ectoderm, mesoderm and endoderm both *in vitro* and *in vivo*. Short tandem repeat (STR) analysis showed triple peaks in several loci that demonstrate the triploid characteristics of the Chula3.hES cell line.
After induction of trophoblast differentiation, nearly all of Chula3.hES cells flattened and enlarged prominent nuclei that resemble the early stage of trophoblast differentiation were observed. However, at Day 14, some hES-like cells still remained in the culture. The RT-PCR results showed that differentiated cells decreased the expression of Oct-4 and did not expressed Nanog and SOX2. The expression of the trophoblast marker genes Cdx2 and EOMES were increased in BMP-4 treated cells. In addition, the secretion of hCG into the culture media by BMP-4 treated cells was measured by ELISA. We found that hCG hormone was readily detected in the culture media after 7 days of differentiation and the level of hCG consistently increased over the duration of differentiation. The level of hCG measured in the culture media at Day 14 (339.4 ± 105 mIU/ml) was significantly higher than at Day 7 (5.56 ± 2.4 mIU/ml) and Day 0 (0.1 ± 0 mIU.ml) respectively, $P \leq 0.001$.

Although the chromosomal correction of triploid hESCs generated from tripronuclear zygote did not occur in the present study, this triploid hESC line will be a useful model for investigations of cell physiology, early development and the effect of chromosomal abnormalities on tumorigenicity.

W-2355

A HIGH-THROUGHPUT SCREEN TO IDENTIFY SMALL MOLECULES WHICH PROMOTES RETINAL PIGMENT EPITHELIUM DIFFERENTIATION FROM HUMAN PLURIPOTENT STEM CELLS.

Julien Maruotti, Karl Wahlin, Valentin Sluch, Catherine Kim, Donald J. Zack
Johns Hopkins Univ, Baltimore, MD, United States

Age-related macular degeneration (AMD) is the most common cause of irreversible visual loss in the elderly in the Western world. It is a devastating disease of the retina that can lead to central blindness. It affects the retinal pigment epithelium (RPE), the layer of cells that surrounds and nourishes the neurosensory retina. RPE dysfunction cells can lead to photoreceptor dysfunction and cell death, and subsequent vision loss.
Currently, there are few if any available options to treat or replace diseased RPE cells. Cell-based transplantation strategies offer the promise of being able to restore RPE cells, thus potentially limiting vision loss. Therefore, establishing an abundant and quality source of donor cells is of utmost importance. Human pluripotent stem cells (hPSCs) may prove suitable for this purpose: significant advances have recently been made in inducing the differentiation of hPSCs toward an RPE-like cell fate and a Phase I clinical trial using such differentiated cells is currently ongoing, and several others are being planned. Nevertheless, the length and efficiency of RPE generation from hPSCs are still not optimal. We therefore sought to develop a high-throughput screen aimed at finding small molecules that could improve RPE differentiation in terms of efficiency and time course.
hPSC were maintained by clonal propagation. Using automated liquid handlers, they were differentiated in 384-well format. In DMSO treated plates, uniformly differentiated cultures were observed. In addition, high-throughput quantitative real-time PCR for key RPE markers indicated similar expression levels across the plate. hPSC can now be differentiated in the presence of compounds from small molecule libraries, and HTS qPCR used to identify hits upregulating key RPE markers.
In conclusion, we have developed a HTS qPCR approach to identify molecules that promote RPE differentiation from hPSC, and a screen to identify differentiation promoting small molecules is underway.

HIRA IN REGULATION OF RUNX1

Debasree Dutta
Cancer Research Program, Rajiv Gandhi Centre for Biotechnology, Thiruvananthapuram, India

Hemogenic endothelium (HE) encompasses the population of endothelial cells having hemogenic potential. HE through an endothelial-to-hematopoietic transition generates hematopoietic stem cells (HSCs). HSCs are the most desirable source of therapeutic cells for blood diseases. Earlier studies have shown that a unique balance of the transcription factors Hoxa3 (Homeobox protein Hoxa3) and Runx1 (Runt-related transcription factor 1) drives the differentiation towards endothelial or hematopoietic progenitors respectively. However, the molecular mechanisms that regulate the chromatin domain and thereby dictate the context specific expression of these transcription factors is poorly understood. Recently, Histone chaperone mediated endothelial-gene specific regulation has been reported. So, we hypothesized that in particular, Histone chaperone HIRA might be critical for the balancing of this endothelial to hematopoietic transition. So, in this study, we investigated the role of histone chaperone HIRA in modulating the function of RUNX1, the crucial regulator of HSCs generation from HE. For that, we analyzed the classical model of embryonic stem cell (ESC) differentiation in culture. Most of the evidences till date indicate that the events associated with the establishment of hematopoietic or endothelial lineage in embryoid bodies (EBs) generated from ESCs, replicate the incidences in early yolk sacs. During differentiation of mESCs towards EBs, both Runx1 and Hoxa3 expression is upregulated by day 3 whereas the ectodermal marker Nestin gets induced by day 5.

However, Runx1 is expressed ~20 fold higher than that of Hoxa3. To analyze the role of Hira, we differentiated HIRA null ESCs towards the formation of EBs. The expression of both Hoxa3 and Nestin were induced by day 3. However, EBs from HIRA null ESCs demonstrated an increase of ~3 fold expression of Hoxa3 as well as Nestin than that of EBs from control ESCs. This further establishes the previous findings that loss of HIRA is associated with increased availability of free histones that influence the induced differentiation of ESCs. Intriguingly, the expression of Runx1 was almost abrogated in EBs from null cells within day 3. We failed to differentiate these HIRA null ESCs towards HE. As, HIRA is associated with H3.3 variant of Histone H3, so Hira mediated incorporation of Histone H3.3 at the Runx1 locus might be essential to regulate the expression of Runx1 during differentiation. While RUNX1 has been implicated in coordinating vascular morphogenesis like endothelial tube formation and sprouting, so it is tempting to speculate that the fatal vascular defects associated with HIRA null mice might develop from the abrogation of RUNX1 expression.

W-2357

DIFFERENTIAL EXPRESSION OF 5HT RECEPTORS IN HESCS AND HESC DERIVED 5HT NEURONS

Athina Samara[1], Susanne Strom[2], Joel C. Glover[3]

[1]Physiology, University of Oslo, Oslo, Norway, [2]Norwegian Centre for Stem Cell Research, Oslo, Norway, [3]University of Oslo & Norwegian Centre for Stem Cell Research, Oslo, Norway

Serotonin (5-HT) is a major neuromodulatory neurotransmitter in nearly all animal species. In mammals, the physiological effects of serotonin range from regulation of subcortical sensory and motor systems, such as pain and the central pattern generator for locomotion, to regulation of higher cognitive functions, such as mood, awareness, consciousness and sleep. Deregulation of serotonin is implicated in a myriad of neuropathologies, including pain syndromes such as migraine, motor, sleep, eating and mood disorders.
Serotonergic neurons derived from human embryonic stem cells (hESCs) would provide a useful platform for standardized and quantitative studies of differentiation, synaptic function and pathogenic mechanisms.
The 5-HTRs comprise 6 families of GPCRs (5-HT1, 2, 4, 5, 6, and 7) and one ligand-gated ion channel (5-HT3). Among these, the 5-HT2A receptor is one of the best studied and its function is associated with cognition, mood, thermoregulation, sleep, cardiovascular function, and muscle contraction.
Currently, very few 5HTR ligands are subtype-selective and development of novel, more specific 5HT antagonists is needed. Pharmaceutical R&D has mainly been compromised by a lack of experimental platforms.
OBJECTIVE
To assess the expression of 5-HTRs in hESCs and hESC-derived 5-HT neurons.
METHODS
Cell culture and neuronal differentiation: In brief, H9 and HS360 hES cell lines were cultured on human foreskin fibroblasts in 20% KO-SR in KO-DMEM supplemented with bFGF.
Neural differentiation was induced by forming embryoid bodies (EBs). EBs were plated on a mixture of matrix proteins and a 6-week protocol was followed wherein cultures were supplemented with combinations of cAMP, SHH, FGF4, FGF8, BDNF, AA, NT3 and NT4 to attain serotonergic differentiation.
Real time RT-PCR was performed to asess the expression of 5-HTRs.
RESULTS
Transcripts of all 5-HT receptor subtypes are present in hESCs. All subtypes are upregulated from 30-fold to 30000-fold after directed differentiation to 5-HT neurons. By assessing expression in different lines derived from male and female embryos, gender differences in the expression of several subtypes were found in both hESCs and differentiated 5-HT neurons.
DISCUSSION
Serotonergic neurons derived from hESCs provide a useful platform for standardized and quantitative studies of pharmacological agents. Characterization of 5-HTR expression profiles is important for developing appropriate tools for 5-HTR subtype-specific assays.

SEX SPECIFIC GENE EXPRESSION IN HUMAN EMBRYONIC STEM CELLS

Daniel Ronen, Vadim Gercenstein, Nissim Benvenisty
Hebrew Univ Jerusalem, Jerusalem, Israel

Males and females demonstrate a large variety of sex dimorphic traits most of which result from hormonal differences. However, differences between male and female embryos initiate during early development, before hormonal influence begins, suggesting the presence of genetically driven sexual dimorphisms. In order to specifically study the contribution of the Y chromosome at the earliest stages of development we compared the gene expression profiles of male and X-inactivated female human pluripotent stem cells. This approach allowed us to detect that the sex determining gene SRY is the only Y specific gene expressed in human male embryonic stem cells. Furthermore reprogramming of male somatic cells to induced pluripotent stem cells (iPSc) resulted in activation of SRY. SRYs participation in the pluripotent state was confirmed by the activation of SRY in iPSc derived from XX+SRY sex reversal patients and the activation of a reporter gene fused to the promoter region of SRY, transfected into female ES cells. In addition sorting of ES cells based on TRA1-60 expression confirmed TRA1-60 positive male cells express SRY. In order to understand the consequence of SRY expression in male pluripotent cells we compared the gene expression profile of multiple male and female samples detecting more than two hundred differential autosomal genes. Further analysis of these genes revealed more than 80 genes containing a putative SRY binding site in their promoter. Functional annotation analysis further discovered these genes are involved in developmental regulation and steroid metabolism pathways. We confirmed the differential expression of the steroid metabolism genes ABCA1 and HSD17B12 by qPCR. As estrogen exposure results in increased proliferation of ES and other cells we tock advantage of the ability of HSD17B12 to convert the inactive estrogen precursor estron (E1) to the biologically active estradiol (estrogen, E2) in order to elucidate the functional role of the differential gene expression. Exposing ES cells to estradiol (estrogen, E2) resulted in increased proliferation of both male and female cells. While exposing ES cells to estron (E1) resulted in increased proliferation of female cells only in accordance with the increased expression of HSD17B12. Cell cycle analysis revealed an increased fraction of female cells in G2/M following E1 exposure, while apoptosis analysis showed no difference between males and females. Stable expression of SRY in female ES cells resulted in converting both the estrogen involved gene expression and the response to E1 similar to male cells. In addition, we confirmed the differential expression of ID2 and CTCFL genes which are involved in regulation of muscle, lymphoid, neuronal and spermatocye differentiation all of which show dimorphic phenotypes between the sexes in later developmental stages.
Based on these results we propose that the presence of the Y chromosome and specifically SRY may drive sex specific differences in growth and differentiation properties of pluripotent stem cells.

DIRECTING SKELETAL MUSCLE PROGENITOR CELL FATE FROM HUMAN PLURIPOTENT STEM CELLS

Richard Swan[1], Thomas Dial[2], Zheng Luo[3], Shuang Hou[3], Jinliang Peng[3], Sean Sherman[2], Rebecca Andersen[2], Cindy Malone[1], Hsian-Rong Tseng[3], April Pyle[2]
[1]Biology, California State University Northridge, Northridge, CA, United States, [A]Department of Microbiology, Immunology, & Molecular Genetics, [B]Department of Molecular and Medical Pharmacology, [2]University of California Los Angeles, Los Angeles, CA, United States

Human pluripotent stem cells (hPSCs) offer enormous potential for studying human development, for pre-clinical screening and regenerative therapies. Muscle wasting and weakness are common to many disease states and conditions including aging, cachexia and muscular dystrophies. The focus of this study is to determine how to direct skeletal muscle differentiation from hPSCs for use in muscle disorders. The research aims of this project are to determine the best approach for directing skeletal muscle fate from hPSCs without the need for genetic manipulation. We will carry out these studies using two approaches. In the first approach, we evaluate the role of somatic mesoderm patterning signals responsible for specifying myogenesis in the developing embryo towards directing muscle

cells from hPSCs. Second we will determine the myogenic potential of skeletal muscle progenitor cells (SMPCs) using a novel-reprogramming platform.
In the first approach, we have evaluated the timing and growth factor cues required for directing SMPC specification. The SMPCs were analyzed by qPCR for known SMPC markers including PAX3, PAX7 and PAX6 as a neuronal marker up to 30 days. In this manner we have seen increased SMPC but decreased expression of neuronal markers under conditions favoring SMPC specification.
In the second approach, we will determine if overxpression using a novel non-integrating/non-viral gene delivery platform can directly reprogram hPSCs towards muscle fate. The novel reprogramming system leverages the power of a self-assembly strategy using nanoparticles and a nanostructured substrate with built in molecular recognition tags that allow for local enrichment, highly efficient and on demand packaging and delivery of numerous biomolecules to cells. These experiments will provide a novel approach for directing SMPCs and will determine the myogenic differences between directly reprogrammed somatic cells or differentiated hPSCs. Thus far we have shown that we can overexpress the SMPC regulatory Pax7 and Pax3 transcription factors within the hESC cells using this platform. Ongoing studies are evaluating the in vitro and in vivo muscle potential of the directly reprogrammed cells. Understanding the cellular cues required for development of SMPCs will have great impact for use in regenerative medicine applications.

W-2362

REVEALING SPATIAL PATTERNING IN HUMAN EMBRYONIC STEM CELL DIFFERENTIATION USING MICROPATTERNED CONTROL OF COLONY ARCHITECTURE.

Aryeh Warmflash, Benoit Sorre, Eric D. Siggia, **Ali H. Brivanlou**
The Rockefeller University, New York, NY, United States

Human embryonic stem cells (hESCs) provide a window into human development but the use of these cells to study spatial patterning and axis formation has been hampered by the fact that most differentiation protocols are designed to yield homogeneous populations of cells or produce a spatially disorganized heterogeneous combination of fates. Here, we control the size and shape of hESC colonies with micropatterning technology and use this platform to analyze spatial aspects of signaling and fate acquisition both in the state of pluripotency and during differentiation. We show that cells grown in pluripotent conditions have variable levels of both signaling effectors and key pluripotency transcription factors as a result of their ability to sense the edge of the colony. Colonies grown in micropatterned culture and differentiated with BMP4 ligand produced cells from all three germ layers in spatially ordered patterns resembling those found in mammalian embryos. These patterns are highly reproducible with nearly every colony yielding identical results. We show that these patterns depend on induced activin/nodal signaling and that they form from the outside of the colony inwards. Taken together, our results establish micropatterned cell culture as a powerful system for studying cellular communication and spatial patterning during human development.

W-2363

THE C-YES TYROSINE KINASE IS A POTENT SUPPRESSOR OF ES CELL DIFFERENTIATION AND ANTAGONIZES THE ACTION OF ITS CLOSEST PHYLOGENETIC RELATIVE, C-SRC

Xiong Zhang, Malcolm A. Meyn III, Thomas E. Smithgall
Microbiology and Molecular Genetics, University of Pittsburgh, Pittsburgh, PA, United States

ES cells are derived from the inner cell mass of the blastocyst stage embryo and are characterized by self-renewal and pluripotency. Previous work has implicated the Src family of non-receptor protein-tyrosine kinases in the self-renewal and differentiation of mouse ES cells. At least seven members of the Src family are expressed in ES cells, with dynamic expression and activity changes during ES cell differentiation, implying distinct functions in the control of developmental fate. In this study, we used ES cells to test the hypothesis that individual members of this kinase family act in biological opposition despite their strong homology. Specifically, we examined c-Src and its

closest phylogenetic relative c-Yes for our study, because they have been independently linked to differentiation and self-renewal in previous studies. Mouse ES cell populations were generated that express low levels of wild-type, active and kinase-dead forms of c-Yes. All c-Yes transduced ES cell populations were indistinguishable from cultures of parental cells in terms of colony morphology and pluripotency marker expression. However, cultures expressing wild-type and active c-Yes had abnormal embryoid body (EB) differentiation and retained the expression of pluripotency markers. In contrast, ES cells expressing kinase dead c-Yes formed EBs indistinguishable from the controls, demonstrating that the c-Yes anti-differentiation signal requires kinase activity. To explore the interplay of c-Src and c-Yes in ES cell renewal and differentiation, we employed a chemical genetics approach previously applied to c-Src in this system. We engineered c-Src and c-Yes mutants that are resistant to A-419259, a potent inhibitor of Src-family kinases. Previous studies have shown that A-419259 treatment blocks all Src-family kinase activity in ES cells, preventing differentiation while maintaining pluripotency. Expression of inhibitor-resistant c-Src rescues the A-419259 differentiation block, resulting in primitive ectoderm-like cells. Remarkably, ES cells co-expressing the resistant c-Src and c-Yes kinases failed to differentiate in the presence of the inhibitor, demonstrating that the c-Yes signal is dominant. Our findings show that c-Yes kinase is a potent suppressor of differentiation in ES cells. We also demonstrate, for the first time, that even very closely related kinases such as c-Src and c-Yes have unique and opposing functions in the same cell type. These results suggest that selective inhibitors of c-Src vs. c-Yes activity may allow more precise pharmacological manipulation of ES cell fate.

W-2365

A RAPID, COLUMN-FREE IMMUNOMAGNETIC SEPARATION PROCEDURE FOR THE ISOLATION OF CXCR4-POSITIVE DEFINITIVE ENDODERM FROM HUMAN PLURIPOTENT STEM CELLS

Michael J. Riedel, Vesna Posarac, Yvonne Luu, Maureen Fairhurst, Karina McQueen, Terry E. Thomas, Allen C. Eaves, Sharon A. Louis
STEMCELL Technologies Inc., Vancouver, BC, Canada

The efficient generation of mature cell types from human pluripotent stem cells (hPSCs) may require a combination of specialized media along with stage-specific cell purification strategies to further enrich for desired target cells. The initial step in the differentiation of endoderm cells from hPSCs, including those of the pancreas, liver, lung, and gut, is the formation of definitive endoderm (DE). Molecular characterization of hPSC-derived DE reveals high levels of expression of CXCR4, a cell surface chemokine receptor. The expression of additional DE markers is highly enriched within $CXCR4^+$-purified cell populations. While CXCR4 is also detected on hPSC-derived mesoderm cells, most state-of-the-art DE differentiation protocols yield minimal mesoderm cell contamination. Thus immunomagnetic purification of DE cells based on CXCR4 expression may be a plausible strategy to enrich for these cells within differentiating cultures. With increased interest in the use of patient-specific human induced pluripotent stem cells (hiPSCs) for disease modeling, drug screening, and cell-based therapies, methods for efficient DE differentiation across many hiPSC lines will be required. To address the need in the field for improved and highly efficient cell culture and purification strategies for obtaining hPSC-derived DE, we developed a rapid immunomagnetic column-free method (EasySep™) for purification of $CXCR4^+$ cells derived from hPSCs.
Human embryonic stem cells (H9) or hiPSCs (WLS-4D1) were maintained under defined and feeder-free conditions in mTeSR™1 prior to differentiation toward DE. The results showed that starting cells samples with an average frequency of 76.8 ± 4.4% (n = 9) $CXCR4^+$ cells could be purified to 92.8 ± 2.0% $CXCR4^+$ cells with excellent cell recoveries (90.2 ± 7.1%). Using STEMdiff™ Definitive Endoderm Basal Medium during separation improved cell recovery and allowed enriched DE cells to be maintained continuously in a serum-free environment both in culture and subsequently during the immunomagnetic selection procedure. Purified DE retained the ability to be continued in culture and differentiated towards more specified endoderm cell types.
The propensity for DE differentiation in hPSC lines maintained or differentiated using alternative culture methods can vary significantly. The EasySep™ CXCR4 positive selection strategy reported here offers a rapid and simple-to-use protocol for the isolation of highly pure populations of hPSC-derived definitive endoderm.

W-2366

THE DYNAMICS OF OCT4A AND ITS PSEUDOGENES EXPRESSION DURING DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS

Mojca Jez[1], Sakthikumar Ambady[2], Matija Veber[3], Tanja Dominko[2], Primoz Rozman[1]
[1]Blood Transfusion Centre of Slovenia, Ljubljana, Slovenia, [2]Worcester Polytechnic Institute, Worcester, MA, United States, [3]Educell Ltd., Ljubljana, Slovenia

OCT4A transcription factor is one of the main regulators of pluripotency. It is expressed in embryonic stem cells (ES cells), embryonic carcinoma cells (EC cells) and primordial germ cells. In recent years, the expression of OCT4 has also been detected in various tumors, normal adult tissues (bone marrow, umbilical cord and peripheral blood), and even in certain adult cell lines. The OCT4 gene has three alternative transcripts: OCT4A, OCT4B and OCT4B1, which are translated into four different protein isoforms: OCT4A, OCT4B-265, OCT4B-190, and OCT4B-164. There are also at least six known OCT4 pseudogenes scattered through the genome (PG1 to PG6). Recent publications show that contrary to previous expectations some of these pseudogenes are transcribed and possibly even translated.
The aim of this study was to determine which pseudogenes are expressed in ES cells and how their expression changes during differentiation. We focused on PG1, PG3 and PG4 because of their high sequence identity to embryonic transcript.
ES cells (line H9) were differentiated in two-step differentiation protocol in the medium containing retinoic acid. For the first 5 days cells were cultured as embryoid bodies. After five days embryoid bodies were plated on tissue culture plates and differentiated for 62 days as an attached culture. Every few days RNA samples were isolated and tested for the expression of OCT4 pseudogenes. The distinction between embryonic OCT4A transcript and all its pseudogenes and between PG1, PG3 and PG4 was achieved by specific restriction analysis of RT-PCR product. The restriction method is based on the presence/absence of restriction sites resulting from SNP (single nucleotide polymorphism) in various transcripts - each SNP is specific for each pseudogene. PCR amplicons were also cloned and sequenced to confirm the accuracy of restriction method.
Undifferentiated embryonic stem cells and EC cells (NTERA and NCCIT) did not express any of the OCT4 pseudogenes. During differentiation, the expression of pluripotency markers OCT4A, SOX2, NANOG and CRIPTO-1 was down regulated and expression of pseudogenes was turned on and they were exclusively expressed in differentiated cells.
Our work is the first report about the expression of OCT4A pseudogenes 1, 3 and 4 during ES cells differentiation. Our results show that during differentiation of stem cells there is a developmentally regulated balance between the expression of embryonic genes and pseudogenes. The switch between one transcription pattern to the other depends on differentiation status of the cells. Since pseudogenes were expressed only in mature somatic cells we propose that the expression of pseudogenes can be used as a novel marker of cell differentiation status. Our data also indicates that it is necessary to critically evaluate existing published conclusions on the expression of OCT4A in different cell types, because pseudogene expression can lead to false positive results of molecular analysis.

W-2367

PROSTAGLANDIN D2 DP1 RECEPTOR MEDIATED TOXICITY IN ALS

Sophie de Boer, Evangelos Kiskinis, Kathryn Koszka, Kevin Eggan
Harvard University, Cambridge, MA, United States

Stem cells are currently used to model a wide variety of diseases, to reveal underlying disease mechanisms and eventually facilitate drug discovery. Here, for the first time, we are able to validate a stem cell based disease model *in vivo*.
We use a previously established stem cell based assay to model the neurodegenerative disease, amyotrophic lateral sclerosis (ALS), *in vitro*. Human embryonic stem cell derived motor neurons are co-cultured with primary mouse

glia of different genotypes. Motor neurons cultured onto mutant glia show a non-cell autonomous neurodegenerative effect. This effect, is specific to motor neurons and is mediated through secreted diffusible factor(s), which induce an inflammatory response.
Expression profiles of mutant glia display an upregulation of inflammatory markers, including the Prostaglandin D2 receptor DP1 (DP1). In the co-cultures, the DP1 antagonist, BW A868C protects motor neurons from the toxic effect of mutant glia. In addition, when the DP1 agonist, BW 245C, is added to wild type co-cultures a toxic effect, similar to the one produced by mutant glia is observed. Both the DP1 antagonist and agonist work solely on the glia cells, since a pre-treatment with these compounds on the glia alone, added and removed before the motor neurons are plated, is sufficient to induce a protective or a toxic effect respectively.
Since the DP1 receptor is expressed in a variety of cell types, we went on to identify the cell type that is responsible for these effects in the glia culture. We designed a modified co-culture system, in which microglia from different genotypes are spiked into the co-cultures. Mutant spiked in microglia have a toxic effect on the motor neurons, similar to the effect of the mutant glia. When these microglia were pre-treated with the DP1 antagonist, no toxic effect was observed. Indicating a direct interaction between microglia and the compound.
Furthermore, when glia derived from DP1-/- mice, carrying the ALS mutation, were co-cultured no motor neuron degeneration was observed. Additionally, an *in vivo* survival study of these mice showed a significant increase in lifespan compared to the DP1+/+ mice carrying the ALS mutation.
Collectively, our results propose for a model of ALS in which non-cell autonomous motor neuron toxicity is mediated through the Prostaglandin D2 DP1 receptor on microglia. More generally, our results validate a stem cell based disease model *in vivo* for the first time, underscoring the clinical relevance of these models.

W-2368

MESENCHYMAL STEM CELLS ENABLE ANGIOGENIC FUNCTION IN EMBRYONIC STEM CELL-DERIVED VASCULAR PROGENITOR CELLS

Lisa M. McGinley, Robert M. Nerem
Parker H. Petit Institute for Bioengineering & Bioscience, Georgia Institute of Technology, Atlanta, GA, United States

The ability to modulate vasculogenesis and angiogenesis could allow for the development of therapies for numerous physiological and pathological states associated with vessel formation, such as wound healing, tumor growth and ischemic disease. Such techniques can also be applied to the field of regenerative medicine where the development of vascular supply systems is necessary for the functionality of engineered tissues. In order to generate microvascular networks *in vitro*, a readily available and expandable source of endothelial cells capable of vessel formation is required. The derivation of endothelial cells (EC) from embryonic stem cells (ESC) offers a potential source of vascular cells and it has been suggested that bone marrow derived mesenchymal stem cells (MSCs) may function as pericytes and play an important role in regulating vascular morphogenesis. The present study aims to create mouse ESC-derived microvascular networks and investigate the interactions between MSCs and vascular progenitor cells in the context of angiogenesis.
For endothelial differentiation, mouse R1 ESC were seeded on ECM (either collagen type IV or fibronectin) for 2-5 days. Two differentiated cell populations were collected for experiments – mixed vascular progenitors (VPC) with no selection and FLK1 VPC isolated by FACS for FLK1/VEGFR2. Both cell populations were characterized by flow cytometry analysis for endothelial and smooth muscle cell markers. Next, co-culture experiments were performed to assess the effect of MSCs on angiogenesis-relevant behavior such as migration, proliferation and vessel-like structure formation in Matrigel™.
Migratory capacity of both mixed VPC and FLK1 VPC was significantly increased in response to MSCs. Increased cell number and viability was also observed when both VPC populations were co-cultured with MSCs, as well as greater proliferation. In Matrigel™, mixed VPCs alone, FLK1 VPCs alone or MSCs alone did not form networks. However, formation of microvascular-like structures did occur in the presence of MSCs. - both tubule length and number of tubule junctions was significantly increased in both progenitor cell populations. This effect was observed to be both time and dose dependent. Addition of MSCs to mixed VPCs increased network formation when both cell types were present in equal numbers. For FLK1 VPC, MSC addition after time zero in ratios of 1:1 and 2:1 (FLK1 VPC:MSC)

resulted in network formation. Further optimization of network stability in terms of MSC dose and time of addition is currently underway.
These results suggest that MSCs play an important role in angiogenesis and may enable VPC function, indicative of a pericyte role. Furthermore, terminal endothelial differentiation of ESCs may not be strictly necessary for *in vitro* microvascular network formation. In conclusion, these data may have potential implications for sourcing of functional vascular cells applicable to tissue engineering and cell therapeutics, warranting further study in the area.

W-2371

APOBEC3G INFLUENCES HEMATOPOIETIC LINEAGE COMMITMENT IN CELLS DERIVED FROM hESC

Yesai S. Fstkchyan[1], Christopher C. Nixon[2], Manik Harutyunyan[2], Cindy Malone[3], Zoran Galic[4], Jerome Zack[2]
[1]Biology, California State University Northridge, Northridge, CA, United States, [2]Department of Microbiology, Immunology, & Molecular Genetics, University of California, Los Angeles, Los Angeles, CA, United States, [3]Biology, California State University, Northridge, Northridge, CA, United States, [4]Division of Hematology and Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States

Apolipoprotein B mRNA editing enzyme catalytic polypeptide like-3 G (APOBEC3G) is a member of a family of cytosine deaminases that includes activiation induced deaminase (AID), the enzyme responsible for somatic hypermutation in B cells. While APOBEC3G (A3G) is best known for its activity in restricting both retroviral infection and the mobility of genomic retrotransposable elements, there is mounting evidence that A3G possesses a far more involved role in the cell. A3G has been localized to P-bodies, subcellular foci of mRNA editing and microRNA activity and has been found to directly influence specific microRNA activity. The Broad Institute Differentiation Map (dMap) is a collection of microarray data that quantifies levels of gene expression in hematopoietic cells throughout their development. According to dMap, levels of A3G expression fluctuate tremendously through the process of hematopoiesis. This is inconsistent with a purely antiretroviral factor. We believe that A3G influences human hematopoietic lineage commitment.
Preliminary analysis by quantitative real time polymerase chain reaction (qRT-RTPCR) to analyze A3G expression at the RNA level indicates very low levels of A3G RNA in hESC but a significant rise when hESC differentiation is induced by embryoid bodies (EB). Furthermore, A3G levels are relatively hight in HSC. Together, these data suggest a role for A3G in the earliest stages of human hematopoiesis. While there is evidence that suggests A3G has a role in intermediate hematopoieitic lineage commitment, it is unclear how A3G might influence the development to HSC from embryonic stem cells (hESC). We therefore asked whether A3G plays a role in the early development of hESC into HSC.
We have successfully introduced A3G over-expression and anti-A3G shRNA constructs via lentiviral infection in H1 hESC without any overt toxicity. Stable transduction was confirmed by 4 weeks of puromycin selection and expression of our reporter gene, LNGFR. There is no apparent change in self-renewal or proliferation ability of hESC's when transduced. Transduced cells were differentiated using EB method cultured in differentiation media. EB's were differentiated for 14 days and harvested on day 15. Flow analysis of EB harvest reveals that cells with over-expression and knockdown of A3G are able to differentiate; both groups give rise to 37% CD45+ cells in similar numbers to that of the scramble control group, indicating cells with hematopoietic potential. About 2-7% of the CD45+ cell population also express CD34. Furthermore, whole EB harvests were platted into methycellulose and scored 14 days later. Knockdown of A3G showed a serve reduction of erythroid colony forming units when compared to the control group. Over expression of A3G inhibits colony formation. This is consistent with previous results where the same constructs were introduced to CD34+ HSC's from fetal liver. Specifically, when A3G expression is diminished by introduction of a lentiviral vector expressing shRNA against A3G in HSC's and assayed by CFU assays, lineage commitment is skewed in favor of myeloid lineages. In contrast, there is a 50% deficit in erythroid and megakaryocyte lineages. When A3G is over-expressed in a similar fashion, hematopoiesis is impaired. Even though further analysis is needed, preliminary data suggests that A3G plays a role in early hematopoietic develop and has no apparent role in hESC differentiation to hematopoietic progenitors.

APOPTOTIC MECHANISM IN HUMAN EMBRYONIC STEM CELLS

Kiyoko Miyata[1], Carla M. Koehler[2], Michael A. Teitell[1]
[A]Department of Pathology and Laboratory Medicine, [B]Department of Chemistry and Biochemistry, [1]University of California, Los Angeles, Los Angeles, CA, United States

Human embryonic stem (hES) cells can differentiate into all three embryonic germ layers and may also be useful for supporting postnatal tissue renewal. They display an abbreviated cell cycle with a very short G1 phase. This acceleration in cell cycle time increases the importance for hES cells to engage mechanisms that protect genomic integrity to avoid proliferative defects that may cause aberrant development or cancer. Apoptosis is an available mechanism for maintaining genomic stability for an organism following DNA or other forms of cellular damage. Currently, it remains largely unknown what apoptotic mechanisms become engaged by hES cells under which cellular insults and also how these mechanisms are affected by hES cell differentiation. Here, we induced apoptosis in hES cells, and in hES cells induced to differentiate with retinoic acid (RA), by exposure to three different agents (actinomycin D, etoposide, and tunicamycin) that trigger distinct apoptotic pathways. We demonstrate that (a) hES cells respond more rapidly to all three insults than do RA-differentiated hES cells; (b) Bax activation and mitochondrial intermembrane space protein release, which occurs early during apoptosis, occurs more rapidly in hES cells than in RA-differentiated hES cells; and (c) cytosolic factor(s) are involved in hES cell hypersensitivity to these forms of apoptosis induction. Taken together, there is a mechanism(s) that primes hES cells for rapid death by apoptosis, which would prevent the propagation of unrepaired mutations or cellular alterations during the early critical stages of embryonic development.

WNT5A MEDIATES CHONDROGENIC DIFFERENTIATION OF HUMAN ESC-DERIVED PROGENITORS INTO ARTICULAR-LIKE CHONDROCYTES

Jason D. Gibson, Rosa M. Guzzo, Hicham Drissi
Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, United States

Cartilage defects often target young and middle-aged populations following traumatic joint injuries and if left untreated, damage from these injuries can lead to osteoarthritis. Treatment modalities vary depending on the severity of the cartilage damage, as well as other patient-specific factors. For large cartilage defects the gold-standard procedure is autologous cell transplantation. However, this procedure often results in the formation of fibrocartilage rather than articular-like cartilage, and the resulting hypertrophic chondrocytes in this fibrocartilage environment can produce proteases which induce matrix degradation. Thus, controlling the differentiation of progenitor cells into articular-like chondrocytes using a single growth factor would be ideal to devise a cell-based strategy to repair large articular cartilage damage. Furthermore, considering the limited regenerative capacity of adult stem cells, human embryonic stem cells (hESC) may provide an ideal cell source for more effective cell-based cartilage regeneration. Using genetic models we previously established a role for non-canonical Wnt5a signaling in the specification of chondrogenesis and inhibition of chondrocyte maturation toward hypertrophy during mouse limb development. Based on these findings, we hypothesized that Wnt5a can induce the progression of hESC-derived progenitors toward the chondrogenic lineage while inhibiting their terminal maturation. We have recently examined the chondrogenic potential of Wnt5a on the differentiation of hESCs, and the timing of Wnt5a signaling for controlling the progression of differentiating cartilage cells toward hypertrophy. Using a standard cell culture derivation technique, we induced hESCs to become mesenchymal stem cell (MSC)-like progenitors as characterized by their cell-surface expression profiles. We found that the expression profile of common MSC markers was similar between hESC-derived progenitors and de-differentiated human articular chondrocytes. We also established the multipotential ability of these hESC-derived MSC-like cells to differentiate into chondrogenic, adipogenic and osteogenic cell lineages. Chondrogenic induction of hESC-derived MSCs was achieved using high-density pellet cultures,

and the temporal effects of Wnt5a treatment in these cultures was compared to that of BMP-2. We found that while BMP-2 was able to induce differentiation of these cells into the chondrogenic lineage it also induced their terminal maturation to hypertrophy. In contrast, Wnt5a induced chondrogenic differentiation of these cells while inhibiting their terminal maturation. These effects are found to be enhanced in the hESC-derived MSC-like progenitors compared to that of the somatic human articular chondrocytes. Using low-density gene arrays, we confirmed the temporal progression of the multipotent cell populations towards a chondrogenic phenotypic in response to Wnt5a, and we established that Wnt5a not only maintained chondrogenesis while inhibiting chondrocyte hypertrophy in hESC-derived progenitors, but also induced markers of articular cartilage matrix. Together, the data indicates that non-canonical Wnt5a signaling is able to control the differentiation of hESC-derived chondroprogenitors into an articular chondrocyte-like phenotype in vitro. Experiments are currently underway to examine these effects in a translational model of cartilage repair.

GENERATION OF BASAL FOREBRAIN AND MIDBRAIN ASTROCYTES FROM HUMAN PLURIPOTENT STEM CELLS

Federica Rinaldi, Lucy Crompton, Jennifer Badger, Maeve Caldwell
School of clinical science, Bristol university, Bristol, United Kingdom

Astrocytes are the most abundant cells in the brain and they provide trophic and metabolic support for neurons, as well as participating in crucial aspects of brain development and physiology. Historically considered as a passive and homogeneous cell, however more recently this specific type of glial cell can be classified into sub-categories according to their morphology, function, electrical proprieties and transcriptome. Different types of astrocytes are confined to certain brain regions, which clearly indicates a requirement for regional astrocytic support of local neurons and surrounding tissues. In this study we developed and validated a protocol for the differentiation of brain regional-specific astrocytes from human pluripotent stem cells including embryonic (hESCs) and induced pluripotent stem cells (iPSCs). These astrocytes will be useful to further elucidate mechanisms of developmental and neurodegenerative disease. Of particular interest is their role in regionally restricted neurodegenerative disorders, such as Alzheimer and Parkinson's diseases, which were previously exclusively considered as neuronal disorders. We have faithfully recapitulated in vivo neurogenesis using a three-stage protocol in non-adherent conditions, which allows the generation of neurons first and then of astrocytes. We use RNA and protein analysis to characterize the transition of hESCs and hIPSCs from multipotent to neural progenitor cells, and to more restricted astroglial progenitors. Ultimately, mimicking morphogen gradients occurring during neurogenesis in vivo, we successfully differentiate astrocytes with restricted regional identity, specifically basal forebrain and midbrain phenotypes. Our protocol has an estimable value for studying neurodegenerative disorders affecting a particular brain region as occurs in two of the most common neurodegenerative diseases such as Alzheimer's and Parkinson's diseases.

W-2375

INDUCIBLE PLURIPOTENT STEM CELLS AS A TOOL IN ARTICULAR CARTILAGE REGENERATION

Wiktoria M. Suchorska[1], Tomasz Trzeciak[2], Jarosław Pawlicz[2], Magdalena Richter[2]
[1]*Medical Physics, Radiobiology Lab, Greater Poland Cancer Centre, Poznan, Poland,* [2]*and Clinics Orthopaedics and Traumatology, University of Medical Science, Poznan, Poland*

The main objective of the study was to understand the molecular mechanisms and signal transduction pathways involved in the differentiation process of the stem cells (embryonic human stem cells - hES, and induced pluripotent stem cells - IPS) into chondrocytes.
Specific objectives include:
1.Analysis of the molecular mechanisms involved in differentiation hES cells, and IPS cells into chondrocytes by analysis of global gene expression profiles at various stages of cell differentiation
2.Comparison of the mechanisms and signal transduction pathways involved in differentiation process of hES, and IPS cells to chondrocytes

3.Multidimensional comparative analysis in vitro of mature chondrocytes differentiated from both hES, and IPS cells
4.Demonstration the functionality of the hES, and IPS cells-derived chondrocytes in the regeneration of damaged articular cartilage in vivo in an animal experimental model
Since 2010, in collaboration with the Laboratory of Gene Therapy, headed by Dr. M. Wiznerowicz we perform the research project, which is successfully used a protocol based on this year's Nobel Prize winning Takahashi and Yamanaka's experience of introducing into the genome cells four transcription factors: Oct3/4, Klf4, Sox2 and cMyc using a viral vector. The results, which we obtained, confirm the possibility of maintaining in vitro full-featured IPS cells. In addition, we have established a line of human embryonic stem cells (hES). Up to the date it was proved that hES have the capacity to differentiate directly toward chondrocytes under defined cell culture conditions. During this process we controlled the morphology of the cells, and the level of gene expression typical for embryonic cells (OCT4, SOX2, NANOG), for mesoendoderm (MIXL1), for mesoderm (PDGFRbetha), for endoderm (SOX17, GATA4) and for mature chondrocytes (SOX9, CD44, collagen type II1). Moreover at the entire process of reprogramming and the differentiation of the cells culture the population of differentiated cells was examined using immunofluorescence, and immunohistochemistry (safranin O, collagen type II). We are going to perform a global analysis of gene expression at different stages of hES, and IPS cells differentiation. These analyzes based on RNA microarray technology will be made in collaboration with the Institute of Applied Cancer Center, MD Anderson, University of Texas. The experience gained by the project manager in the TCGA (Tumor Cancer Genome Atlas) Researches enable the validation of the most important genes involved in the molecular mechanisms controlling stem cells differentiation using RT-PCR.
In a further step we are going to study the protocol for differentiation IPS cells toward chondrocytes. Obtained chondrocytes will be used as a transplants for repairing cartilage damage in vivo according to the previously developed methodology. The model of in vitro analysis of regeneration the articular cartilage has been developed. Animal study are performed in collaboration with team of Dr Trzeciak from Department and Clinic of Orthopedics and Traumatology, Poznań University of Medical Sciences. We are going to examine the mechanism of repair of so-called full thickness cartilage damage which penetrates subchondral bone.
The results of the experiments will form the basis for the development of regenerative medicine and may contribute to the development of clinical protocols for future acquisition of chondrocytes from the patient's somatic cells.

W-2376

HUMAN PLURIPOTENT STEM CELLS AS A POTENTIAL SOURCE OF CLINICAL-SCALE NUMBERS OF FUNCTIONAL CHONDROPROGENITORS FOR THE REPAIR OF DAMAGED CARTILAGE

Katsutsugu Umeda, Jiangang Zhao, Brian R. Davis, Naoki Nakayama
Brown Foundation Institute of Molecular Medicine, The University of Texas Health Science Center at Houston, Houston, TX, United States

The human body is unable to repair damaged joint cartilage spontaneously, which eventually leads to osteoarthritis. Current cell-based therapies use mainly mesenchymal stromal cells (MSCs) and autologous chondrocytes, which are only available in low yield, necessitating *ex vivo* expansion. Drawbacks of expansion are the associated reduction in (re)chondrogenic activity and increased potential for fibrocartilage formation. Cartilage develops most actively during embryogenesis from three precursors: paraxial mesoderm, lateral plate mesoderm and cranial neural crest, all of which are potentially better suited to the repair of damaged cartilage than expanded adult cells. Since the early processes of *in vitro* differentiation of pluripotent embryonic stem (ES) cells mimic those of *in vivo* embryogenesis, pluripotent stem (PS) cells are the only promising source for human embryonic chondroprogenitors.
The induction of chondrogenesis from human ES cells has been demonstrated *in vitro*. However, most of the published results are based on the use of progeny generated via “uncontrolled” differentiation of ES cells, which generally display only weak chondrogenic activity. In contrast, we have reported the directed development of paraxial mesodermal progeny from human ES and induced pluripotent stem (iPS) cells in a chemically-defined medium (CDM) in the presence of defined signaling molecules that possess greater *in vitro* hyaline- cartilage forming activity than STRO1^{+}, low-passage, human bone marrow MSCs (Umeda, et al.. Sci Rep. 2012; 2:455-65).

A large portion of craniofacial bone and cartilage develop from osteochondrogenic progeny of the cranial neural crest (i.e. ectomesenchyme). In the current study, we have demonstrated that SOX9-expressing $CD271^{+}PDGFR\alpha^{+}CD73^{+}$ chondrogenic ectomesenchymal cells are selectively generated and expanded from the *SOX10*- and *FOXD3*-expressing $MIXL1^{-}CD271^{hi}PDGFR\alpha^{lo}CD73^{-}$ neural crest-like progeny of human ES cells and iPS cells in CDM supplemented with Nodal/Activin/TGFβ inhibitor and FGF. Such ectomesenchymal cells efficiently formed translucent, hyaline-like cartilage particles when "primed" with TGFβ prior to 3-dimensional pellet culture. When applied to an *in vivo* ectopic transplantation mouse model, these cartilage particles matured into mineralized cartilage, suggesting that the developed chondrocytes may be functionally similar to those in the growth plate. The ectomesenchymal cells were expandable for over 16 passages without loss of chondrogenic potential and maintained a normal karyotype for at least 10 passages. Our findings indicate that large, even clinical scale, quantities of active chondrogenic cells can be readily prepared.

In conclusion, the human PS cell-derived $CD271^{+}PDGFR\alpha^{+}CD73^{+}$ ectomesenchymal cells appear to represent an improved cell source for cell-based repair of damaged cartilage, and potentially, the basis for development of a method of cartilage-mediated bone repair.

DIRECTED DIFFERENTIATION OF HUMAN AND MOUSE EMBRYONIC STEM CELLS TO DEFINED NEOCORTICAL SUBTYPES

Mohammad Z. Ozair[1], Gist Croft[1], Dagmar Ogrocki[2], Joanna E. Krzyspiak[1], Ali H. Brivanlou[1]

[1]Laboratory of Molecular Vertebrate Embryology, The Rockefeller University, New York, NY, United States, [2]Life Sciences and Technology, Beuth Hochschule fuer Technik Berlin, Berlin, Germany

The functional specialization of different regions of the human neocortex is dependent on the specification of projection neurons with distinct areal and laminar identities. The establishment of areal identity results in subdivision of the neocortical areas into functional fields such as sensory, visual, and motor. Laminar specification leads to the establishment of the six layers of the neocortex, a feature specific to mammalian brains. While we have a basic understanding of these processes in rodent development, whether these principles are conserved in human development remains unknown. Human embryonic stem cells (hESCs) provide a window into early human development, and have been used as a system to model early corticogenesis. Starting with Activin/Nodal and BMP inhibition, we have established a system for efficient differentiation of hESCs into all the major cortical laminar fates under defined conditions. Additionally, our results suggest that hESC derived neuroepithelium can form the three major progenitor classes found in vivo: radial glial cells, basal progenitors, and outer radial glia in a cell intrinsic manner in the absence of non-neural cells. Using live imaging and genetic tools, we observe that hESC derived neural progenitor cells (hNPCs) display many properties of radial glial cells observed in human fetal slice cultures. Moreover, hNPCs can be patterned to generate different areal identities within the neocortex using developmentally regulated morphogens. Lastly, we have also established an identical system of cortical differentiation in mouse ESCs which now permits highly efficient generation of upper cortical layers, unlike previous protocols. This platform now allows us to compare the similarities and differences in the intrinsic differentiation potential of mouse and human NPCs at the single cell level. Our experiments will allow us to gain a foothold on the molecular and cellular basis of increased complexity of the human neocortex. The ability to generate functional projection neurons with defined areal and laminar identity is a prerequisite for targeted cell therapies. By understanding the molecular underpinnings of the generation of these identities, ultimately our work will also provide a springboard for future region-specific studies on diseases involving the neocortex such as autism, schizophrenia, and Alzheimer's.

EFFECTS OF 50 HZ MAGNETIC FIELD ON THE PROLIFERATION AND NEURONAL DIFFERENTIATION OF MOUSE EMBRYONIC NEURAL STEM CELLS

Yanwen Zhang

Third Military Medical University, Chongqing, China

Recently, several studies indicated that continuous exposure to extremely low-frequency electromagnetic fields (ELF-EMF) may affect the biologic behavior of neural stem cells (NSCs).
The aim of the present study was to investigate the possible effect of intermittent ELF-EMF exposure on NSCs. Primary cultured embryonic neural stem cells (NSCs) were exposed to a 50 Hz magnetic field (MF) at 0.5 mT, 1 mT and 2 mT for 24 h, 48 h and 72 h respectively, with intermittent cycle of 5 min on/10 min off. Cell proliferation was measureded by CCK-8 assay and Edu incorporation. Cell cycle was analyzed using a flow cytometer. The neuronal differentiation of NSCs was detected by the percentage of Tuj1 positive cells. No significant change of cell proliferation (0.5 mT, 1 mT, 2 mT for 72 h and 2 mT for 24 h, 48 h, 72 h), cell cycle(2 mT for 72 h) and neuronal differentiation(2 mT for 72 h) was observed between 50 Hz-MF-exposured and sham-exposured NSCs. Our results suggest that the present 50 Hz-MF exposure did not cause marked toxicity to NSCs.

UAF1 REGULATES DIFFERENTIATION OF EMBRYONIC STEM CELLS.

Eunmi Park, Jungmin Kim, Kalindi Parmar, David Weinstock, Julie Sahalie, George Q. Daley, Alan D. D'Andrea
Radiation oncology, Dana-Farber Cancer Institute, boston, MA, United States

Fanconi anemia (FA) is an autosomal recessive disease characterized by bone marrow failure, congenital abnormalities, heightened cancer susceptibility and cellular hypersensitivity to DNA cross-linking agents. There are 15 FA proteins, and they co-operate in a common DNA repair pathway to promote cellular resistance to DNA cross-linking agents. Disruption of this FA pathway leads to a DNA repair disorder and to a hematopoietic stem cell defect. A central event in the FA pathway is the monoubiquitination of the FANCD2 protein. Our laboratory has identified a specific ubiquitin specific protease complex, USP1/UAF1, which controls the deubiquitination of FANCD2-Ub. UAF1 (USP1 associated factor-1) binds and stimulates the USP1 enzyme activity. In order to understand the role of USP1 in pathogenesis of FA, we have previously characterized Usp1 mutant mice. Usp1 -/- mice had elevated perinatal lethality, male infertility, cellular crosslinker hypersensitivity, and an FA phenotype. To further investigate the function of USP1/UAF1 complex, we next disrupted murine Uaf1 gene. Unexpectedly, Uaf1-/- mice exhibited early embryonic lethality. We therefore generated Uaf1 -/- mESCs (mouse embryonic stem cells). As expected, Uaf1 -/- mESCs had increased Fancd2 monoubiquitination and were hypersensitive to DNA cross-linking agent. Moreover, Uaf1 -/- mESC colonies were significantly smaller than the wild-type mESC colonies. To investigate a role of Uaf1 in regulating ES cell differentiation, we differentiated wild-type and Uaf1 -/- mESCs in vitro by leukemia inhibitory factor (LIF) withdrawal and determined mRNA expression of differentiation markers. Interestingly, at day 6 and 8 of differentiation, Uaf1 -/- mESCs displayed increased expression of genes regulating the mesoderm lineage, namely, Bmp4, Hoxa1, and Brachyury (T). In addition, at day 2 of differentiation, Uaf1-/- mESCs had increased expression of Fgf5, a primitive ectoderm marker. Since vertebrate mesoderm gives rise to a diverse variety of tissues, including the muscle, vasculature, and blood,, we are currently testing the role of Uaf1 in hematopoietic cell differentiation. Collectively, our results suggest that besides regulating a DNA repair pathway, Uaf1 and perhaps Usp1/Uaf1 complex proteins, also regulate embryonic development and differentiation.

W-2382

THE LOCALIZED FAS ON CELL SURFACE INDUCES THE DIFFERENTIATION OF MOUSE EMBRYONIC STEM CELLS

Kazumi Hirano[1], Chikara Sato[2], Shoko Nishihara[1]
[1]Soka University, Hachioji, Japan, [2]Biomedical Research Institute, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan

Fas signaling is a major signaling of apoptosis. Fas signaling is activated by binding of Fas ligand to Fas or simply by redistribution of Fas into lipid rafts. After clustering of Fas on lipid rafts, Fas is internalized into endosomal compartments in a clathrin-dependent manner and forms receptosome beneath the cell surface. Subsequently Fas-re-

ceptosome activates caspase-8 and caspase-3. Recently, we have reported that Fas, which localized in the intracellular Golgi compartment around the nucleus, was recruited into lipid raft by heparan sulfate 3-O sulfated structure (3-O sulfated HS) on heparan sulfate proteoglycan during differentiation of mouse embryonic stem cells (mESCs). Treatment of brefeldin A, which inhibits the retrograde transport of proteins in endoplasmic reticulum and Golgi compartment, reduced the increased expression of Fas on cell surface in cells overexpressing 3-O sulfated HS, indicating that Fas was carried from Golgi compartment to cell surface. We also found that the activation of Fas signaling via 3-O sulfated HS induced the degradation of Nanog mediated by caspase-3 and differentiated into primitive endoderm and primitive ectoderm. The localization of Fas was further analyzed by atmospheric scanning electron microscopy (ASEM). The ASEM enables us to observe the sample in wet condition, such as cultured cells. The disposable dish with a silicon nitride (SiN) film window in a bottom allows various types of cells to be cultured. The use of this system permits direct observation of subcellular structures and localization of proteins of interest in wet cells at SEM resolution. To examine localization of Fas in detail, we used goat Fab' against mouse IgG doubly conjugated with 1.4 nm Nanogold and fluorescent Alexa Fluor 594 as a secondary antibody. ASEM is able to visualize samples at 8 nm resolution. The ASEM clearly showed that Fas was localized on cell surface and formed Fas-receptosome in differentiated mESCs induced by LIF withdrawal. These findings demonstrate that the localized Fas on cell surface induced the differentiation of mESCs.

NOVEL INTEGRATIVE NUCLEAR FGFR1 SIGNALING (INFS) COMPLEMENTS PLURIPOTENCY AND CELL CYCLE MODULES IN STEM CELL DEVELOPMENT.

Christopher Terranova[1], Shridhar Narla[1], Barbara Birkaya[1], Yu-Wei Lee[1], Ewa K. Stachowiak[1], Michael Buck[2], Abhi Parikh[3], Emmanuel Tzanakakis[1], Michal K. Stachowiak[1]
[A]Pathology and Anatomical Sciences, [B]Biochemistry, [C]Chemical and Biological Engineering, [1]SUNY at Buffalo, Buffalo, NY, United States

Ontogeny requires coordinated regulation of multi-gene programs by a plethora of epigenetic signals to execute the cell transitions between self-renewal, proliferative expansion and differentiation. Systems biology postulates computational modules which integrate environmental information to control entry into the cell cycle and promote perpetual self-renewal by the stem cells. We identified an analogous Feed-Forward-And Gate module that effects postmitotic development and neuronal differentiation by the stem cells *("Stem Cells-From Mechanisms to Technologies",M.K. Stachowiak, E. S. Tzanakakis edts.World Scientific).* In the center of this module resides a novel gene-activating mechanism "Integrative Nuclear Fibroblast Growth Factor Receptor-1 (FGFR1) Signaling" (INFS). In INFS, stimulation of diverse cell surface neurotransmitter, hormonal or growth factor receptors leads to a nuclear accumulation of FGFR1, interaction and activation of limiting CBP and transcription activation. The INFS mechanism mediates cAMP-induced neuronal differentiation of multipotent human neural progenitor cells and in vivo differentiation of brain stem cells. We recently demonstrated that the activation of INFS is a common response of the pluripotent human (h) and mouse (m) ESC to all-trans Retinoic Acid (RA). .Nuclear FGFR1 is both essential for the RA induced mESC neuronal differentiation and sufficient to induce differentiation in the absence of RA stimulation. Nuclear FGFR1 associates with RXR/RAR and Nur proteins, binds to chromatin and activates gene transcription. Blocking INFS by nuclear dominant negative FGFR1(SP-/NLS(TK-) inhibits RA activation of the RARE, NurRE and NBRE enhancers while an active nuclear FGFR1(SP-/NLS) augments the RA transduction. Gene-seq indicates the INFS control of the pluripotency, neurodevelopmental and mesodermal gene programs.This study establishes further the role of the INFS signalling module that drives stem cell development. This work was supported by NYSTEM contracts C026415 and C026714.

INHIBITION OF ROCKS ENHANCE THE FORMATION OF HEMOGENIC MESODERM AND BLOOD FROM MOUSE EMBRYONIC STEM CELLS

Michael J. Chen, Xaio Guan, Sumon M. Datta, Gloria Lee, George Q. Daley, Leonard I. Zon, Thorsten M. Schlaeger
Hematology/Oncology, Boston Children's Hospital, Boston, MA, United States

Faithfully recapitulating the key commitment stages during embryo development can facilitate direct differentiation of target tissues in vitro. In developing embryos, hematopoietic stem and progenitor cells (HSPCs) emerge from hemogenic endothelium, which is derived from Flk1+ mesodermal precursors. Mesoderm and definitive endoderm are derived from posterior and anterior primitive streak, respectively, during gastrulation. To uncover novel regulatory mechanisms and to increase the efficiency of in vitro blood derivation, we conducted a chemical genomics screen of embryonic stem cells (ESCs) carrying Flk1 reporters. We identified the Rho-associated, coiled-coil containing protein kinase (ROCK) inhibitor Y-27632 as a strong inducer for Flk1+ cell generation. Chemical inhibition of ROCK up regulates posterior primitive streak (PS) markers Evx1, HoxB1, and Tbx6, while anterior PS markers Cer1, Gsc, and Foxa2 are down regulated. Inhibition of ROCK also up regulates hematopoietic markers Lmo2, Scl, and Runx1 and increases the number of hematopoietic progenitors. Based on RNAi knockdown experiments, ROCK2 was more potent than ROCK1. Our study thus establishes ROCKs as key modulators for hemogenic mesoderm formation from ESCs.

W-2385

MONITORING CELL PROLIFERATION, DIFFERENTIATION, AND DEATH DURING ENDODERM AND ECTODERM DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS USING MULTIPARAMETER FLOW CYTOMETRY

Nil Emre, Jason G. Vidal, Lissette Wilensky, Erika A. O'Donnell, Christian T. Carson
BD Biosciences, San Diego, CA, United States

During lineage specification in vivo, there are apoptotic and cell proliferation events that accompany the differentiation of cells towards a specific lineage. In this study, we aimed to examine and monitor these events in vitro using multiparameter flow cytometry. Specifically, we examined the differentiation of human embryonic stem cells (hESCs) to definitive endoderm as well as neuronal differentiation from hESC-derived neural stem cells. We designed multicolor flow cytometry assays that enabled us to concomitantly measure and delineate the kinetics of apoptosis, cell proliferation, and differentiation. We mon-

itored active caspase-3, cleaved PARP, and histone H2AX (pS139) to measure apoptosis and DNA damage, and we utilized BrdU and DNA content analysis to monitor proliferation. Additionally, we utilized lineage-specific surface markers and transcription factors to monitor differentiation status to correlate trends in cell fate to their differentiation status. For definitive endoderm, we verified our differentiation through monitoring the down-regulation of the pluripotency marker Nanog and the up-regulation of endodermal markers Sox17, FoxA2, and CD184. For neural differentiation, Sox1, Sox2, and Ki-67 were used to identify neural stem cells, and doublecortin was used to identify neurons. Conditions for cellular fixation and permeabilization were optimized to achieve the highest resolution of all markers of interest. The simultaneous analysis of apoptosis, cell proliferation, and differentiation using multiparameter flow cytometry is an invaluable tool to both optimize differentiation protocols as well as understand cellular processes that contribute to lineage specification.

W-2386

FUNCTIONAL GENOMICS IN HUMAN EMBRYONIC STEM CELLS USING RNAI

Kevin Andrew U. Gonzales[1], Huck Hui Ng[2]
[1]NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, Singapore, Singapore, [2]Genome Institute of Singapore, Singapore, Singapore

Embryonic stem cells (ESCs), characterized by the properties of pluripotency and self-renewal, act as a good in vitro model system for early development, where the first cell lineage decisions are made. We set to perform functional genomic screens on human ESCs under various conditions with multiple readouts to identify important contributors to different aspects of human ESC biology such as self-renewal and differentiation. We started with assessing the effects of microRNA mimics on human ESCs under pluripotency-maintaining conditions to monitor microRNA-induced differentiation. Validation of the hits will determine the robustness of our system, and will enable extension of the technique to other experimental settings. Through this multi-dimensional functional genomics approach, we can create functional circuits that govern ESC processes such as early differentiation away from pluripotency and towards specific lineages.

ASTROCYTE BASED APPROACHES TO SPINAL CORD INJURY THERAPY

Chung-Hsuan Shih, Michelle Cooney, Mark Noble, Christoph Pröschel
Biomedical Genetics, University of Rochester, Rochester, NY, United States

Every year about 300,000 patients in the U.S. suffer traumatic injury of the brain or spinal cord. Due to the limited regenerative capability of adult central nervous system (CNS), these patients are facing the debilitating consequence of their injuries. Taking advantage of the neuroregeneration promoting properties of glial cells, we have developed a cell therapy for spinal cord injury (SCI) using a specific type of astrocyte. Previously we have shown that embryonic glial-restricted precursor (GRP) cells can give rise to two distinct types of astrocyte, GDABMP and GDACNTF, upon BMP or CNTF treatment respectively. Transplantation of either rat or human origin of GDAsBMP, but not GDAsCNTF or GRPs promotes extensive neuronal survival, axonal regeneration, and functional recovery in a rat SCI model. To translate this finding into clinical application, we proceed in a two-pronged strategy: 1) to identify the regeneration promoting factors produced by GDAsBMP for future use to enhance SCI therapies; 2) to provide a more accessible source of GDAsBMP-like astrocytes by directed differentiation from human embryonic stem cells (hESCs). Differential expression analysis between GRPs and GDAs revealed a list of candidate factors that can modulate the microenvironment of injured spinal cords to encourage regeneration. Among these candidates, we identified the novel soluble factor, SF3, selectively expressed by GDAsBMP and essential for GDABMP induced neurite extension. Perturbing SF3 expression by shRNA compromised GDABMP mediated axonal regeneration after transection injury in spinal cord. Recombinant SF3 overcame adverse effect of inhibitory substrates enriched at the site of CNS lesion and promotes neurite extension in culture neurons. Lastly we have derived human astrocytes from hESCs through an intermediate neural progenitor stage. These hESC-derived astrocytes recapitulate characteristics

of GDAsBMP with respect to neuronal survival and axonal outgrowth promoting effects. These results provide clinical applicable strategies for future SCI therapy.

GPCR SCREENING IDENTIFIES THE THROMBIN RECEPTOR PAR1 AS A NOVEL REGULATOR OF MOUSE EMBRYONIC STEM CELL (MESC) DIFFERENTIATION INTO VASCULAR ENDOTHELIUM

Min Zhang[1], Yanmin Zhang[1], Fei Li[1], Kraig Theriault[1], Haixia Gong[1], Antonia Sassmann[2], Stefan Offermanns[2], Jalees Rehman[1], Asrar B. Malik[1]

[1]Univ of Illinois at Chicago, Chicago, IL, United States, [2]Max-Planck-Institute for Heart and Lung Research, Germany, Bad Nauheim, Germany

Little is known about mechanisms that regulate differentiation of embryonic stem cells (ESCs) to endothelial cells (ECs). Here we investigated the role of G protein signaling based on our initial evidence that suppressing the Gαi signaling pathway augments vascular differentiation. By performing screeming for ~500 G protein coupled receptors (GPCRs), we identified a thrombin receptor, protease-activated receptor 1(Par1) as a candidate. Par1 is significantly up-regulated during endothelial differentiation of mouse ESCs (mESCs). Using FACS analysis, we observed that treatment of mESCs during differentiation to ECs with siPar1 or the Par1 selective antagonist SCH79797 doubled the generation of cells co-expressing the EC markers Flk1 and VE-cadherin. Quantitative PCR showed greater increases in Flk1 and VE-cadherin mRNA expression of siPar1 or SCH79797 treated cells than controls. Conversely, a Par1 agonist peptide and the physiologic Par1 agonist thrombin both significantly inhibited the differentiation of mESCs to ECs. Further dissection of the signaling pathways demonstrated that Par1 acts via the Gαi/PI3K pathway to inhibit endothelial differentiation of mESCs. We are currently generating mouse iPSCs from Par1-deficient mice to assess their capacity for endothelial differentiation. These results represent the first comprehensive screening of GPCRs that are involved in vascular differentiation of pluripotent stem cells and have identified a specific, druggable GPCR that regulates vascular differentiation. This also has important implications of vascular regeneration and repair following acute lung injury, because pluripotent stem cell derived vascular cells can augment vascular repair. Blockade of Par1 not only increases the yield of therapeutic ESC derived endothelial cells (ESC-ECs), but may also help ensure maturation and survival of transplanted ESC-ECs in situ.

USING MOUSE EMBRYONIC STEM CELLS TO IDENTIFY MORPHOGENS AND SIGNALING MOLECULES INVOLVED IN DEVELOPMENTAL AND FUNCTIONAL ASPECTS OF GRANULAR HIPPOCAMPAL NEURONS

Maryam Hatami[1], Steffen Albrecht[1], Sabine Conrad[2], Thomas Skutella[1]

[1]Anatomy and cell biology, Heidelberg, Germany, [2]Biology and medicine university, Tübingen, Germany

Objectives: The dentate gyrus plays a crucial role in hippocampal function as the main primary afferent excitatory pathway into the hippocampus. The development of the dentate gyrus is characterized by various phases establishing a heterogeneous stem cell pool and morphogens and molecular signaling cascade that are required for distinct neurogenic steps. Since little is known about the molecular control of dentate granule cells development, research efforts have been concentrated in deducing the cascade of events that lead to the differentiation of the neuroepithelial cells into granule neurons.
Results: To characterize the role of different morphogens in development of the granule cells we have investigated the effect of morphogens such as Wnt3a, BMP-4, Dkk3a, and FGF8b.Wnt3a and FGF8b have more effect to lead differentiation into granule neurons. Some other morphology although observed such as oligodendrocytes.
Conclusions: Our results indicate that sequential treatment with morphogens may play a key role to lead differentiation of neural progenitor cells into granule neurons.

A HUMAN INDUCED PLURIPOTENT STEM CELL MODEL OF LIGASE IV DEFICIENCY REVEALS AN IMPORTANT ROLE FOR NHEJ-MEDIATED-DSB REPAIR DURING HUMAN EMBRYONIC HAEMATOPOIESIS

Majlinda Lako[1], Katarzyna Tilgner[1], Irina Neganova[1], Sun Yung[1], Chatchawan Singhapol[2], Gabriele Saretzki[2], Jerome Evans[1], Vera Gorbunova[4], Andrew Gennery[3], Stefan Przyborski[5], Miodrag Stojkovic[6], Lyle Armstrong[1], Penny Jeggo[7]

[A]Institute of Genetic Medicine, [B]Institute for Ageing and Health, [C]Institute of Cellular Medicine, [1]Newcastle University, Newcastle, United Kingdom, [2]Department of Biology, University of Rochester, Rochester, NY, United States, [3]6.School of Biological and Biomedical Sciences, Durham University, Newcastle, United Kingdom, [4]Human Genetics Department, University of Kragujevac, Newcastle, United Kingdom, [5]Genome Damage and Stability Centre, University of Sussex,, Brighton, United Kingdom

DNA double strand breaks (DSBs) are the most common form of DNA damage and are repaired by non-homologous-end-joining (NHEJ) or homologous recombination (HR). Several protein components function in NHEJ, and of these, DNA Ligase IV is essential for performing the final 'end-joining' step. Mutations in *DNA Ligase IV* result in LIG4 Syndrome which is characterised by growth defects, microcephaly, reduced number of blood cells, increased predisposition to leukaemia and variable degrees of immunodeficiency. We report the creation of a human induced pluripotent stem cell (iPSC) model of LIG4 deficiency which accurately replicates the DSB repair phenotype of LIG4 patients. Our results demonstrate that impairment of NHEJ-mediated-DSB repair in human iPSC results in accumulation of DSBs, enhanced apoptosis and increased genomic instability, thus providing new insights into likely mechanisms used by pluripotent stem cells to maintain their genomic integrity. While haematopoietic specification of LIG4-iPSC is not affected *per se*, the emerging haematopoietic progenitors show a high accumulation of DSBs and enhanced apoptosis, resulting in reduced numbers of mature haematopoietic cells. Together our findings provide new insights onto the role of NHEJ-mediated-DSB repair in proliferation and differentiation of progenitor cells, which likely underlies the developmental abnormalities observed in many DNA damage disorders. In addition, our findings are important for understanding how genomic instability arises in stem cells and for defining appropriate culture conditions that restrict DNA damage and result in *ex vivo* expansion of stem cells with intact genomes.

DIFFERENTIATION OF HUMAN ES CELLS TOWARDS OCULAR LENS: LENS CELL LINEAGE FORMATION, SUPPRESSION OF ALTERNATE CELL FATES, AND LENS TISSUE ENGINEERING

Rebecca S. McGreal[1], Yang Jing[1], Eric E. Bouhassira[2], Ales Cvekl[1]

[A]Department of Opthalmology and Visual Sciences, [B]Department of Medicine, Hematology, [1]Albert Einstein College of Medicine, Bronx, NY, United States

Abnormal embryonic lens development can result from a variety of genetic mutations affecting DNA-binding transcription factors, lens structural proteins, such as crystallins, and other important proteins. Such mutations may lead to congenital cataracts, which are often associated with other eye malformations. Age-related cataract is responsible for almost half of blindness world-wide. The lack of appropriate animal models as well as various limit-

ations of human primary lens cultures currently restrict the study of human cataract, therefore, the establishment of an efficient in vitro system to direct human embryonic stem (hES) cell differentiation towards lens progenitors and mature lens cells will advance studies of lens development and mechanisms of cataractogenesis.
We have previously developed a 3-stage system to differentiate hES cells into large quantities of lens-progenitor like cells and 3-dimensional lentoid bodies over 35 days of culture. Here, we optimized these conditions using various concentrations of growth factors and drugs. We found that a lower concentration of FGF2 (20 ng/mL reduced from 100 ng/mL) used to generate lentoid bodies was optimal for expression of key markers of differentiated lens. We also found that a range of FGF2 concentrations can influence hES cell fate decisions between the neuroectoderm, ectoderm/epidermis, neural crest (NC) and the pre-placodal region (PPR) as indicated by the expression levels of specific markers for the different cell types. Lentoid body cultures can now be extended to at least 70-100 days. Various drugs were tested to facilitate lentoid growth, including rho-ROCK kinase inhibitors (fasudil), drugs known to induce cellular differentiation (5-azacytidine and decitabine), as well as drugs known to act on autophagy pathways (SP600125 and etoposide). These long-term cultures can be divided into three different stages. “Early lentoids” were developed between day 18 and day 28 in the presence of FGF2 (20 ng/mL) and Fasudil (50 µM). “Intermediate lentoids” are formed between day 29 and day 35 in the presence of FGF2 (20 ng/mL), Fasudil (50 µM), 5-azacytidine (10 µM), and Decitabine (10 µM). “Mature lentoids” with improved differentiation and morphology were formed between day 35 and 70 in the presence of FGF2 (20 ng/mL) and either SP600125 (25 µM) or etoposide (20 µM).
These studies have identified improved differentiation procedures to generate lens cells and conduct long-term cultures to generate transparent 3-dimensional lentoid bodies that refract light from hES cells, an important step towards understanding both human embryonic lens development as well as human cataract.

W-2394

LHX2 REGULATES THE NEURAL DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS VIA TRANSCRIPTIONAL MODULATION OF PAX6 AND CER1

Hung-Chih Kuo[1], Pei-Shan Hou[1], Hong-Nermg Ho[2], Chung-Liang Chien[2]
[1]Academia Sinica, Taipei, Taiwan, [2]National Taiwan University, Taipei, Taiwan

The LIM homeobox 2 transcription factor Lhx2 is known to control crucial aspects of neural development in various species. However, its function in human neural development is still elusive. Here, we demonstrate that LHX2 plays a critical role in human neural differentiation, using human embryonic stem cells (hESCs) as a model. In hESC-derived neural progenitors (hESC-NPs), LHX2 was found to be expressed prior to PAX6, and co-expressed with early neural markers. Conditional ectopic expression of LHX2 promoted neural differentiation, whereas disruption of LHX2 expression in hESCs significantly impaired neural differentiation. Furthermore, we demonstrated that LHX2 regulates neural differentiation at two levels: first, it promotes expression of PAX6 by binding to its active enhancers, and second, it attenuates BMP and WNT signaling by promoting expression of the BMP and WNT antagonist Cerberus 1 gene (CER1), to inhibit non-neural differentiation. These finding indicate that LHX2 regulates the transcription of downstream intrinsic and extrinsic molecules that are essential for early neural differentiation in human.

DOMINANT EFFECT OF MOUSE MUSCULAR DYSTROPHY EMBRYONIC STEM CELLS IN WILD TYPE MICE

James Patrick Gonzalez[1], Joel Schneider[1], Jessica Button[1], Corey Chang[1], Sergii Kyrychenko[1], Victoria Kyrychenko[1], Jonathan Doering[2], Mantu Bhaumik[3], Robert Grange[2], Natalia Shirokova[1], Diego Fraidenraich[1]
[1]UMDNJ, Newark, NJ, United States, [2]Virginia Tech, Blacksburg, VA, United States, [3]UMDNJ, New Brunswick, NJ, United States

We previously created chimeric mice by injecting WT mouse embryonic stem (ES) cells and induced pluripotent stem cells into mdx (dystrophin-negative) blastocysts, which are predisposed to develop symptoms of Duchenne

muscular dystrophy (DMD). We determined that a low percentage of ES cells was sufficient to supply dystrophin to the heart and skeletal muscles, producing a significant amelioration of disease (Stillwell et al. and Beck et al., PLoS one 2009 and 2011).
Recently, we generated mosaic mice by injecting mdx ES cells into WT blastocysts (termed 'reverse' chimeras). With low levels of ES cell incorporation (10-30%), the mdx/WT chimeric heart acquired dystrophic features, specifically in terms of intracellular calcium responses to mechanical stress, well before normal onset would occur in the mdx heart. While the ES-derived mdx cardiac myocytes behaved like typical mdx cardiac myocytes, surprisingly the embryo-derived WT cardiac myocytes also behaved as mdx cardiac myocytes. In addition to the effects on the heart, we observed that at a higher degree of chimerism (30-50%), some skeletal muscles like the pectoralis and diaphragm, but not the quadriceps or soleus, showed histological features of muscular dystrophy. Affected muscles displayed both a non-uniform expression of dystrophin and compromised utrophin upregulation in fibers with negligible dystrophin. Preliminary functional studies revealed that the EDL muscles, but not the soleus muscles, are sensitive to mdx ES cell chimerism, as the EDL twitch and tetanic forces, and shortening velocities were attenuated. At similar levels of chimerism, mature adipocytes showed an upregulation of muscle and cardiac markers, and evaluation of related changes in secreted hypertrophic factors such as Wnt5a and follistatin-like proteins is underway. Together, our findings suggest that the ES-derived mdx compartment dictates the overall phenotype in the heart, certain skeletal muscles, and the fat of these 'reverse' chimeras.
As mosaicism is a common feature in DMD (dystrophin+/-) carriers and in Becker muscular dystrophy, this unsuspected dominant, muscle specific function of the mdx ES-derived cells merits further studies.

PANCREATIC-SPECIFIC EMBRYONIC MESENCHYME ENHANCES HUMAN EMBRYONIC STEM CELL DIFFERENTIATION TOWARDS PANCREATIC LINEAGES

Michael A. Bukys, Carolina Parada, Jan Jensen
Stem Cell Biology & Regenerative Medicine, Cleveland Clinic Lerner Research Institute, Cleveland, OH, United States

Human embryonic stem (hES) cells are characterized by an unlimited growth potential coupled with the capacity to form all cell-types of the adult organism. These abilities make hES cells a promising renewable source of insulin secreting cells needed for diabetes therapy. Here we test the ability of pancreatic specific mesenchyme to drive the differentiation of hES cultures towards pancreatic fates. Pancreatic tissue from E13.5 timed litters were dissected out and pooled followed by a combination of mechanical and enzymatic digestions to generate seed cultures. Two subsequent trypsin mediated passages over the course of the next four days removed evidence of epithelium components from these primary cultures as determined through RT-PCR, genomics, and cytological approaches. Initial hES differentiation experiments established that conditioned medium derived from low-passage, pancreas-specific, mesenchymal cultures (hence forward referred to as Pan-CM) had a greatly diminished capacity to sustain pluripotency of H1 hESCs as evident through decreased Oct3/4, Nanog and Sox2 expression. In addition, pluripotent cultures sustained in the presence of Pan-CM displayed an increasingly endodermal phenotype, as evident through widespread FoxA2 expression. When compared to similar mesenchymal cultures generated from lung, intestine, stomach and liver, a selective inductive ability for pancreatic fate was observed. Following two weeks of continued exposure of Pan-CM to pluripotent cultures resulted in several discrete cyst-like outgrowths and a corresponding transcript analysis demonstrated a selective up-regulation of markers associated with pancreatic progenitor cells (Pdx1, Nkx6.1, Hnf6), ductal cells (Krt 19, Ift88) and endocrine cells (Glucagon, Somatostatin). IHC analysis of the hES-derived cyst demonstrated uniform Pdx1/Hnf6 expression within DBA+ regions with limited endocrine cell development, suggesting that the Pan-CM mediated differentiation event directed hES cultures towards a pancreatic progenitor state while limiting terminal differentiation. To help determine the critical components of the Pan-CM needed to induce this pancreatic phenotype within a forward differentiating hES culture a combined analysis of the corresponding transcriptome (microarray approach) and the secretome (LC-MS approach) of the pancreas-specific mesenchymal cultures was undertaken. Several signaling molecules were identified which were uniquely expressed within the pancreas-specific mesenchymal when compared to similar mesenchymal cultures derived from lung, in-

testine, stomach, and liver. The application of such molecules, in context of a completely defined medium partially recapitulated the Pan-CM induced differentiation event.
This current study demonstrates that primary, embryonic, pancreatic-specific mesenchymal cells are capable of directly informing organ identity of pluripotent cells. The identification of a unique combination of secreted factors expressed by such cells provides a practical approach in the further exploration of optimizing induction of pancreatic fate from pluripotency.

HUMAN PLURIPOTENT STEM CELL DERIVED MESENCHYMOANGIOBLASTS HAVE PERICYTE AND SMOOTH MUSCLE CELL POTENTIAL

Akhilesh Kumar, Saritha S. D'Souza, Igor I. Slukvin
National Primate Research Center, University of Wisconsin, Madison, WI, United States

Human pluripotent stem cells (hPSCs), either embryonic or induced, provide access to the earliest stages of human development and offer a plentiful platform for the derivation of large number of vasculogenic cells for cellular therapy and tissue engineering. We recently identified a common precursor of mesenchymal and endothelial cells, mesenchymoangioblast (MAB), as the source of mesoderm-derived MSCs in hPSC differentiation cultures. MABs can be specifically identified using serum-free FGF2-containing semisolid clonogenic medium. In these conditions, MABs form mesenchymal colonies (MS), which give rise to MSCs with osteo-, chondro-, and adipogenic potential. Here, we show that the MS colonies are capable of differentiating into pericytes and smooth muscles cells under the influence of PDGF-BB and sphingosylphosphorylcholine (SPC), respectively. Smooth muscle cells isolated and propagated from MS colonies were found to highly express specific smooth muscle cell (SMC) markers including alpha-smooth muscle actin, calponin, SM22, Myocardin (MYOCD) and smooth muscle myosin heavy chain (MYH11) and displayed strong contractile response to a carbachol and KCL vasoconstrictors. The pericytes, on the other hand, were negative for most of the smooth muscle markers, expressed high level of RGS5, CD146, CD44, CD90, CD13, and NG2 markers, and showed low levels of contractile activity as studied by time-lapse imaging. In vitro tubulogenesis assays revealed that MS colony-derived SMCs interacted with HUVECs to form short lived longer and thicker cord-like structures in vitro. The pericytes, however, are recruited to bind to capillary-like networks on the matrigel and stabilized this network. Overall, our studies demonstrated than MABs have broader differentiation potential than previously thought, and are capable of generating smooth muscle cells and pericytes in addition to MSCs and endothelial cells. Thus, MABs have a potential to provide all essential components of the vasculature and perhaps a scalable source of the entire spectrum of cells required for therapeutic vascular tissue engineering.

DEFINED EXTRACELLULAR MATRIX COMPONENTS ARE NECESSARY FOR DEFINITIVE ENDODERM INDUCTION

Hermes Taylor-Weiner[1], Jean E. Schwarzbauer[2], Adam J. Engler[1]
[1]Bioengineering, Univ of California San Diego, La Jolla, CA, United States, [2]Princeton University, Princeton, NJ, United States

Differentiation methods often rely exclusively on growth factors to direct mouse embryonic stem cell (ESC) fate, but the niche also contains fibrillar extracellular matrix (ECM) proteins, including fibronectin (FN) and laminins (LN), which could also direct cell fate. Soluble differentiation factors are known to increase ECM expression, yet ECM's ability to direct ESC fate is not well understood. To address the extent to which these proteins when assembled into a matrix regulate differentiation, we examined mouse ESC embryoid bodies and found that their ability to maintain pluripotency marker expression was impaired by soluble serum FN. Embryoid bodies also showed a spatiotemporal correlation between expression of FN and GATA4, a marker of definitive endoderm (DE), and an inverse correlation between FN and Nanog, a pluripotency marker. Maintenance of mouse ESC pluripotency prevented fibrillar matrix production, but induction media created lineage-specific ECM containing varying amounts of FN and LN. Mouse ESC-derived matrix was unlike conventional fibroblast-derived matrix, which did not contain LN. Naïve mouse ESCs

plated onto mouse ESC- and fibroblast-derived matrix exhibited composition-specific differentiation with low ECM producing lineages showing improved differentiation on a mouse ESC-derived ECM compared to a fibroblast-derived or gelatin matrix. Fibroblast-derived matrix, when grown with exogenously added LN, is more similar in composition to mouse ESC-derived matrix and lacks residual growth factors that mouse ESC matrix may contain. Naïve mouse ESCs in DE induction medium exhibited dose-dependent DE differentiation as a function of the amount of exogenous LN in the matrix. These data imply that fibrillar FN is necessary for loss of pluripotency and that LN within a FN matrix improves DE differentiation.

SEQUENTIALLY TARGETING DEVELOPMENTALLY EXPRESSED RECEPTORS OF THE FETAL HUMAN LATERAL GANGLIONIC EMINENCE PERMITS THE EFFICIENT INSTRUCTION OF HUMAN MEDIUM SPINY NEURONS FROM HUMAN ESCS

Su Wang, Xiaojie Li, Devin Chandler-Militello, Steven A. Goldman
CTN and Neurology, University of Rochester Medical Center, Rochester, NY, United States

Medium spiny neurons (MSNs) of the striatum are a principal cell type lost in Huntington disease (HD), a disorder characterized by a toxic gain-of-function CAG repeat expansion in the huntingtin gene. Isolated preparations of human MSNs are needed for pharmacotherapeutic screening as well as for potential cellular therapeutics. To develop an efficient protocol for generating MSNs from pluripotential stem cells, we first isolated human MSNs from fetal forebrain tissue, using DLX5 enhancer-driven EGFP-directed fluorescence activated cell sorting to isolate striatal progenitor cells from their source in the second trimester human fetal lateral ganglionic eminence. We cultured the resultant progenitor isolates, and determined that virtually all Dlx5:EGFP+ neuronal daughters differentiated as DARPP32+ MSNs. We then used Affymetrix microarrays to define the expression profiles of these human MSNs, as well as of their parental Dlx5:EGFP+ LGE progenitors; by comparing these profiles to those of SOX2+ human fetal neural progenitor cells, we established a set of genes differentially expressed during human MSN differentiation. This analysis revealed a set of receptors selectively expressed by developing MSNs, and allowed us to predict the ligands to which MSNs were differentially exposed during ontogenesis. Among these sequentially expressed MSN-lineage receptors and their predicted ligands or modulators thereof were NTRK2/BDNF, ACVR/Activin, LPR5:FZD/DKK1, PLXNA2:3/SEMA3, THRA:B/T3, INSR/insulin, and IGF1R/IGF1. Using this information, we designed a high efficiency protocol for generating MSNs from both normal (H9/WA09 and GENEA19) and huntingtin mutant (GENEA 20) human embryonic stem cells. We found that induction of the MSN phenotype was significantly potentiated by the sequential and combinatorial application of these agents, relative to extant protocols for MSN production, such that >80% of all cells in the resultant cultures, and 82 ± 2.5% of neurons, expressed a HuD+/GAD67+/DARPP32+ antigenic phenotype characteristic of MSNs. Thus, human medium spiny neurons may now be efficiently generated from human ESCs, including both normal and HD mutant hESC lines; these ells should permit a hitherto unachievable level of molecular analysis of both normative MSN biology, and its disruption in HD.

FUNCTIONAL ROLE OF MST1/MST2 IN EMBRYONIC STEM CELL DIFFERENTIATION

LI PENG
Chemical Pathology, The Chinese University of Hong Kong, Hong Kong, China

Abstract: Mammalian sterile 20-like kinases 1 and 2 (Mst1/Mst2) are key components of Hippo pathway which is implicated in cell proliferation, apoptosis and organ size control. Recent research suggests that Mst1/Mst2 contribute to restrain tissue specific stem cell compartment in organ. To understand the role of Mst1/Mst2 in stem cells and harness stem cells for better therapeutic application, we derived M*st1/Mst2* knockout embryonic stem cells (*Mst-/-* ES cells) to systematically esplore their lineage differentiation potential. We found that *Mst-/- ES cells* express low level of phosphorylated Yap compared to wild type ES cells, suggesting Hippo pathway is functional in ES cells. *Mst-/-* ES cells cells proliferate faster than wild type cells and show differentiation resistance after LIF with-

drawal. Interestingly, although *Mst-/-* ES cells form embryoid body (EBs) and differentiate into tissues of three germ layers, they do not form teratoma. Genome-wide RNA-seq and microarray analysis revealed that canonical Wnt signaling is significantly repressed in *Mst-/-* EBs. Besides, although *Mst-/-* ES cells can differentiate into mesoderm cells, they fail to differentiate into cardiac progenitor cells. These results would enable us to explore pharmacological alteration of Mst function to regulate cardiac progenitor cell development and prevent teratoma formation during ES cell application in future.
Keywords: Hippo pathway, *Mst1/Mst2* knockout ES cell, Pluripotency, Lineage differentiation, Wnt pathway.

REGULATION OF EMBRYONIC STEM CELL PLURIPOTENCY BY GLYCOGEN SYNTHASE KINASE-3

Mansi Shinde, Peter S. Klein
Perelman School of Medicine at UPENN, Philadelphia, PA, United States

Embryonic Stem cells (ESCs) are characterized by their ability to self-renew indefinitely, while retaining the capacity to differentiate into all lineages. The ability to control cell fate decisions possesses great therapeutic potential for regenerative medicine, and provides a valuable research tool. Glycogen synthase kinase-3 (GSK-3) has been implicated as a key regulator of pluripotency in ESCs. Although short-term GSK-3 inhibition in mouse ESCs enhances self-renewal through Wnt activation, cells cultured with GSK-3 inhibitors alone eventually succumb to differentiation. Although GSK-3 is best-known for its role in Wnt/β-catenin signaling, it functions in several other growth factor signaling pathways that have not been studied in ESCs. We hypothesize that GSK-3 inhibition promotes differentiation through activation of mechanistic Target of Rapamycin (mTOR). Our lab has previously shown that, in mouse hematopoietic stem cells (HSCs), GSK-3 regulates both self-renewal, through Wnt/β-catenin signaling, and lineage commitment, through mTOR. mTOR is a key nutrient sensing pathway that integrates extracellular and intracellular signals to regulate many cell processes, such as protein translation and autophagy. We hypothesize that mTOR promotes lineage commitment, as biosynthetic capacity and nutritional status may play a role in pluripotency. The objective of this study is to assess whether GSK-3 regulates pluripotency through Wnt/β-catenin signaling, and inhibits lineage commitment through mTOR in ESCs. Specifically, we are testing if GSK-3 inhibition activates mTOR in ESCs and whether this increase in mTOR activity contributes to differentiation. In *Gsk-3α/Gsk-3β* double knockout (*Gsk-3* DKO) ESCs and in ESCs treated with GSK-3 inhibitor, CHIR9901, we observe markedly increased mTOR activity compared to E14 wild-type ESCs, consistent with known GSK-3 suppression of mTOR in other cell types. Furthermore, when wild-type ESCs are removed from nutrient rich medium and induced to differentiate, mTOR activity initially decreases, but is restored as differentiation progresses. In contrast, mTOR and Wnt/β-catenin activity remain high in *Gsk-3* DKO ESCs, which maintain expression of the pluripotency markers for up to 14 days after induction of differentiation. Our studies in mouse ESCs support a role for a GSK-3/mTOR signaling axis in ESC differentiation.

NEUROGENESIS OF HUMAN CORTICOSPINAL MOTOR NEURONS

Anders Smith[1], Sandra Klein[1], Arturo Zapata[1], James Weimann[2], Binhai Zheng[1]
[1]Neurosciences, UCSD, San Diego, CA, United States, [2]Neurosurgery, Stanford University, Stanford, CA, United States

Corticospinal Motor Neurons (CSMNs) send axonal projections from the sensorimotor cortex to the spinal cord and are vital for skilled voluntary movement in humans. They are damaged or undergo degeneration in spinal cord injury and amyotrophic lateral sclerosis (ALS) respectively, and thus are a clinically important population of cortical projection neurons. Due to the poor regenerative capabilities of the human central nervous system (CNS), treatments for afflicted patients are limited and nervous system damage is often permanent, resulting in chronic paralysis and other difficulties. Despite the extensive work performed in mouse models, CSMN development in humans is poorly understood. The pluripotent nature of human embryonic stem cells (hESCs) renders them an ideal vehicle to address this major gap in our knowledge base.

Developmental studies in mice have identified Fezf2 as an important marker and fate regulator of the subcerebral projection neurons (including CSMNs). Our lab has previously generated a Fezf2:EYFP hESC reporter line via homologous recombination, placing EYFP (enhanced yellow fluorescent protein) under the control of the endogenous human Fezf2 promoter. Using a differentiation protocol based on dual SMAD inhibition, we have been able to differentiate these genetically labeled hESCs toward a CNS phenotype, and have been successful in generating a relatively high percentage of Fezf2 positive neural precursors and neurons. These were initially evaluated by immunostaining at different time points throughout the differentiation process. Fezf2 positive and negative cells were then further assessed by FACS, qRT-PCR, and time-lapse imaging. Finally, to test the potential of these cells in vivo, Fezf2 expressing cells were transplanted into the cortices of neonatal mice. Through these methods, we have begun to elucidate some of the first aspects of the molecular identity and fate choice for human CSMNs.

Totipotent/Early Embryo Cells

ESTABLISHMENT OF EFFICIENT CONDITIONS FOR SINGLE BLASTOMERE AND WHOLE EMBRYO DEVELOPMENT USING CO-CULTURES

Jasmin Jasmin, Martha de Oliveira Guerra, Vera Maria Peters
Biology Center of Reproduction, Federal University of Juiz de Fora, Juiz de Fora, Brazil

Embryonic stem cells (ESC) are one of the most promising stem cell sources for cell therapy and regenerative medicine. Recently, ESC lines were established from single blastomeres; this method could be used to reduce ethical concerns over harm to embryos but the derivation success rate is low. To derive human or mouse ESC usually a feeder layer from animal source [mouse embryonic fibroblast (MEF)] has been used. However, to the best of our knowledge mesenchymal stem cells (MSC), which secrete several growth factors, and can be easily isolated from human or mouse tissue, have not been tested in ESC derivation. In addition, despite the advances in assisted reproduction techniques, failures in in vitro embryo development continue to occur and approaches such as co-cultivation of whole embryos with MEF or MSC has not been explored. In the present study we have used co-culture of MSC or MEF to cultivate single blastomeres and whole embryos of mice. MSC and MEF were isolated and cultured in DMEM-F12 with 10% fetal bovine serum until reached the third passage. All the embryos were obtained ~42 hours (2nd day) after mating, and the single blastomere or whole embryos were randomly split in the follow groups: CTRL - cultivated in control culture medium; MSC - co-cultivated with MSC; MSCinat - co-cultivated with MSC inactivated for proliferation; and MEFinat - co-cultivated with MEF inactivated for proliferation. The inactivation process was performed due to the high proliferation rate of these cells using mitomycin C. The development of single blastomere or embryo cultures was evaluated daily for 5 days (7th day after mating). We observed at 2 days after mating (day of embryo acquisition) the following stages of development: 87.0% at 2-cell, 6.5% at 3-cell, 3.7% at 4-cell and 2.8% at 5-8-cell. Single blastomeres co-cultivated with MSC, MSCinat or MEFinat formed ESC-like colonies after the 4th day of culture, which was not observed in CTRL condition. In addition, we noted with interest that the blastomeres co-cultivated with MSC or MSCinat had a greater development at all time points and formed a higher number of ESC-like colonies than when co-cultivated with MEFinat (57.1, 42.9 and 28.6% for MSC, MSCinat and MEFinat respectively) on the 5th day of culture. For whole embryo cultures we observed that embryos co-cultivated in MSC, MSCinat or MEFinat groups showed a greater development than in CTRL group after the 3rd day of culture. On the 5th day culture the rate of hatched blastocysts in MSC, MSCinat and MEFinat groups were 23.3, 33.7 and 58.2% higher, respectively, than in CTRL group. In summary, our preliminary data show that MSC seems to be a better feeder layer to obtain ESC-like colonies from single blastomere cultures and both MSC and MEF are able to greatly improve the early embryo development in vitro. Supported by FAPEMIG (BPD-00021-12 and REDE26/11).

W-2412

ATYPICAL PKC, REGULATED BY RHO GTPASES AND MEK/ERK, PHOSPHORYLATES EZRIN DURING EIGHT-CELL EMBRYO COMPACTION

Hongjie Liu[1], Zhaoting Wu[1], Xianle Shi[1], Wenzhi Li[2], Lin Liu[1], Jie Na[2], Hong Cheng[3], **Lingyi Chen**[1]
[1]Nankai Univ, Tianjin, China, [2]Tsinghua Univ, Beijing, China, [3]Institute of Biochemistry and Cell Biology, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China

Phosphorylation of Ezrin T567 plays an important role in eight-cell embryo compaction. Yet, it is not clear how Ezrin phosphorylation is regulated during embryo compaction. Here, we demonstrated that inhibition of Mek/Erk or protein kinase C (PKC) signaling reduced the phosphorylation level of Ezrin T567 in eight-cell compacted embryos. Interestingly, the Rho GTPase inhibitor C3-transferase caused basolateral enrichment of atypical PKC (aPKC), as well as basolateral shift of phosphorylated Ezrin, suggesting aPKC may be a key regulator of Ezrin phosphorylation. Moreover, inhibition of PKC, but not Mek/Erk or Rho GTPases, affected the maintenance of Ezrin phosphorylation in compacted embryos. We further identified that aPKC is indeed required for Ezrin phosphorylation in eight-cell embryos. Taken together, Rho GTPases facilitate the apical distribution of aPKC and Ezrin. Subsequently, aPKC and Mek/Erk work together to promote Ezrin phosphorylation at the apical region, which in turn mediates the apical enrichment of filamentous actin, stabilizing the polarized apical region and allowing embryo compaction. Our data also suggested that aPKC might be the Ezrin kinase during eight-cell embryo compaction.

UNDERSTANDING THE CELL CYCLE IN PRIMORDIAL GERM CELL DEMETHYLATION

Joseph D. Hargan Calvopina, John Vincent, Kevin Nee, Amander Clark
MCDB, UCLA, Los Angeles, CA, United States

The germ line epigenetic ground state is established in germ line progenitors called primordial germ cells (PGCs). This epigenetic landscape is necessary for the production of gametes, and to prevent the inheritance of epialleles to future generations. One major characteristic of the germ line epigenetic ground state is genome-wide depletion of cytosine methylation from the genome. We, and others have shown that depletion of cytosine methylation in PGCs occurs in two phases, the first phase involves a global depletion of cytosine methylation that removes methylated cytosines genome wide. In humans this occurs before 6 weeks, and in mice before e9.5. This is followed by a second phase of demethylation, which occurs in a temporal and locus-specific manner. The second phase is regulated in part by the Ten eleven translocation (Tet) proteins Tet1 and Tet2 and conversion of 5-methylcontisine (5mC) to 5-hydroxymethylcytosine (5hmC) at specific loci. The major working model for Tet-dependent DNA demethylation involves replication-coupled loss of methylated cytosines from the genome. However an alternate model would predict active removal of 5hmC at specific loci independent of cell division. In order to address this directly, we have established a new organ culture model involving the growth of dissected aorta/gonad/mesonephros (AGM) tissues isolated from the mouse embryo at e10.5. During three days of organ culture, we show that PGCs divide on average three times. We also show that in the background of global hypomethylation established in phase 1, PGCs isolated from the organ culture undergo locus-specific DNA demethylation, and this occurs within three days. Using this model we have targeted the PGC cell cycle using chemical inhibitors, and are currently evaluating the effects of cell cycle inhibition on locus-specific DNA demethylation. Results from this work have important implications for understanding the control of DNA methylation in the germ line as well as during embryo development and nuclear reprogramming.

EVIDENCE OF PRIMORDIAL GERM CELL MARKERS IN ADULT LAGOSTOMUS MAXIMUS OVARY - AN ENDEMIC MAMMAL OF SOUTH AMERICA

Nicolas A. Fraunhoffer, Analia Meilerman Abuelafia, Pablo IF Inserra, Noelia P. Leopardo, Alfredo D. Vitullo
Centro de Estudios, Biomédicos, Biotecnológicos, Ambientales y Diagnóstico – CEBBAD –, Universidad Maimonides, Buenos Aires, Argentina

BACKGROUND: A central dogma of mammalian reproductive biology is that females are born with a finite, non-renewing pool of germ cells, all of them arrested in meiosis I (oocytes) and enclosed within follicles. In 2004, studies in mice challenged this dogma. It was concluded that the adult mouse ovary retains rare female germ cells or oogonia stem cells (OSCs) that can potentially generate oocytes de novo, a situation already described in prosimian since the 1970s´. More recently, in 2012, Tilly and coworkers identified and isolated OSCs from ovaries of reproductive-age women. Whether or not OSCs remain active in the adult mammalian ovary is a matter of current debate with studies showing evidence for and against oogenesis de novo. The South American plains vizcacha, L. maximus, is a hystricognathe rodent that shows the highest ovulation rate described for a mammal. Females release 400 to 800 oocytes in each estrus cycle accompanied by a considerable number of non-ovulated oocytes remaining inside luteinizing follicles. Moreover, oogenesis doesn´t stop during gestation; an ovulatory process takes place at mid-gestation with massive formation of secondary corpora lutea, and reproductive life spans over 10 years. In such a dynamic ovary, oogenesis de novo may well account for the permanent rebuilding of tissue organization and germ cell supply.
OBJECTIVE: To search for OSCs throughout the reproductive cycle in the adult ovary of L. maximus by expression analysis of primordial germ line markers.
MATERIAL AND METHODS: This study was reviewed and authorized by the institutional Committee on the Use and Care of Experimental Animals. A total of 25 adult ovaries belonging to non-pregnant ovulating females (OF; N=5); females at early-(EG; N=5), mid-(MG; N=5) and late-gestation (LG; N=5), and post-partum females (PP; N=5) were studied. All samples were processed by immunohistochemistry, immunofluorescence, western blot (WB) and real time PCR (qPCR) for DDX4, IFITM-3, STELLA, BLIMP-1, DAZ-L and OCT-4.
RESULTS: Pluripotency marker OCT-4 was strongly detected in surface epithelium and clusters of cells inside the ovary, especially in LG and PP ovaries, and confirmed by western blot and qPCR. Germ cell markers DDX4 and DAZ-L were expressed in cytoplasm of oocytes contained in primordial follicles in all groups. Both germ cell markers were observed in clusters of oocytes in PP period. IFITM-3 and STELLA expression had a membrane and cytoplasmic localization, respectively, and were associated especially with the surface epithelium and the tunica albuginea. The WB and qPCR showed a slight increase in LG and PP ovaries. BLIMP-1 showed a nuclear distribution in some cells associated to the surface epithelium. It was confirmed by WB and qPCR.
CONCLUSION: These results support the existence of potential OSCs in the mature ovary of L. maximus by showing cells expressing pluripotency and germ cell-specific markers associated to the surface epithelium and in cell clusters inside the ovary. It is worth to note that cells expressing OSCs markers are organized in clusters especially in LG and PP females which need to reorganize the ovarian reserve for the next reproductive season.

GERM CELL PROFILING REVEALS MOLECULAR SIGNATURES

Jia Hui Ng
Genome Institute of Singapore, Singapore, Singapore

Germ cells are unipotent cells that give rise to mature gametes. In the developing embryo, germ cells undergo genome-wide reprogramming that erases and also re-establishes DNA methylation and certain histone marks. Remarkably, germ cells retain the plasticity to acquire pluripotency *in vitro* if given the appropriate culture conditions. While it is known that early fetal germ cells express some pluripotency genes such as *Pou5f1*, the epigenome of germ cells is not well understood. Here, we performed transcriptional profiling and chromatin immunoprecipitation coupled with high-throughput sequencing (ChIP-Seq) on fetal germ cells that were purified from mouse embryonic gonads. Our data shows that the E11.5 germ cells express many pluripotency-related genes that are soon downregulated by E15.5. Comparison of the active histone mark H3K27ac also reveals *cis*-regulatory regions that are similarly and differentially marked in germ cells and pluripotent mouse embryonic stem cells (ESCs). Interestingly, germ cells share many bivalent sites (marked by both H3K4me3 and H3K27me3) with ESCs, with a greater overlap than when compared to the other cell types. We also observed classes of genomic regions that are marked by the repressive H3K27me3 histone modification in germ cells only and are enriched for retrotransposon repeats.

Further study of these germ cell transcriptional and epigenetic features may provide clues to the regulatory mechanisms that define germ cells.

W-2424

TRANSCRIPTIONAL REGULATION OF OVARIAN GERMLINE STEM CELL DIFFERENTIATION IN MAMMALS BY STEROID HORMONE SIGNALING

Chonthicha Satirapod, Ning Wang, Yvonne A. R. White, Dori C. Woods, Jonathan L. Tilly
Obstetrics and Gynecology, Massachusetts General Hospital, Boston, MA, United States

Recent studies show that adult mammalian ovaries possess germline or oogonial stem cells (OSCs) that generate oocytes *in vitro* and fertilization competent eggs *in vivo*. Genetic mouse models confirm OSC differentiation activity in adult ovaries and reveal that temporal disruption of this process causes a reversible reduction in oocyte numbers. These data indicate that, contrary to the longstanding belief mammalian females are born with a fixed pool of oocytes, maintenance of the adult ovarian reserve requires active input of new oocytes from OSCs. However, the molecular mechanisms regulating OSC activity are not known.
Steroid hormones coordinate many facets of mammalian reproduction, including the reproductive cycle in adult females. This cycle consists of an estrogen (E2)-dominant follicular phase and progesterone (P4)-dominant luteal phase. Our work and work from others show that oocyte numbers fluctuate during reproductive cycle, with lower numbers of oocytes observed during the follicular phase. Interestingly, a meiosis-initiating gene, *stimulated by retinoic acid gene 8* (*Stra8*), is also more frequently detected during this stage, suggesting a possible ongoing process of meiotic differentiation of OSCs to replenish the waning oocyte pool during each reproductive cycle. Here we show that E2 and P4 interact to regulate OSC differentiation by transcriptionally modulating expression of *Stra8*. E2 treatment of adult female mice leads to a rapid expansion of oocyte numbers accompanied by *Stra8* activation, and these effects can be blocked by P4. Mechanistic studies show that OSCs express estrogen receptor α (ERα) and progesterone receptor (PR) but not estrogen receptor β (ERβ). Importantly, ERα rapidly occupies the *Stra8* promoter on a putative estrogen response element (ERE) upon E2 treatment, supportive of ERα-mediated direct transcriptional activation of *Stra8* downstream of E2 signaling. Genetic studies confirmed a central role for ERα in mediating E2-induced OSC differentiation in that the adult oocyte pool in *ERα* knockout (*ERαKO*) mice failed to increase in number following E2 treatment; by comparison, *ERβ* knockout (*ERβKO*) mice responded to E2 like wild-type mice. In addition, while *ERαKO* mice show no developmental defects in embryonic germ cell differentiation nor in endowed oocyte numbers at birth, adult *ERαKO* mice exhibit a diminished oocyte reserve and a lower level of *Stra8* expression compared with age-matched wild-type and *ERβKO* mice. Notably, treatment of adult wild-type mice with ER antagonists, fulvestrant or raloxifene, also caused a significant depletion of the oocyte pool, although this depleted oocyte pool spontaneously rebuilt to its normal size after the cessation of ER antagonist treatment. Thus, through both genetic and pharmacological approaches, E2 signaling appears to play a crucial role in mediating OSC differentiation and oocyte renewal in adult mouse ovaries.
Collectively, our findings uncover a dynamic role for steroid hormone signaling in regulating mammalian OSC activity and consequently the size of oocyte pool during female reproductive cycle. Of immediate clinical relevance, these studies suggest that the potential effects of ER modulators, such as selective estrogen receptor modulators (SERMs) which are received by patients worldwide for various therapeutic purposes, on OSC function and the ovarian oocyte reserve should be considered.

W-2431

TARGETED ABLATION AND LINEAGE TRACING MOUSE MODELS CONFIRM OOCYTE RENEWAL IN POSTNATAL MAMMALIAN OVARIES

Ning Wang, Chonthicha Satirapod, Jonathan L. Tilly
Obstetrics and Gynecology, Massachusetts General Hospital, Boston, MA, United States

Contrary to the common belief that mammalian females are born with a fixed pool of oocytes, past studies in mice show that oocyte numbers remain remarkably stable during young adulthood despite of a large number of oocytes being removed by atresia and ovulation after growth activation. This suggests the possible existence of an active oocyte renewal process in adult ovaries that may involve germline stem cells (GSCs). Such a notion is further bolstered by the identification and recent isolation of a rare population of mitotically active germ cells in ovaries of adult female mice and of reproductive age women. These putative GSCs, or oogonial stem cells (OSCs), possess the ability, at least in mice, to generate functional eggs upon transplantation into recipient ovaries. However, experimental evidence supporting oocyte renewal from precursor cells, e.g., OSCs or their progeny, under normal physiological conditions is missing.

Meiosis can be viewed as a stem cell differentiation process unique to the germ line. *Stimulated by retinoic acid gene 8* (*Stra8*) is a germ cell-specific gene transiently expressed during a narrow window of time associated with meiotic initiation in differentiating GSC progeny of both sexes. *Stra8* is absent in undifferentiated GSCs and in mature germ cells such as sperm and oocytes. Recently, we showed that *Stra8* activation occurs in adult ovaries and often precedes increasing oocyte numbers, suggesting that OSCs, like other GSCs, activate *Stra8* to enter meiosis. This information has allowed us to develop a novel suicide gene transgenic (sg-Tg) mouse line in which the *Stra8* promoter drives expression of *Herpes simplex virus thymidine kinase* (*HSVtk*). In this line, Stra8+ germ cells generated by OSCs to produce new oocytes can be selectively ablated by exposure to ganciclovir (GCV). We show that the oocyte pool in ovaries of adult sg-Tg mice declined 44% after treating mice with GCV for 21 days, representing a loss of around 80 oocytes not being added to each ovary per day. OSCs do not express *Stra8* and were intact during GCV treatment. Thus, once the GCV-based ablation of Stra8+ germ cells was ceased, oocyte numbers spontaneously regenerated to their normal level as oogenesis resumes from OSCs. Importantly, this reversible oogenic failure in adult ovaries paralleled an expected reversible spermatogenic failure in adult testes when Stra8+ germ cells were temporally ablated using GCV. Interestingly, although OSCs are still present in aged ovaries, ablation of Stra8+ germ cells did not cause a change in oocyte numbers in older mice, indicating an absence of oocyte renewal during ovarian aging. To confirm these findings, we also developed an inducible lineage-tracing mouse model (*Stra8-R26R*) to genetically and permanently label with YFP any new oocytes being formed from OSCs during doxycycline (Dox) induction. After feeding adult female *Stra8-R26R* mice with Dox for 21 days, we observed a chimeric pool of follicles containing both YFP+ and YFP-negative oocytes. In addition, follicles containing YFP+ oocytes were observed at both resting and growing stages, indicating adult-derived oocytes mature normally.

Taken together, our studies firmly establish new oocyte production from OSCs undergoing meiotic commitment through *Stra8* activation, and demonstrate that oocyte renewal is required for the maintenance of the adult ovarian reserve in mammals. Our data also indicate that a progressive decline of OSC activity contributes to oocyte loss and ovarian aging.

RENAL TUBULAR LIKE CELLS GENERATED FROM MURINE GERMLINE CELL DERIVED PLURIPOTENT STEM CELLS PROTECT KIDNEY FROM ISCHEMIC INJURY

Letizia De Chiara[1], Sharmila Fagonee[1], Andrea Ranghino[2], Stefania Bruno[1], Giovanni Camussi[2], Emanuela Tolosano[1], Lorenzo Silengo[1], Fiorella Altruda[1]

[1]Department of molecular biotechnology and health sciences, Molecular Biotechnology Center, Torino, Italy, [2]Department of Internal Medicine, University of Turin, Torino, Italy

Spermatogonial Stem Cells are unipotent stem cells located on the basal membrane of the testis and continuously generate differentiating daughter cells for production of haploid spermatozoa. In vitro Spermatogonial Stem Cells are able to switch to pluripotent cells, the Germline-cell Derived Pluripotent Stem Cells (GPSCs). The conversion toward pluripotent state occurs spontaneously without transduction of reprogramming factors. GPSCs share many features with Embryonic Stem Cells, as are able to self-renew and differentiate into derivatives of all three germ layers. Moreover, GPSCs have a great plasticity, being able to differentiate in vitro into functional cardiomyocytes, neurons and hepatocytes. To investigate if GPSCs can be differentiate into renal tubular cells we devised a new

protocol to induce renal epithelial differentiation and successfully obtained GPSCs derived tubular-like cells (GTCs). GTCs were functional in vitro as demonstrated through Transepithelial Electrical Resistence (TEER) analysis. To investigate whether GTCs could protect against renal failure we studied a model of kidney ischemia/reperfusion injury. Soon after ischemic damage mice were injected with GTCs (treated group) or vehicle (control group). We found that GTCs were able to home to renal parenchyma. GTCs-treated mice showed reduced oxidative stress, apoptosis and cortical damage associated to a significant up-regulation of the anti-oxidant enzyme heme oxygenase (HO)-1.Mice treated with GTCs were also protected from chronic renal disease development as demonstrated by lack of fibrosis and decreased inflammatory infiltrate six weeks after ischemic injury.
In conclusion, we report for the first time that GPSCs can be differentiated into renal tubular-like cells and that these cells are functionally active in vivo protecting kidney from ischemic damage. This finding demonstrates the great plasticity of GPSCs and open the possibility to take advantage of GPSCs in regenerative cell therapy.

ANALYSIS OF HUMAN PARTHENOGENETIC IPS CELLS IDENTIFIES A NOVEL REGULATION OF ONCO-MICRORNA-371-3 IN TESTICULAR GERM CELL TUMORS

Yonatan Stelzer, Ido Sagi, Nissim Benvenisty
Genetics, The Hebrew University of Jerusalem, Jerusalem, Israel

Parental imprinting is a form of parent-of-origin epigenetic marking inherited from the gametes, which restricts asexual reproduction in placental mammals. Imprinted genes are expressed in a monoallelic fashion thus rendering them highly susceptible to genetic and epigenetic perturbations, potentially resulting in transformation and disease. Indeed, loss-of-imprinting in several genes (e.g., H19, IGF2 and MEST) has been correlated with different types of malignancies such as Wilm's tumor, colorectal neoplasia and lung cancer. Nevertheless, the causative role of imprinting in tumorigenesis is still poorly understood, so that the precise mechanisms by which imprinted genes might contribute to tumorigenicity remain to be elucidated. In this study we demonstrate that the onco-microRNA-371-3 are highly expressed in our established human parthenogenetic iPS cell lines, which harbor only maternal alleles. RNA deep sequencing analysis enabled the identification of a novel paternally expressed gene, transcribed in an antisense orientation to the onco-microRNA-371-3. We further demonstrated that the antisense transcript inhibits the expression of its corresponding microRNAs, thus indicating to a novel form of microRNA regulation in the human genome. As microRNA-372-3 were shown to play an oncogenic role in testicular germ cell tumors, we studied the involvement of its antisense transcript in these cells. Our results suggest that hypermethylation leading to loss-of-expression of the imprinted antisense transcript, contributes to tumorigenic transformation by affecting down-stream targets such as LArge Tumor Suppressor homolog 2 (LATS2). Furthermore, we could demonstrate that the novel imprinted transcript may play a tumor suppressive role, as its over-expression in tumor cells results in cell growth arrest and apoptosis. In conclusion, we report the involvement of a novel imprinted gene in testicular germ cell tumors, thus demonstrating the potential effect of loss-of-imprinting on tumor transformation. We also describe a novel form of microRNAs regulation in the human genome, suggesting a complex cross-talk in cancer and early embryogenesis between oncogenic-microRNAs and their tumor-suppressor antisense transcript.

HUMAN UMBILICAL CORD BLOOD-DERIVED MESENCHYMAL STEM CELLS EXPRESSING BDNF ENDOGENOUS NEUROGENESIS IN AN ISCEHMIC STROKE MODEL

Changhyun Jeong, Seong Muk Kim, Chung Heon Ryu, Sin-Soo Jeun
The Catholic University of Korea, Seoul, Korea, Republic of

Numerous studies have reported that mesenchymal stem cells (MSCs) can ameliorate neurological deficits in ischemic stroke models. Among the various hypotheses that have been suggested to explain the therapeutic mechanism underlying these observations, neurogenesis is thought to be critical. To enhance the therapeutic benefits of human umbilical cord blood-derived MSCs (hUCB-MSCs), we efficiently modified hUCB-MSCs by introduction of the brain-derived neurotrophic factor (*BDNF*) gene via adenoviral transduction mediated by cell-permeable peptides, and investigated whether *BDNF*-modified hUCB-MSCs (MSCs-BDNF) contributed to functional recovery and endogenous neurogenesis in a rat model of middle cerebral artery occlusion (MCAO). Transplantation of MSCs induced the proliferation of 5-bromo-2'-deoxyuridine (BrdU)-positive cells in the subventricular zone. Transplantation of MSCs-BDNF enhanced the proliferation of endogenous neural stem cells more significantly, while suppressing cell death. Newborn cells differentiated into doublecortin (DCX)-positive neuroblasts and Neuronal Nuclei (NeuN)-positive mature neurons in the subventricular zone and ischemic boundary at higher rates in animals with MSCs-BDNF compared with treatment using solely phosphate buffered saline (PBS) or MSCs. Triphenyltetrazolium chloride staining and behavioral analysis revealed greater functional recovery in animals with MSCs-BDNF compared with the other groups. MSCs-BDNF exhibited effective therapeutic potential by protecting cell from apoptotic death and enhancing endogenous neurogenesis.

SERUM STARVED ADIPOSE DERIVED STROMAL CELLS AMELIORATE RAT CRESCENTIC GLOMERULONEPHRITIS BY PROMOTING IMMUNOREGULATORY MACROPHAGES

Kazuhiro Furuhashi, Naotake Tsuboi, Yiqin Shi, Hangsoo Kim, Takayuki Katsuno, Takenori Ozaki, Seiichi Matsuo, Shoichi Maruyama
Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan

Introduction: Glomerular crescents determine renal prognosis in patients with rapidly progressive glomerulonephritis, however efficient therapeutic approach to regulate crescent formation has not emerged since diverse leukocyte subsets contribute to the lesion. We have reported that adipose
tissue-derived stem cells (ASC) promoted regeneration in a rat model of acute kidney injury. More recently, we have shown that ASC more strongly modulate T-cell immune reaction than bone marrow derived mesenchymal stem cells (BM-MSC). In the present study, we examined the renal protective effects of ASC focusing on their immunomodulatory properties in anti-glomerular basement membrane glomerulonephritis (anti-GBM GN) leading severe crescentic formation.
Methods: Necrotizing crescentic glomerulonephritis was induced in WKY rats by intraperitoneal injection of anti -GBM mAb, which closely resembles to nephritis in human Goodpasture disease. Renal function and histology were assessed in animals treated with ASC or BM-MSC. To evaluate ASC-driven functional M2 polarization in macrophage, we cultured peritoneal macrophages with ASCs or BM-MSC. For the evaluation of LASC-derived soluble factors in macrophage M2 conversion, PGE2 synthesis and IL-6 signaling in co-culture medium of macrophages with LASC were inhibited by pharmaceutical compounds or neutralizing antibody for respective receptors.
Results: ASC administered systemically to rats had a significant preventive effect against renal injury that was accompanied by a considerable decrease in proteinuria, crescent formation, and infiltration by glomerular leukocytes, including neutrophils, CD8+ T cells, and CD68+ macrophages. Interestingly, LASC increased the number of glomerular CD163+ macrophages known as immunoregulatory M2 macrophages, while this effect was not observed in BM-MSC. IL-10 concentration in renal cortex from diseased rat was higher in ASC group than in control group. In vitro co-culture system clearly demonstrated that ASC, but not BM-MSC, directly turned macrophage into M2 phenotype. Moreover, these effects of ASC were more prominent in LASC than HASC. Administrated ASCs were scattered in multiple organs and number of ASC in diseased glomeruli was 1.5/glomerulus/cross section without any difference between HASC and LASC, but this would be efficient since individual LASC could polarize around 200 macrophages to M2 phenotype in vitro. These results suggest that LASC recruited into diseased glomerulus make stronger effect on macrophages for protection of glomerular injury and crescent formation than HASC. Moreover pharmaceutical ablation of PGE2 production or neutralization of IL-6 in the co-culture medium significantly reversed LASC-mediated macrophage conversion.

Conclusion: We found that LASC-derived IL-6 and PGE2 induce CD163+ macrophages in our *in vitro* co-culture system. ASC exerted profound immunoregulatory properties especially on macrophages and ameliorated glomerular injury in rat anti-GBM glomerulonephritis model. In human immunosuppressive therapy such as corticosteroid and cyclophosphamide remains the prevailing therapy for CGN, but this is often restricted for their adverse effect such as infection and agent cytotoxicity. Therefore, LASC administration would be desirable therapeutic approach to improve prognosis of anti-GBM GN patients.

W-3003

MESENCHYMAL STEM CELL THERAPY AMELIORATES DEXTRAN SODIUM SULFATE-INDUCED COLITIS IN MICE BY REGULATING BONE MARROW NICHE CELLS AND HEMATOPOIETIC STEM CELLS

Kanna Nagaishi[1], Hiroyuki Isshiki[1], Yoshiaki Arimura[1], Yasuyoshi Naishiro[1], Mineko Fujimiya[1], Kozoh Imai[2], Ysuhisa Shinomura[1]

[1]Sapporo Medical University, Sapporo, Japan, [2]Tokyo University, Tokyo, Japan

Background/Aim: Two major functions of mesenchymal stem cells (MSCs) are repair and regeneration of target tissue and immune-modulatory function through production of trophic factors, cell supplementation, and cell-cell interaction. We have shown that MSC therapy reduced the severity of colitis in mice. In spite of only few numbers of MSCs distributed in colonic tissue, MSCs were engrafted in bone marrow and its amount seemed to be amplified. Hematopoietic stem cells (HSC) are known to differentiate into mature hematopoietic cells, which are source of inflammatory cells, and its quiescence is regulated by niche cells in bone marrow. The most quiescent HSC known as long term reconstitute HSC (LT-HSC) are cross-talking with niche cells by abundant molecules and maintain its functions. In this study, we investigated whether the hyper-cytokinemia in colitis could induce niche cell perturbation, whether abnormal niche cells secondary affected HSCs to provide excessive mature inflammatory cells in colonic tissues, and whether MSC therapy could reverse niche cell perturbation and subsequent abnormality of HSCs in bone marrow.
Methods: MSCs were administered to dextran sodium sulfate (DSS)-induced colitis mice. Therapeutic effects of MSCs were analyzed by pathological findings of colonic tissues. Kinetics and molecular profile of Nestin-positive niche cells (Nes^+ cells) in bone marrow of control mice, DSS colitis-induced (DSS) mice and MSC-treated DSS colitis-induced (DSS-MSC) mice were investigated. HSCs were fractionated by the differentiation and analyzed the expression of functional molecules. Nes^+ cells isolated from control mice and DSS mice were co-cultured with LT-HSC derived from DSS mice respectively to clarify the effect of niche cell replacement for the abnormality of HSCs. Furthermore, niche cells isolated from DSS mice were cultured with or without MSCs *in vitro* to investigate the effect of MSCs to abnormal niche cells.
Results; The number of Nes^+ cells in bone marrow and colony forming unit ability were remarkably reduced in colitis mice and were recovered with MSC therapy. Expression of Wnt5a, stem cell factor (SCF) and stromal cell-derived factor-1 (SDF1) in Nes^+ cells were remarkably decreased in DSS mice, while the reduction was prevented in DSS-MSC mice. Expression of CXCR4 in LT-HSC was reduced in DSS mice compared to control mice, which were up-regulated by replacement of abnormal niche cells *in vitro*. This result was similar to the

expression profile of LT-HSCs in DSS mice and control mice *in vivo*. Expression of Osteopontin in Nes^+ cells was reduced
in DSS mice compared to control mice, which were recovered by exposed to MSCs *in vitro*. This result was similar to the
expression profile of Nes^+ cells in DSS mice and control mice *in vivo*. Finally, expressions of frizzled family receptor 4 (Fzd4), beta-catenin and Tie2 in LT-HSCs were extremely down-regulated in DSS mice and were prevented in DSS-MSC mice.
Conclusion: HSCs are supported by niche cells by various factors, such as Wnt signaling, adhesion molecule, chemokines and growth factors. These are down-regulated in colitis and affected to the interaction with HSCs, which resulted in excessive supply of activated inflammatory cells in colonic tissue by losing quiescence and excessive mobilization from niche. MSC therapy has an ability to suppress severe colitis via regulation of niche function in the bone marrow. These findings may provide the new target of IBD therapy.

W-3004

MESENCHYMAL STEM CELLS HOME TO OCULAR SURFACE AND SUPPRESS ALLOIMMUNITY IN CORNEAL TRANSPLANTATION

Sunil Chauhan, Masahiro Omoto, Reza Dana
Department of Ophthalmology, Harvard Medical School, Schepens Eye Research Institute, Massachusetts Eye and Ear, Boston, MA, United States

Purpose: To investigate whether systemically-injected host mesenchymal stem cell (MSC) can home to the transplanted cornea, suppress induction of alloimmunity, and promote allograft survival.
Methods: MSC ($CD45^-CD34^-SCA1+CD29+$) were generated from the bone marrow of wild-type BALB/c or GFP+ C57BL/6 mice, and $1x10^6$ cells were intravenously injected to allografted recipients 2h after surgery. To track the homing of GFP+ MSC (C57BL/6), corneal grafts from BALB/c (H-2d) mice were transplanted onto C57BL/6 (H-2b) recipient mice. MSC homing to the corneas was examined at day 3 post-transplantation by immunohistochemistry. To investigate the effect of MSC on alloimmunity and graft survival, corneal grafts from C57BL/6 mice were transplanted onto BALB/c recipient mice, and then wild-type BALB/c MSC were injected. Frequencies of alloreactive IFNγ+ T cells were analyzed at day 14 post-transplantation using the ELISPOT assay. Frequencies of mature CD11C+MHC-II+ antigen-presenting cells (APC) were analyzed by flow cytometry. Graft survival was evaluated by slit-lamp biomicroscopy weekly up to 8 weeks.
Results: Intravenously injected GFP+MSC were found in abundance in the transplanted cornea, but not in the ungrafted (contralateral) cornea. The frequencies of mature CD11C+MHC-II+ antigen-presenting cells were substantially decreased in the corneas (50.2% vs. 76.7%) and draining lymph nodes (4.4% vs. 8.4%) of MSC-injected allograft recipients compared to control group. The draining LN of MSC-injected allograft recipients showed significantly lower frequencies allosensitized IFNγ-secreting T cells compared to the control group (p=0.023). Allograft survival rate was significantly (~2-fold) higher (p = 0.03) in the MSC-injected recipients (80%, n=12) compared to the non-MSC injected group (40%, n =10).
Conclusion: Our data demonstrate that systemically-administered MSC specifically home to transplanted corneas and promote allograft survival by inhibiting APC maturation and induction of alloreactive T cells. These data suggest that host MSC exert immunomodulatory functions in corneal transplantation and may be used to prolong transplant survival.

BASIC STUDIES USING BONE MARROW-DERIVED MESENCHYMAL STEM CELLS FOR THE DEVELOPMENT OF A LESS INVASIVE LIVER REGENERATION THERAPY FOR LIVER CIRRHOTIC PATIENTS

Taro Takami[1], Shuji Terai[1], Luiz Fernando Quintanilha de Mesquita[1], Haruko Tanimoto[1], Koichi Fujisawa[2], Naoki Yamamoto[3], Isao Sakaida[1]

[A]Department of Gastroenterology and Hepatology, [B]Center for Reparative Medicine, [1]Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan, [2]Yamaguchi University Health Administration Center, Yamaguchi University, Yamaguchi, Yamaguchi, Japan

Background and Objectives: We have developed an autologous bone marrow cell infusion (ABM*i*) therapy that is a safe and efficient liver regeneration therapy for liver cirrhotic patients using non-cultured autologous whole bone marrow (BM) cells. However, this therapy involves BM aspiration under general anesthesia and is not indicated in patients for whom general anesthesia must be avoided. We have therefore started to develop a less invasive liver regeneration therapy that uses autologous BM-derived mesenchymal stem cells (BM-MSCs) and requires small amounts of autologous BM aspirated under local anesthesia. Recently, it has been demonstrated that MSCs show antioxidant activity, which may be important in the treatment of liver diseases, as oxidative stress plays an important role in liver disease development. Here, we attempted to test MSCs in liver regeneration and reveal the underlying mechanisms, particularly with regard to antioxidant activity.
Methods: Cultured BM-MSCs were analyzed based on morphology, flow cytometry and differentiation protocols. To assess effects of these cells on liver injury in vivo, we systemically infused BM-MSCs into NOD-SCID cirrhotic mice. Liver fibrosis and hepatic stellate cell (HSC) activation were assessed by Sirius red staining and immunohistochemistry, respectively. Injury serum markers such as **alanine transaminase (ALT), aspartate transaminase (AST) and lactate dehydrogenase (LDH), beyond total antioxidant activity were evaluated.** To confirm the protective effects against oxidant conditions, we used hydrogen peroxide (H_2O_2) or thioacetamide (TAA) in order to induce oxidative stress conditions in vitro. We then quantified cellular reactive oxygen species (ROS) and enzymes related to oxidative stress resolution in HSCs and hepatocytes co-cultured with BM-MSCs.
Results: We confirmed that our cells showed MSC characteristics. They were adherent to plastic, positive for CD73/CD90/CD105 and negative for CD45/CD11b, and were able to differentiate into adipocytes and osteocytes. In NOD-SCID mice, they were able to reduce fibrosis ($p<0.05$) and hepatic αSMA-positive area ($p<0.05$). In addition, mice treated with BM-MSCs showed lower levels of ALT ($p<0.05$) and AST ($p<0.05$), and higher total antioxidant activity ($p<0.001$). HSCs co-cultured with BM-MSCs showed lower levels of ROS-signals ($p<0.05$), consistent with up-regulated expression of heme oxygenase-1 ($p<0.01$) and superoxide dismutase-3 ($p<0.001$). Moreover, we confirmed that hepatocytes co-cultured with MSCs had lower levels of ROS ($p<0.001$), and higher expression of NF-E2-related factor 2 ($p<0.05$) and glutathione *S*-transferase ($p<0.01$).
Conclusions: These results demonstrate that infused BM-MSCs are involved in the improvement of liver injury through stabilization of redox homeostasis, which strongly indicates the possibility of a less invasive liver regeneration therapy for liver cirrhotic
patients based on infusion(s) of BM-MSCs.

BAROREFLEX SENSITIVITY AND CARDIAC FUNCTION IN RATS WITH HEART FAILURE TRANSPLANTED WITH ALLOGENEIC MESENCHYMAL STEM CELLS.

Sharon D B V Morais[1], Renata M. Lataro[1], Carlos Alberto Aguiar Silva[1], Luciano F L Oliveira[1], Eduardo E V Carvalho[1], Christiane Becari[1], Marcus Vinicius Simões[1], Lindolfo da Silva Meirelles[2], Hélio Cesar Salgado[1], Rubens Fazan Jr.[1]

[1]Physiology, Medicine School of Ribeirão Preto / University of São Paulo, Ribeirão Preto, Brazil, [2]Lutheran University of Brazil, Canoas, Brazil

Background. Patients with heart failure induced by myocardial infarct (MI) have impaired baroreflex function, which is an important risk for life threatening. The baroreflex plays an important modulatory role on heart rate

(HR), cardiac output, myocardial contractility and regional distribution of blood flow. Therapy with mesenchymal stem cells (MSC) has shown promising results after MI in either patients or experimental animals, showing pro-angiogenic, anti-fibrotic and immunomodulatory effects. The aim of this study was to evaluate the effect of MSC on baroreflex sensitivity and cardiac function in rats with heart failure induced by MI.
Methods and Results. Male Wistar rats (250-320g) were treated, intravenously, with MSC (N=4) or saline (N=5) 1 week after surgical ligation of left coronary artery. Sham-operated (non-infarcted, N=5) control rats were also evaluated. Transplanted MSC were characterized according to criteria of the International Society for Cellular Therapy. The size of MI was evaluated by single photon emission computed tomography (SPECT) 2-3 days after coronary ligation and were found similar among infarcted rats (51±1%). Heart function (left ventricle ejection fraction) was assessed by isotopic cardiac ventriculography before and one month after administration of MSC. After the second ventriculography, animals underwent 12 lead electrocardiographic recording and were implanted with catheters into femoral artery and vein. After 24h of vessel catheterization, conscious freely moving rats had their basal arterial pressure (AP) and HR recorded. Following, phenylephrine (8 μg/kg, iv) was used to induce an acute rise in AP and baroreflex mediated fall in HR. The ratio between changes in HR and AP was used as an index of baroreflex sensitivity. At the end of the experiments, the animals were killed and the hearts were collected for histopathological analysis. The extension of the infarct was found smaller in rats treated with MSC (36±3%) as compared with the saline treated counterparts (47±2%). Ventricular performance was markedly impaired after MI (42±3.4% control, 15±2.4% before saline injection and 17±1.9% before MSC injection), but MSC did not improve cardiac function (51±2% control, 16±1% saline and 20±4% MSC). Interstitial collagen was 10±1% in sham operated control rats. Infarcted rats showed an increase in interstitial collagen (15±2%), that was not observed in those treated with MSC (11±1%). Baroreflex sensitivity was lower after MI (1.10±0.1 bmp/mmHg); nevertheless, infarcted rats that received MSC presented baroreflex sensitivity similar to non-infarcted control rats (1.74±0.2 vs. 1.80±2 bpm/mmHg). QT and QTc intervals were lengthened by MI, while MSC did not affect this parameter (iQT: 85 ± 2.4ms control vs. 97 ± 1.4ms saline and 97 ± 0.8ms MSC; iQTc: 197 ± 3.2ms control vs. 228 ± 6.8ms saline and 223 ± 4.5ms MSC).
Conclusion: Altogether, the results show, after one month of treatment, that MSC therapy reduced the extension of the infarction and the interstitial fibrosis in the surviving myocardial of the left ventricle, besides improving baroreflex sensitivity.

WEEKLY INTRAARTICULAR INJECTIONS OF SYNOVIAL MESENCHYMAL STEM CELLS DELAY CARTILAGE DEGENERATION THROUGH TROPHIC FACTORS IN A RAT OSTEOARTHRITIS MODEL

Nobutake Ozeki[1], Ichiro Sekiya[2], Kunikazu Tsuji[3], Tomoyuki Saito[4], Takeshi Muneta[1]
[A]Department of Joint Surgery and Sports Medicine, [B]Department of Cartilage Regeneration, [C]Global Center of Excellence Program, [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Orthopaedic Surgery, Yokohama City University, Yokohama, Japan

INTRODUCTION
Osteoarthritis is a degenerative joint disease associated with cartilage breakdown and inflammation of synovium. We previously reported that mesenchymal stem cells (MSCs) derived from synovium had a high proliferation and chondrogenic potential, and transplantation of synovial MSCs into a full-thickness cartilage defect promoted cartilage regeneration. In this study, we investigated whether intraarticular injections of synovial MSCs delayed cartilage degeneration in a rat osteoarthritis model.
METHODS
Animals and surgery: Wild type male Lewis rats at 11-13 weeks were used. To induce osteoarthritis, anterior cruciate ligament was transected.
Weekly injections of synovial MSCs: From 1 week after the surgery, 1 x 10^6 syngenic synovial MSCs were injected into the knee joint every week (weekly group). The one shot group had only one injection of MSCs, and the control group had weekly injections of PBS alone. Both femoral and tibial cartilage were evaluated macroscopically and histologically at 5, 9, and 13 weeks after the surgery.

In vivo bioluminescent imaging (IVIS): To chase the injected MSCs, IVIS was used to detect photons from synovial MSCs derived from luciferase transgenic rats.
Detection of LacZ expression: To clarify cell distribution of injected cells, X-Gal staining was evaluated after injection of synovial MSCs derived from LacZ transgenic rats ($LacZ^+$ MSCs).
Quantitative measure and gene expression of the engrafted synovial MSCs: For a quantitative measure of the engrafted synovial MSCs, synovium of human MSCs(hMSCs) injected samples were compared to control by a quantitative RT-PCR assay specific for human β-actin. Control samples were prepared by adding various numbers of hMSCs to the synovium before homogenizing, extracted RNA. Additionally, gene expression of rat and human RNA was evaluated.
RESULTS
Weekly injections of synovial MSCs delayed cartilage degeneration. Macroscopic and histological observations for cartilages revealed cartilage lesions gradually progressed in the one shot group and in the control group, while cartilages in the weekly group appeared to be better throughout the study. The OARSI score for cartilage histopathology was significantly better in the weekly group at 9, and 13 weeks than in the other groups. Vascular formation in the infrapatellar fat pad increased in the control group, but it did not in the weekly group.
MSCs could be detected in the knee joint at all times when injected weekly. After a one shot injection, IVIS showed MSC-derived photons detected around the knee decreased within 14 days. When MSCs were injected weekly, they could be detected at all times.
Most MSCs adhered to the synovium and expressed TSG-6. One day after injection of $LacZ^+$ MSCs, dark blue areas for LacZ were observed mainly in the synovium macroscopically, and LacZ-positive cells could be confirmed in the synovium histologically. PCR analysis revealed that about 1 % of injected MSCs survived within synovium 1 day after injection, and expression of human TSG-6 was upregulated.
DISCUSSION
Weekly intraarticular injections of synovial MSCs delayed cartilage degeneration in a rat osteoarthritis model. One of the mechanisms to delay progression of osteoarthritis is considered to be due to the trophic effect of MSCs to suppress synovial inflammation. After injection of MSCs into the knee joint, they rapidly decreased. As osteoarthritis is a chronic and progressive disease, not a single injection, but periodical injections are recommended.

EXPOSURE OF MESENCHYMAL STEM CELLS OR CULTURED PROXIMAL TUBULE STEM CELLS TO A KIDNEY INJURY ENVIRONMENT INDUCES OXIDATIVE AND MITOCHONDRIAL STRESS

Jon D. Ahlstrom[1], Florian E. Toegel[2], Zhuma Hu[1], Ping Zhang[1], Christof Westenfelder[3]
[1]Medicine, VA medical center, Salt Lake City, UT, United States, [2]Nephrology, Harvard Medical School, Boston, MA, United States, [3]Physiology, University of Utah, Salt Lake City, UT, United States

Acute kidney injury (AKI) is a common and largely treatment-resistant syndrome in which complex mechanisms mediate injury and repair. Pre-clinical studies from our laboratory have led to a Phase I Clinical Trial in which Mesenchymal Stem Cells (MSCs) were administered to at-risk patients undergoing cardio-pulmonary bypass surgery to test the safety and preliminary efficacy of MSCs for the prevention of post-op AKI. It is well recognized that the changes in the “milieu interne” that result as a consequence of AKI adversely affect the function of distant organs in addition to the kidney. Hence, it is possible that the AKI environment into which the MSCs are placed in vivo could be harmful to the cells administered as a therapy. The objective of this present study was to explore the consequences of AKI on the cellular responses of MSCs, using a model of culturing rat MSCs or rat kidney cells (NRK cell line), in serum from rats with experimentally induced AKI. To confirm the relevance of our assay, we also compared our in vitro results with cells sampled from tissues and organs in vivo following AKI.
Exposure of MSCs or NRK cells to 10% AKI serum for 48 hours caused, compared to incubation with SHAM serum or animal sera obtained following nephrectomy (NPHX), the upregulation of anti-oxidant genes (catalase, HO-1), increased reactive oxygen species activity (CMH2DCFDA), higher mitochondrial membrane potential (TMRE), increased mitochondrial complex I activity, and reduced mitochondrial reserve capacity (Seahorse XF). Tissues collec-

ted from organs in vivo, such as the kidney, heart and lung, also showed a similar response, with increased HO-1 gene expression and higher mitochondrial membrane potential following AKI.
Summary: Exposure of MSCs to a kidney injury environment resulted in greater cellular oxidative and mitochondrial stress. This result required the presence of injured tissue, because at comparable levels of kidney dysfunction (AKI vs. NPHX), the stressful conditions were found in the AKI, and not the SHAM or NPHX environment. This indicates that the injured kidney per se generates signals that are traumatic for MSCs and other cells types.
In conclusion: These data identify yet inadequately understood pathogenic signals that are generated by the injured kidney, and whose nature, once defined, is expected to further advance our understanding of the acutely uremic state and how it affects renal and systemic cell biology and organ functions. In addition, these initial observations provide the basis for the development of therapeutic interventions that are both renoprotective and can overcome the negative effects of AKI.

Introduction
The immunomodulatory properties of Mesenchymal Stem Cells (MSC) are currently under investigation for their potential to treat autoinflammatory conditions. This includes acute lung injury (ALI), where, following a minimally traumatic insult, a rapid influx of inflammatory cells is accompanied by an increase in pro-inflammatory cytokines leading to disruption of the alveolar capillary interface, and ultimately resulting in alveolar oedema and respiratory failure. MSCs have been proposed for the management of ALI, where, following lung injury, administered MSC may arrest the progression of the inflammatory cascade and thus prevent the degeneration of lung function. Here, we hypothesised fetal MSC (fMSC) to attenuate inflammatory reactions of macrophages, and explored their utility in a murine model of smoke-induced ALI.
Methods
Following informed consent, fetal femurs were collected for isolation of fMSC after clinically-indicated termination of pregnancy. fMSC were characterised according to ISCT guidelines. An in vitro macrophage inflammatory assay was used to study the immonomodulatory mechanism of fMSC. Monocytes were derived from healthy human blood samples and exposure to Granulocyte-macrophage colony-stimulating factor (GM-CSF to yield macrophages. The macrophages were stimulated with LPS and fMSC were subsequently added and cytokine expression of IL-6, IL-8 and TNF-alpha were determined after 24h using ELISA. For evaluation of utility in the treatment of ALI, an immunocompetent murine model of ALI by smoke inhalation was generated. Lung injury at 24h was characterised by bronchio-alveolar lavage (BAL) cell counts and protein concentration, wet/dry ratio, cytokines (IL-6, MCP-1, KC, G-CSF and IP-10) and myeloperoxidase (MPO) analysis on lung tissues. Histological analysis of lung tissue was conducted to assess extent of lung damage. Treatment with 0.5x10^6 cells (cell passages 4-6) was introduced intratracheally between 1-2hr after smoke inhalation injury. BAL and lung tissue were collected at 24h and assayed for various lung injury parameters.
Results
fMSC incubated with stimulated macrophages demonstrated two-fold reduced TNF-alpha levels with no significant changes observed in IL-6 and IL-8 levels. These findings could be reproduced in a transwell set-up but not with MSC-conditioned medium, suggesting a primarily paracrine signalling mechanism with crosstalk. A murine model of smoke inhalation-induced ALI was generated, demonstrating increase in BAL cell counts, wet/dry ratio, cytokines and MPO as well as an increase in the histological lung injury index ($p<0.05$).Following treatment with MSC, reduc-

tion in BAL cell counts (4.1x10^5 vs 3.2x10^5 cells), protein concentration (198ug/ml vs 151ug/ml) and cytokine (G-CSF, IP-10) levels were observed.
Conclusion
The immunomodulatory properties of fMSC on inflammatory cells were studied, and shown to suppress TNF-alpha levels in a paracrine fashion. Thus, following administration to a murine model of smoke inhalation-induced ALI, fMSC were able to reduce lung injury. Taken together, our results suggest fMSC to exhibit anti-inflammatory properties, with potential applications in the management of autoinflammatory conditions.

MSC REGENERATIVE POTENTIAL; DOES DONOR AGE MATTER

Martha L. Arango, Paulette A. Conget
Facultad de medicina, Universidad Del Desarrollo, Santiago de Chile, Chile

In pre-clinical and clinical studies, it has been proved that the transplantation of multipotent mesenchymal stromal cells, also referred as to mesenchymal stem cells (MSCs), results in therapeutic effect. Currently there is no systematic information regarding whether donor age modify the regenerative potential of MSCs. Nevertheless, the following age-related changes have been shown: decline in the abundance, increase in senescent cell frequency, defeat of proliferation potential, reduction of immunomodulatory potential, and loss of in vivo bone formation potential.
Our aim was to compare the regenerative potential of syngeneic MSCs obtained from young (8-weeks-old), middle age (33-weeks-old) or elder (50-weeks-old) female donors. For this, two doses of MSCs (0.5 or 1x106) or two doses of medium conditioned by MSCs (1x or 6x) were administered subcutaneously around full thickness excisional splits of 6 mm diameter performed in the midline of 8-weeks-old male C57BL6 mice. Every two days after MSC transplantation, wound healing was assessed macroscopically (wound closure, retraction and scare formation) and microscopically (re-epithelialization, dermal-epidermal junction formation, granulation tissue formation, leukocyte infiltration, fibrosis and skin appendage structure regeneration).
As expected, wound closure was accelerated in cutaneous lesions that received MSCs or their conditioned medium, compared with lesions that received only the vehicle (8 vs. 12 days, respectively). Surprisingly, we found that MSCs and their conditioned medium obtained from young donors were the less efficient tools to fasten wound closure (50% at day 6-8 for young vs. day 4-5 for middle and elder). This difference was not overcome by increasing cell or medium doses. Also, we observed the administration of MSCs or their conditioned medium obtained from middle age or elder donors restrained leucocyte infiltration and fibrosis, and resulted in re-epithelialization, dermal-epidermal junction formation and appendage regeneration.
Our data prove that donor age modify the regenerative potential of MSCs and suggest that this might be due to changes in their paracrine factor secretion capability.
Supported by FONDECYT 11110009 to ML.A.

TRANSPLANTATION OF HUMAN AMNION-DERIVED MESENCHYMAL STEM CELLS IMPROVES SEVERE COLITIS VIA ATTENUATION OF MACROPHAGE ACTIVITY IN RATS

Shunsuke Ohnishi[1], Reizo Onishi[1], Ryosuke Higashi[1], Kenichi Yamahara[2], Michiko Watari[3], Waka Kobayashi[1], Takehiko Katsurada[1], Hiroshi Takeda[1], Naoya Sakamoto[1]
[1]Hokkaido University, Sapporo, Japan, [2]National Cerebral and Cardiovascular Center, Osaka, Japan, [3]Tenshi Hospital, Sapporo, Japan

Aims: Mesenchymal stem cells (MSCs) have been reported to be a valuable cell source in cell therapy, and bone marrow (BM) represents a major source of MSCs; however, there are several limitations when using BM-MSCs, including inadequate cell numbers and invasiveness. Recently, several studies have shown that MSC can be easily isolated from human amnion, and a large amount of cells can be obtained. We thus examined the therapeutic ef-

fects of transplantation of human amnion-derived MSCs (hAMSCs) in dextran sulfate sodium (DSS)-induced colitis in rats.
Methods: The Medical Ethical Committee approved this examination and all pregnant women gave written informed consent. Amnion was obtained at Cesarean delivery, and hAMSCs were isolated and expanded by digestion with collagenase, followed by culturing in uncoated plastic dishes. Severe colitis was induced in 7-week-old male Sprague-Dawley rats by administration of 8% DSS in drinking water ad libitum from day 0 to day 5. At day 1, hAMSCs (1×106 cells) were transplanted intravenously. Changes in body weight and disease activity index (DAI) were evaluated daily for 5 days. Rats were sacrificed on day 5, and the entire colon was extracted. Colon length, histological colitis score were evaluated, and mRNA expression of inflammatory mediators were measured by quantitative RT-PCR. Infiltration of monocytes/macrophages (CD68), neutrophils (myeloperoxidase (MPO)) and T cells (CD3) was investigated by immunohistochemistry. Effect of hAMSCs on induction of TNF-α from mouse macrophage cell line RAW264.7 by lipoplysaccahride (LPS) was evaluated with quantitative RT-PCR and ELISA.
Results: Transplantation of hAMSCs significantly ameliorated the DAI score, weight loss, colon shortening and histological colitis score. mRNA expression of TNF-α, IL-1β and MIF was significantly decreased in the rectum of hAMSC-treated rats. In addition, infiltration CD68-positive cells was significantly decreased in hAMSC-treated rats. Furthermore, expression of TNF-α mRNA and protein from RAW264.7 cells induced by LPS was significantly attenuated by co-culture with hAM-MSCs, or by culture with conditioned medium obtained from hAMSCs.
Conclusion: Transplantation of hAMSCs provided significant improvement in a rat model of severe colitis, possibly through inhibition of macrophage activity. AMSC would be considered as a new cell source for the treatment of severe colitis.

W-3015

BONE MARROW-DERIVED MESENCHYMAL STEM CELL THERAPY FOR SYSTEMIC ARTERIAL HYPERTENSION IN RATS.

Igor Oliveira Loss, Lucas Felipe Oliveira, Marcos Vinicius Silva, Thalles Ramos Almeida, Marcus Paulo Ribeiro Machado, **Valdo Jose Dias da Silva**
Biological Sciences, Triangulo Mineiro Federal University, Uberaba, Brazil

Previous data from our laboratory have demonstrated that allogenic transplantation of bone marrow mononuclear cells from spontaneously hypertensive rats (SHR) has reduced arterial blood pressure (ABP) around 25-30 mmHg for two consecutive weeks. The central aim of the present work was to examine the therapeutic effects of bone marrow-derived mesenchymal stem cell (MSC) transplantation previously cultivated *in vitro* on spontaneous arterial hypertension in SHR. Adult female SHRs (200 - 230g) were divided in two groups: SHR-MSC (n=8) and SHR-CON (control, n=8). The animals of each group have received respectively an intra-peritoneal injection of 5 millions MSCs (expanded until 5th passage) or vehicle solution (physiological saline). Systolic arterial pressure (SAP) and heart rate (HR) were monitored by means of tail occlusion method 5 days before and after treatment during 15 days. Following, for direct recordings of hemodynamic parameters, all animals were anesthetized with tribromoethanol (250 mg/kg, i.p.) and had their right femoral artery catheterized. After 24-48 hours of surgical recovering, ABP were recorded during 60 minutes, and at the end, after a new anesthesia session (urethane - 1,2g/Kg), a catheter was inserted into left common carotid artery for injection of doses of acetylcholine (3-25ηg/Kg) or sodium nitroprusside (0,5-4μg/Kg), in order to indirectly evaluate systemic endothelial function by means of depressor responses to endothelial-dependent and endothelial-independent vasodilators, respectively. At the end of the experimental protocol, all animals were euthanized and heart, lungs, kidneys, liver, spleen and skeletal muscle (gastrocnemius) were collected, rinsed in physiological saline, fractioned and frozen or fixed in formaldehyde. Heart weight was measured and fixed slides of skeletal muscle were processed for immunohistochemical labeling for CD31 in order to quantify muscle capillary vessels. Fixed slides of kidneys stained with hematoxylin/eosin were used to morphometric studies of renal glomeruli. Pieces of different organs from animals transplanted with MSCs were fractioned, collagenase-digested and cells previously labeled with DiI CM were counted using flow cytometry. Indirect and direct measurements of ABP have shown long lasting reduction (15 days) of tensional levels (around 15-20 mmHg), after i.p. administration of MSCs in SHR. In addition, MSC transplantation has also provoked increas-

ing in spontaneous baroreflex sensitivity and decreasing in ABP variability, as well as reduction in cardiac hypertrophy and glomerular Bowman space in treated animals. Endothelial dysfunction of SHR was not changed by MSC treatment. Searching for DiI CM positive cells in several tissues from transplanted animals have revealed minimal quantities of cells in lungs and kidneys. Taking all together, our findings seem to indicate a promising utilization of bone marrow-derived mesenchymal stem cell transplantation to treat systemic arterial hypertension. Despite the lack of mechanisms, a possible paracrine effect of MSC seems to be possible.

MESENCHYMAL PRECURSOR CELLS ATTENUATE THE DEVELOPMENT OF ENDOTHELIAL DYSFUNCTION IN AN OVINE MODEL OF COLLAGEN-INDUCED ARTHRITIS

Laura M. Dooley[1], Elizabeth A. Washington[1], Anwar M. Abdalmula[1], Peter Ghosh[2], Wayne G. Kimpton[1], Silviu Itescu[2], Simon R. Bailey[1]

[1]Faculty of Veterinary Science, The University of Melbourne, Parkville, Australia, [2]Mesoblast Ltd, Melbourne, Australia

Rheumatoid arthritis (RA) is a systemic autoimmune condition associated with increased risk of cardiovascular mortality. The chronic systemic inflammatory response is believed to accelerate the development of subclinical vascular lesions. The earliest detectable cardiovascular change in human RA is dysfunction of endothelial cells, characterised by reduced endothelium-dependent vasodilation. Our earlier studies have demonstrated that an ovine model of rheumatoid arthritis produces systemic endothelial dysfunction. Bone marrow-derived mesenchymal precursor cells (MPC) have been reported to possess immunomodulatory properties that may prove beneficial in autoimmune and chronic inflammatory conditions. The aim of this study was to determine if ovine MPC given early in the disease course of an ovine model of collagen-induced arthritis are able to improve clinical signs and attenuate the development of endothelial dysfunction.

Arthritis was induced in sixteen healthy adult merino sheep by administration of two subcutaneous injections of bovine type II collagen in Freund's adjuvant two weeks apart, followed by an intra-articular injection of bovine type II collagen into the left hock joint. One day following the intra-articular injection, sheep were administered either 150 million allogenic ovine MPCs intravenously (n=8), or saline only (n=8). Sheep were examined frequently to score clinical signs of arthritis. Lameness, swelling and pain on joint flexion were assessed. Plasma samples were collected at days 0, 1, 2, 3, 5, 7, 10 and 13 following treatment to characterise the systemic inflammatory response. Plasma fibrinogen was measured using the modified heat precipitation method at a commercial veterinary laboratory. All animals were culled two weeks following arthritis induction. Coronary arterial segments were mounted in a Mulvaney-Halpern wire myograph, pre-contracted then dilated with the endothelium-dependent dilator bradykinin (10-11M to 3x10-6M). Paired segments were dilated with the endothelium-independent dilator, sodium nitroprusside (SNP, 10-9M to 3x10-4M).

Sheep treated with MPCs demonstrated significantly lowered clinical arthritis scores over the 13 days following treatment ($p<0.05$, unpaired t-test). Coronary arteries from RA sheep treated with MPCs demonstrated a significantly greater maximal relaxation to bradykinin when compared to untreated RA sheep (255.5 ±9.1 % of pre-contracted tone vs. 173.9 ±13.1 % in controls; $p<0.05$, unpaired t-test). There was no significant difference in the response of coronary arteries to SNP between the two groups, indicating that vascular smooth muscle function was unaffected by treatment. Treated sheep also showed significantly reduced circulating levels of the inflammatory marker fibrinogen at days 1,2, 3 and 5 post MPC treatment ($p<0.05$, 2-way ANOVA with Bonferroni post hoc test). This pre-clinical study demonstrated that MPCs given intravenously early in the course of arthritis development are able to attenuate the development of clinical signs, systemic inflammation and endothelial dysfunction in this animal model. The study therefore provides evidence of the efficacy of MPC in modulating the systemic inflammatory effects of collagen-induced arthritis.

TEMOZOLOMIDE POTENTIATES ANTITUMOR EFFECT OF MESENCHYMAL STEM CELLS-BASED TRAIL GENE THERAPY AGAINST MALIGNANT GLIOMA

Seong Muk Kim, Ji Sun Woo, Chang Hyun Jeong, Sin-Soo Jeun
The Catholic University of Korea, Seoul, Korea, Republic of

Because the tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) selectively kills tumor cells, it is one of the most promising candidates for cancer treatment. TRAIL-secreting human mesenchymal stem cells (MSC-TRAIL) provide targeted and prolonged delivery of TRAIL in glioma therapy. However, acquired resistance to TRAIL of glioma cells is a major problem to be overcome. In this study, we showed a potential therapy that used MSC-TRAIL combined with the chemotherapeutic agent temozolomide (TMZ), which is currently used in clinical practice. Treatment of either TRAIL-sensitive or -resistant human glioma cells with TMZ and MSC-TRAIL resulted in a significant enhancement of apoptosis compared with the administration of each agent alone, indicating that TMZ potentiates TRAIL-induced apoptosis. In addition, we demonstrated that TMZ effectively increased the sensitivity to TRAIL-induced apoptosis via the upregulation of the death receptor 5 and the downregulation of antiapoptotic proteins, such as X-linked inhibitor of apoptosis protein and cellular FLICE-inhibitory protein. Subsequently, this combined treatment resulted in a substantial increase in caspase activation. Furthermore, *in vivo* survival experiments and bioluminescence imaging analyses performed in mice bearing intracranial gliomas showed that treatment using MSC-TRAIL combined with TMZ had greater therapeutic efficacy than did single-agent treatments. Overall, these results suggest that the combination of clinically relevant TMZ and MSC-delivered TRAIL is a potential therapeutic strategy for improving the treatment of malignant gliomas.

IMPROVED THERAPEUTIC POTENTIAL OF MESENCHYMAL STEM CELLS VIA MRNA TRANSFECTION

Oren Levy[1], Weian Zhao[1], Luke J. Mortensen[2], Sarah LeBlanc[1], Kyle Tsang[1], Moyu Fu[1], Vinay Sagar[1], Peter Eimon[3], Matthew Angel[3], Charles P. Lin[2], Mehmet Fatih Yanik[3], Jeffrey M. Karp[1]
[1]Division of Biomedical Engineering, Department of Medicine, Center for Regenerative Therapeutics, Harvard Medical School, Harvard Stem Cell Institute, Brigham and Women's hospital, Cambridge, MA, United States, [2]Wellman Center for Photomedicine and Center for Systems Biology, Massachusetts General Hospital, Boston, MA, United States, [3]Department of Electrical Engineering and Computer Science, Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA, United States

Cell therapy possesses tremendous potential for treating a wide array of tragic diseases. Specifically, mesenchymal stem cells (MSCs) are considered candidates for cell-based therapy due to their immunomodulatory and pro-angiogenic secretome and low immunogenicity. However, a major challenge in cell therapy, and especially MSC therapy, is poor cell homing to disease sites following systemic administration. In this study, we used mRNA transfection as an approach to engineer MSC homing and immunomodulatory properties to better control their fate following transplantation. Since cell rolling is considered a key step in the process of cell homing, mRNA transfection was used to induce expression of key rolling ligands on the MSC surface, resulting in a robust rolling response on P-selectin-coated surfaces *in-vitro* as well as on inflamed endothelium *in-vivo*. Moreover, the engineered MSCs exhibited significantly increased homing to sites of inflammation following systemic administration in murine *in-vivo* models. We then generated MSCs that express a functional rolling machinery and a potent anti-inflammatory cytokine. Systemic infusion of MSCs equipped with both homing ligands and an enhanced immunomodulatory secretome showed the greatest local anti-inflammatory effect *in-vivo*. Overall, this study utilizes mRNA transfection to implement a combined approach - enhancing MSC homing as well as augmenting its secretome – to improve MSC therapeutic potential.

TRANSPLANTATION OF HYALURONIC ACID COATED WHARTON'S JELLY MESENCHYMAL STEM CELLS CAN REPAIR LIVER FIBROSIS

Chang-Chun Hsiao[1], Fang-Cheng Huang[2], Te-Yao Hsu[3], TSUNG-CHIH HSIEH[2], HSIN-I CHEN[1]

[1]Graduate Institute of Clinical Medical Sciences, Chang Gung University, Kaohsiung, Taiwan, [2]Department of Chemical and Materials Engineering, Cheng Shiu University, Kaohsiung, Taiwan, [3]Department of Obstetrics, Chang Gung Memorial Hospital-Kaohsiung Medical Center, Kaohsiung, Taiwan

Liver fibrosis (LF) is mainly due to viral hepatitis, autoimmune diseases, alcoholism or chemical drug-induced liver damage caused by a long time. Mesenchymal stem cells (MSC) with immunosuppressive and anti-inflammatory functions, the use of MSC to treat LF are a very feasible. Using of hyaluronic acid (HA)-coated Wharton's jelly MSC (WJMSC) can reduce WJMSC apoptosis and increase proliferation of WJMSC. We use carbon tetrachloride to establish stable and reliable animal model of LF. We use HA-coated 6×10^6 WJMSC transplanted into the liver capsule of LF mice (HA-coated WJMSC treated mice). After 28 days of treatment, type I collagen expression in the liver tissue of HA-coated WJMSC treated mice recovery to same level as normal mice, there is no biological marker of activation of hepatic stellate cells α-SMA expression. Albumin in liver tissue of HA-coated WJMSC treated mice increased significantly to about that 1.9 ± 0.1 fold ($p < 0.01$) of the normal mouse liver tissue. Transplantation HA-coated WJMSC reduced LF mice GOT, GPT, and liver fibrosis area. After 28 days of treatment, in HA-coated WJMSC treated mice liver tissue, there are still a lot of WJMSC and MMP9 expression is very large. MMP9 has been reported in the literature can degrade collagen fibers. Both IL-6 and TGF-β expression in the liver tissue of HA-coated WJMSC treated mice are significantly decreased ($p < 0.05$) compared to those of LF mice and restored to those of normal mice. Therefore, transplantation of HA-coated WJMSC is indeed effective in treatment of LF mice to liver function recovery and reduce the degree of liver fibrosis.

Mesenchymal stem cells (MSC) are reported to have a potent immunosuppressive capacity that prevents tissue damage and increases regenerative potential after injury, a property that has been touted as beneficial in a variety of diseases. Even though the swine model has been used in pre-clinical studies to evaluate the safety and efficacy of MSC therapy, the immunomodulating properties of swine-derived MSCs has not been completely defined. Contradictory results have been reported by several research groups using porcine MSCs from different strains. Strain-specific differences in MSC immunomodulating properties may account for these discrepancies and could have implications for translational studies. Objective: The goal of this study is to compare immunomodulatory activity of human MSCs to two different strains of swine MSCs (Yucatan and Yorkshire) under control and cytokine activated conditions in vitro. Methods: MSCs were isolated from 9 healthy humans, 6 Yucatan and 5 Yorkshire pigs. MSCs were stimulated with interferon-γ (IFN-γ) for 24 h and the levels of major histocompatibility complex class II (MHC-II) expression and anti-inflammatory cytokines: interleukin 10 (IL-10), and transforming growth factor beta (TGFβ) evaluated by flow cytometry and ELISA, respectively. Inhibition of phytohemagglutinin (PHA)-induced T-cell proliferative responses were also quantified using MSC co-cultures. Results: No baseline differences were observed in MHC-II expression between human (0.06%) and porcine (Yucatan=1.1 %; Yorkshire= 0.4%) untreated MSCs. However, IFN-γ treatment induced a significant increase in MHC-II expression in porcine MSCs when compared to baseline and this increase was significantly higher in Yorkshire compared to Yucatan MSCs (Yorkshire:32.6% vs. Yucatan 8.38%,P=0.03). Human MSCs released significantly higher levels of TGFβ(1.7-fold, p=0.01) after IFN-γ treatment that was not observed in porcine MSCs (Yucatan 0.97 fold, Yorkshire 0.77 fold), indicating that human MSCs may

have greater immunomodulatory activities since TGFβ has potent anti-proliferative and anti-inflammatory activities. In fact, allogeneic human MSCs significantly suppressed T cell proliferation in a dose-dependent manner. This effect was independent of MSC direct contact with T-cells, since T-cell proliferation was also suppressed in a transwell assay. In contrast, pig MSCs (Yorkshire or Yucatan) were not able to suppress T-lymphocyte proliferation in vitro. Conclusion: In conclusion, this study demonstrates that regulation of MHC-II differs by porcine strain after IFN-y stimulation, and that at least two commonly used pig strains differ from human in their immunomodulatory response. These in vitro immunomodulatory differences between human and pig MSCs raise the question of pig as a predictive animal model especially in immune-mediated diseases, suggesting direct in vivo comparisons are necessary.

Although many studies show the possibility of stem cell therapy for the regeneration of myocardial infarction (MI), the poor viability and the functional disruption of stem cells in pathologic conditions critically have an influence on the efficacy of stem cell-based therapy. Synovial fluid-derived mesenchymal stem cells (SF-MSCs) are one of the newly reported mesenchymal stem cells and it is expected to be a promising new source of stem cell-based therapy. MicroRNAs (miRs) are short non-coding RNA and play important roles in various biological functions including differentiation, proliferation, and apoptosis by negatively regulating post-translation. In particular, miR-21 has been reported that the effects on cell survival and angiogenesis. In this study, we transfected hsa-miR-21 mimic into human SF-MSCs. Overexpression of miR-21 increased cell survival and angiogenesis-related factors such as phosphorylated AKT and VEGF by targeting phosphatase and tensin homolog (PTEN). We found that luciferase activity and protein expression were diminished in miR-21-transfected SF-MSCs by using luciferase reporter construct containing the 3' UTR of PTEN, as a possible target of miR-21. Using rat MI model, we detected the improvement of cardiac function in miR-21-transfected SF-MSC transplanted group *in vivo*. Our results suggest that miR-21 targeting PTEN contributes to the regeneration of injured heart by transplantation of SF-MSC.

Although mesenchymal stem cells (MSCs) are suitable source for regenerative therapy, the poor survival of MSCs under harsh condition limits the efficacy of cell therapy. MicroRNAs (miRNAs), short non-coding 18~25 nucleotide RNAs, regulate various pathophysiological functions by negatively regulating gene expression. However, the exact mechanism that specific miRNAs could regulate cell survival is still not fully understood. Here, we founded that programmed cell death 6 (PDCD6) and death-associated protein kinase 1 (DAPk1), i.e. pro-apoptotic proteins, are specific targets of miR-124 in hypoxic rat MSCs. We validated the suppression of PDCD6 and DAPk1 in miR-124-transfected cells. Overexpression of miR-124 increased MSC survival in hypoxic condition and specifically regulated the apoptosis and survival-related proteins including phosphorylated-Akt and -ERK1/2, Bcl-2, Bax, cytochrome c, and caspase-3. In addition, annexin V and PI-stained cells were decreased in miR-124-up-regulated group. MSC survival in hypoxic condition was enhanced in miR-124-treated group compared to PDCD6- or DAPk1-siRNA-treated group, respectively. These results represent that miR-124 simultaneously targets PDCD6 and DAPk1 for enhancement of survival in hypoxic MSCs.

Stroke is one of the major causes of death and disability. It is mainly caused by the blockade of blood flow, leading to the ischemic condition that causes irreversible damages to the brain. Despite numerous efforts, therapeutic options for the stroke-damaged patients are still very limited. In this study, we evaluated the therapeutic potential of adipose-derived mesenchymal stem cells (ADSC) to treat stroke using a rodent model of middle cerebral artery occlusion. ADSC are known to secrete many useful cytokines or growth factors, such as BDNF, VEGF, GDNF, HGF, which will facilitate the protection and recovery of stroke-damaged tissues (MCAo). For the delivery route of stem cells, we chose intra-arterial infusion method, since it results in the higher cell counts at the target site, compared with intravenous infusion method. However, since this method can also create the potential risk of embolization of the injected vessels, etc., we carefully monitored the progression of transplantation effects or the occurrence of post-operational side effects. ADSC were infused through internal carotid artery at 24hr after the induction of MCAo, and the transplanted animals were monitored up to 8 weeks. Interestingly, we observed that the transplanted animals exhibited significant improvement in motor and somatosensory functions, judged by rotarod and mNSS (modified neurological severity score) tests, respectively. 4.7T animal MRI analysis indicated that Feridex-labeled ADSC were mainly detected in the infarct area, implying the tropism of infused stem cells. Unlike the previous reports, we were able to detect considerable numbers of transplanted ADSC even 8 weeks after infusion. Immunohistochemical analyses revealed that small portions of transplanted ADSC were differentiated into both NeuN- or MAP2-positive neuronal or GFAP-positive glial lineages. Interestingly, some of the transplanted cells were also differentiated into laminin- or vWF-positive endothelial cell lineages, suggesting that the transplanted ADSC might be also involved in angiogenesis. We also observed that the transplanted animals exhibited increased neurogenesis (higher BrdU and DCX expression), and reduced inflammation (lower Iba-1 and ED1 expression) and glial scar formation (lower GFAP expression). Taken together, these results indicate that, although ADSC cannot give rise to dramatic functional recovery and neuronal regeneration *per se*, wide spectrum of paracrine effects of ADSC can improve the host environment by modulation of neurogenesis, angiogenesis, inflammation, gliosis, etc. It is likely that these unique features of ADSC will collectively contribute to functional improvement in stroke.

This study was supported by a grant of the Korea Healthcare technology R&D project, Ministry for Health,Welfare & Family Affairs (A111016). We are grateful to the MRI facility in the Division of Magnetic Resonance, Korea Basic Science Institute, Ochang, Korea

Abstract

A number of studies have demonstrated the tropism of mesenchymal stem cells (MSCs) in malignant gliomas, making these cells a potential vehicle for delivery of therapeutic gene to disseminated glioma cells. The synovial fluid-derived MSCs (SFMSCs) from osteoarthritis patients are attractive resource for potential clinical application. In this study, we compared the tumor-tropic migratory capacities of various MSCs such as bone marrow-derived MSCs (BMMSCs), adipose tissue-derived MSCs (ADMSCs), and SFMSCs. We confirmed the migratory capacity of MSCs toward tumor cells by an *in vitro* migration and by *in vivo* injection of NIR-675-labeled MSCs into the tumor mass of established human luc-U87-glioma in nude mice. Also, we examined whether soluble factors released by glioma cells could change migration and adhesion related factors and microRNAs (miR) of MSCs. All the MSCs showed a significantly increase migratory capacity toward glioma *in vitro* and *in vivo*. Moreover, SFMSCs showed enhanced the migration capacity toward glioma compared to ADMSCs. Also MSCs treated of conditioned medium increased expression of CD44 and CD49a, which lead to the change of the CD44 targeted- miR-33a-3p and CD49a targeted-miR-124a-5p on MSCs. These results suggest that SFMSCs may have potential use as effective delivery vehicles for therapeutic genes in the treatment of glioma.

CHARACTERIZATION OF THE DYNAMIC MOLECULAR CHANGES IN STEM CELL CHEMOATTRACTANTS FOLLOWING PULSE FOCUSED ULTRASOUND (PFUS) SONICATIONS IN MUSCLE: IMPLICATIONS FOR CELL THERAPY

Pamela A. Tebebi[1], Scott R. Burks[2], Ben A. Nguyen[2], Saejeong J. Kim[2], Ali Ziadloo[2], Priyanka Venketesh[2], L. Christine Turtzo[2], Victor Frenkel[1], Joseph A. Frank[2]

Introduction: Pulsed focused ultrasound (pFUS) has been used as a noninvasive nondestructive technique to enhance tissue permeability and retention in targeted drug delivery. We previously reported elevations in cytokines, chemokines and trophic factors (CCTF) associated with minimal inflammatory changes in the targeted muscle following pFUS, and that pre-treating skeletal muscle or kidney tissue with pFUS induces an enhanced homing, permeability, and retention (EHPR) effect for intravenously-injected mesenchymal stem cells (MSC) in skeletal muscle and kidney tissue. The goal of the present study was to characterize changes in these factors over time in the murine muscle in response to pFUS. Results may point to important signaling pathways that drive the molecular changes following pFUS and reveal an optimum time to administer cells to maximize the EHPR effect and ultimately translate into improved cellular therapies.

Methods: Hamstrings of C3H mice were sonicated using a Sonoblate 500 system at 1 MHz. Sonications were done at 40 W (5% duty cycle, 1 Hz pulse frequency). 100 pulses per site were given in a 2 × 3 matrix (spacing = 2 mm). Treated hamstrings were harvested at various times up to 48 hr post treatment with sham-treated mice representing controls. Tissue homogenates were analyzed by ELISA for levels of CCTF's, and cell adhesion molecules (CAM) at each time point (n=6 per time point). 1×106 human MSC were injected intravenously within 2 hr following pFUS treatment. For ibuprofen experiments, mice were given 30 mg/kg ibuprofen by mouth 15 min prior to pFUS.
Results & Discussion: A biphasic response to pFUS occurs as an initial increase in CCTF (30min-2hr) followed by a second peak of chemoattractive factors at 16 hr that decays through 48hrs. The overall trend was consistent with previously published studies where the early elevation of chemoattactants (i.e., IL17, IL12, M-CSF, VEGF) following pFUS likely drives the expression of other CCTF detected at later time points. Accompanying increased expression of soluble factors was an upregulation CAMs. When MSC are injected <4 hr post-pFUS, homing to the treated region was greatest. However, when injections were performed at 8 hr or 16 hr post-pFUS the magnitude of cell homing was reduced. Additionally, when mice are given ibuprofen prior to pFUS and cell injections, MSC homing to treated tissue does not occur.
Conclusions: The major finding is that the initial mechanical perturbation of the muscle by pFUS results in dynamic molecular biological effects that have important implications on the ability to maximize the EHPR effect for cell therapies. The timecourse of CCTF changes after pFUS indicate that the predominantly mechanical (i.e. non-thermal) effects, through mechanotransduction, give rise into an initial molecular biological response that is responsible for the second peak that occurs at the later time points. While this cascade of molecular changes can capitalized upon to increase homing of MSC, the administration of ibuprofen, a non-steroidal anti-inflammatory drug, blocks homing to pFUS-treated tissue. This suggests that pFUS effects that lead to MSC homing could be mediated by cyclooxygenase (COX) activity. Understanding and exploiting CCTF changes following pFUS provide a mechanism to appropriately time infusion of cell products, screen drug effects on cell homing, and improve delivery of cell therapies for diseases and regenerative medicine.

CELL THERAPY WITH MESENCHYMAL STEM CELLS IN RENAL DAMAGE INDUCED BY IONIZING RADIATION IN AN ANIMAL MODEL.

Vitoria M. Longo, Helena R.C. Segreto, Waldemar S. Almeida, Nestor Schor
Nephrology Division-Medicine Dept, Escola Paulista de Medicina/UNIFESP, Sao Paulo, Brazil

INTRODUCTION AND AIMS: Ionizing radiation (IR) causes cells death depending on the total irradiated dose and upon biological factors in the specific organ. The IR on the kidney's tissue induces time-depending systemic effects (hypertension, proteinuria, anemia, platelet aggregation, and others) as well as renal alterations (reduction glomerular function and diffuse sclerosis etc.). The reparative therapy with mesenchymal stem cells (MSCs) potentially can minimize renal injury alterations induced by IR. AIM: To evaluate the effect of therapy with MSCs in the renal lesions induced by IR. METHODS: MSCs were obtained from male Wistar rats and characterized by FACS. We formed four groups of 9 animals each: control (CTL); vehicle (V); ionizing radiation (IR) in the right kidney, with a dose of 8Gy and, group treated with IR and cell therapy (1X106cells, IR+MSCs). The rats were placed in metabolic cages for analysis of creatinine (CreatS, mg/dL), creatinine clearance (Clcreat, ml/min) and proteinuria (mg/24h) in the 20th and 40th days post-IR. We used immunofluorescence for Y chromosomal location and immunohistochemistry (IHC) for marking inflammation and fibrosis, in both periods.
RESULTS: In day 20 when comparing groups IR and CTL, we found increase in mean Creat (0.96±0.19 vs. 0.34±0.02) and reduction in Clcreat (0.36±0.14 vs. 1.19±0.08), $p<0.05$. Unlike occurred in relation to the IR group alone, animals that received MSCs (group IR+MSCs) presented lower CreatS (0.96±0.19 vs. 0.42±0.04) and higher Clcreat (0.36±0.14 vs. 0.79±0.12), $p<0.05$. In 40th day, the IR group showed an additional aggravation on renal function with significant increase in proteinuria when compared to the CTL and IR+MSCs (31.3±5.07 vs. 10.8±0.08 and 13.4±1.69; $p<0.05$), indicating that the renal function loss process is continuous and could blocked by MSCs transplantation. At 40th day of the evaluation there was a progressive impairments in the levels of CreatS (1.36±0.04 vs. 0.41±0.04 and 0.39±0.03) and Clcreat (0.47±0.08 vs. 1.01±0.13 and 1.06±0.20) in IR group, when compared to

IR+MSCs and CTL; p<0.05, indicating that the protective effects of MSCs, in this model, had a long term efficiency. Elevated levels of inflammatory marker for IL-2 and IL-6 were found in IR but blunted with MSCs treatment. The Y chromosome was persistent in IR+MSCs, indicating a continuous process of reparation.
CONCLUSIONS: Maintenance in Creats and Clcreat levels given by MSCs, in both periods were achieve. The Clcreat and proteinuria are normal after the 40th day in the RI+MSCs. The MSCs prevented the aggressive effect on renal function at 20 days post-IR, and attained normalcy after the 40th day. IHC showed that the presence of a chronic inflammatory process participate, as expected, in the development of this disease. The markup for IL-6 was absent in group IR+MSCs vs. IR, suggesting that MSCs prevented the aggressive effect of acute inflammation. The presence maintained of Y chromosome in IR+MSCs indicated persistence of the harmful inflammatory process despite no more IR aggression. Finally, the data showed that treatment with MSCs induced beneficial effects on the renal damage provoked by IR, and the MSCs transplantation induced beneficial effects in this experimental model.

EFFECTS OF MESENCHYMAL STEM CELLS OR THEIR CONDITIONED MEDIUM IN UNILATERAL URETERAL OBSTRUCTION IN RATS

Andrei Furlan da Silva, Vicente Paulo Teixeira, Nestor Schor
Nephrology Division-Medicine Dept, Escola Paulista de Medicina/UNIFESP, Sao Paulo, Brazil

Introduction and objectives: A substantial knowledge has been accumulated in relation to therapeutic potential of mesenchymal stem cells (MSCs) and its conditioned medium (CM). It is known their ability to repair tissue and reduce local inflammation. A renal tubule interstitial inflammation is one of the principal causes that induce chronic damage, resulting in fibrosis. A model well established for fibrosis is unilateral ureteral obstruction (UUO). In this study we evaluated the effects of MSCs or CM administrations in UUO model. Methods and results: MSCs extracted from rat's bone marrow were cultivated in vitro and characterized by flow cytometry and cellular differentiation. Four groups of female rats were employed in vivo (n=7): SHAM; UUO; UUO+ MSCs and UUO+CM. The MSCs or its CM were administered via cava vein after total left ureter ligation. After 7 days, the rats were sacrificed and serum and UUO kidney were collected. The fibrosis was assessed by deposition of collagen type I and III displayed on staining Picro Sirius Red. Results: We observed a significant improvement in reduction of the fibrosis progression in animals treated with MSCs or CM (UUO 1.2±0.2; MSC 0.3±0.1; CM 0.4±0.1, % of staining area, p<0.05). The expression of molecules related to progression of fibrosis, inflammation and Epithelial-Mesenchymal Transition were evaluated by real time PCR. It was observed reduction in molecules expression such as COL-1(UUO 4.5±0.5; MSC 2.3±0.3; MC 1±0.2, arbitraries unities), α-SMA (UUO 5.2±0.5; MSC 3±0.5; MC 2.7±0.3, arbitraries unities) and TNF-α (UUO 7.7±1.3; MSC 2.0±0.3; MC 1.7±0.1, arbitraries unities) in animals treated with MSCs or MC, p<0.05. In immunohistochemical assays they were observed reductions of 1,5 % in staining area of capase-3 and α-SMA (UUO 7.2±1; MSC 1.0±0.2; CM 0.7±0.1, % of staining area, p<0.05) in treated animals. We also observed a reduction in cell proliferation after MSCs or MC (UUO 3.1±0.7; MSC 0.4±0.1; CM 0.6±0.3, % of staining area, p<0.05). Conclusion: Results suggested that the IV administration of MSCs or its CM minimize the fibrosis progression and change factors involved in apoptosis, inflammation, cell proliferation and Epithelial-Mesenchymal Transition in Wistar rats, subjected to unilateral ureteral obstruction.

Introduction and objectives: There is currently no therapy capable of improving neurological functions in paraplegic patients with chronic complete spinal cord injury (SCI). The administration of bone marrow mesenchymal stem cells (MSC) is a potential therapy for different diseases, including those affecting the spinal cord. Here we evaluated the feasibility, safety and potential efficacy of the transplantation of autologous MSC transplantation in patients with chronic complete SCI. Methods and results: This is an open label phase I/II study, non-controlled, which included 14 patients, aged between 18-65 years, with chronic traumatic SCI (> 6 months before the beginning of the trial), classified as ASIA A, without complete anatomical section of the spinal cord, at thoracic or lumbar segments. All of the patients selected for this trial had previously undergone spinal cord decompression and stabilization. Baseline somatosensory evoked potentials (SSEP), magnetic resonance imaging (MRI) of the spine, and urodynamic study were assessed before isolation of MSCs, and in different time points during a minimum 6-months follow-up. Bone marrow was aspirated from the anterior and posterior iliac crests and MSCs were isolated and cultured in a cGMP facility for approximately 4 weeks, until adequate numbers for transplantation were achieved. Before transplantation, the cells were characterized by flow cytometry analysis, differentiation assays, and G-band karyotyping. Patients underwent laminectomy and durotomy, when the cells were injected directly into the injured area of the spinal cord, in cardinal points. A fixed number of cells per volume of lesion (5x106 cells/cm3) was injected, as determined by MRI analysis. No adverse events of the technique were observed, except for one patient who underwent a second surgical procedure due to a liquoric fistula. The evaluation of clinical parameters showed improvements related to sphincter control and sensitivity in lower limbs. None of the patients evolved with worsening of the urinary function and two patients evolved with normalization of the maximum cystometric bladder capacity. Ten patients had improvement of tactile sensitivity and six patients had motor improvement, as quantified by the ASIA score. Fifty percent of the patients evolved with improved ASIA grades to B or C. One patient presented SSEP potential three months after cell transplantation. Conclusions: Transplantation of autologous BMMC into the lesion of patients with spinal cord injury is safe and feasible. Our results also indicate some benefits of the technique, which should be confirmed in further studies.

EARLY MARKERS OF CELLULAR SENESCENCE IN BONE MARROW-DERIVED MESENCHYMAL PROGENITOR CELLS

Maria da Graca Cabreira, Micheline M. Resende, Xiaohong Wang, Guilherme V. Silva, Daniel Garcia, Doris A. Taylor, Emerson C. Perin
Stem Cell Center, Texas Heart Institute, Houston, TX, United States

Cellular senescence, an innate part of the organismal aging process, can also be induced by insults generated from diseases. Studies have shown that senescent cells disable the proliferation machinery but remain metabolically active and, if not cleared by the immune system, may pose risks for tumor development. We hypothesized that patients suffering from heart failure, a chronic cardiovascular disease, that might inflict systemic cell damage, could be affected by an increase in cellular senescence.
We collected tissue discard from anonymous heart failure patients undergoing bone marrow aspiration (IRB HSC-MS-09-0527, University of Texas Committee for the Protection of Human Subjects; N=4) for the isolation of mesenchymal/stromal progenitor cells (MPC). Control MPC were isolated from healthy marrows (N=4) purchased from Lonza, Inc. Cells were expanded in growth medium containing 10% fetal bovine serum at 500/cm2 plating density in 5 and 20% O2 tension. Cell characteristics were fully quantified by immunophenotype, clonogenic activity, analysis of growth kinetics and differentiation potential. Transcriptome analysis by microarray was performed on control MPC grown in 5% and 20%. The abundance of 86 senescence-associated transcripts in control and patient cell cultures was compared by PCR array (SABiosciences). Analyses were performed on cells at log phase in the third passage. In terms of cell characteristics, we found no differences between control and patient samples. We found

that MSC from patients when grown at 5% O2 expressed significantly lower levels of Chek1 (2.8 fold; p= 0.007), Id1 (3.5 fold; p=0.01) and PCNA (2.5 fold; p=0.01). We compared expression profiles of cultures expanded in 5% O2 tension to samples in 20% so we could also evaluate whether or not the changes on the senescence profile could be attributed to possible stress caused by culture conditions. 5% O2 tension proved to be the most adequate for the analysis because the results were in agreement with in vivo and in vitro published data. In addition, higher than control protein expression levels of p16, an important senescence marker not included in the array, was detected in patient MPC grown under 5% O2 tension by Western blotting, in agreement with the decreased levels of Id1.
Our screening for senescence markers was performed at early population doublings, when cells retained a relatively robust proliferation capacity because our goal was to obtain a consistent pre-replicative senescence gene expression profile or signature from cultured cells that represents the intrinsic aging occurring in the patient sample that could also reveal pathophysiological processes involved in it. These findings are very preliminary and will need to be validated in larger cardiovascular patient population. We are presently investigating the involvement of Smurf2 on ID1 ubiquitination and upregulation of p16 in patients' samples.

THE SCTIVATION OF DIRECTIONAL STEM CELL MOTILITY BY GREEN LIGHT-EMITTING DIODE IRRADIATION

Oscar Lee[1], **Jennifer Ho**[2]
[1]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan, [2]Center for Stem Cell Research, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan

Light emitting diode (LED) irradiation is potentially a photostimulator to manipulate cell behavior by opsin-triggered phototransduction and thermal energy supply in living cells. Directional stem cell motility is critical for the efficiency and specificity of stem cells in tissue repair. We explored that green LED (530 nm) irradiation directed the human orbital fat stem cells (OFSCs) to migrate away from the LED light source through activation of extracellular signal-regulated kinases (ERK)/MAP kinase/p38 signaling pathway. ERK inhibitor selectively abrogated light-driven OFSC migration. Phosphorylation of these kinases as well as green LED irradiation-induced cell migration was facilitated by increasing adenosine triphosphate (ATP) production in OFSCs after green LED exposure, and which was thermal stress-independent mechanism. OFSCs, which are multi-potent mesenchymal stem cells isolated from human orbital fat tissue, constitutionally express three opsins, i.e. retinal pigment epithelium-derived rhodopsin homolog (RRH), encephalopsin (OPN3) and short-wave-sensitive opsin 1 (OPN1SW). However, only two non-visual opsins, i.e. RRH and OPN3, served as photoreceptors response to green LED irradiation-induced OFSC migration. In conclusion, stem cells are sensitive to green LED irradiation-induced directional cell migration through activation of ERK signaling pathway via a wavelength-dependent phototransduction.

CHARACTERIZING THE IMMUNOSUPPRESSIVE ACTIVITY OF HUMAN MULTIPOTENT STROMAL CELLS USING A MOUSE MODEL OF AUTOIMMUNE DISEASE

Cristina Nazarov, Jessica LoSurdo, Steven Bauer, Cheng-Hong Wei
CBER, FDA, Bethesda, MD, United States

Multipotent stromal cells (MSCs) are known to have immunosuppressive activity. They are postulated to evade allospecific T cell responses, making them promising tools for reducing the severity of graft vs. host disease and other autoimmune diseases. Although the immunosuppressive effect has been extensively studied *in vitro*, the molecular mechanisms *in vivo* remain elusive.

In our *in vivo* model, we first activate $CD8^+$ T cells specific for a pancreatic islet antigen, then we inject them (i.v.) in NOD/Scid mice to induce type 1 diabetes (T1D). One day prior to the $CD8^+$ T cell transfer, we infuse the NOD/Scid mice with human MSCs (hMSCs) (i.p.) and monitor blood glucose levels every 3 days.

In this study we show that we were able to induce T1D within 3 weeks after injection of antigen-specific autoreactive $CD8^+$ T cells into NOD/Scid mice. Injection of hMSCs prior to the $CD8^+$ T cells delayed the onset of disease by approximately 2 months when compared with mice not injected with hMSCs. A second injection of $CD8^+$ T cells in euglycemic, hMSCs treated mice resulted in rapid disease progression, suggesting that the hMSCs only temporarily retained in NOD/Scid mice. Injection of hMSCs after the $CD8^+$ T cells did not protect mice from developing the disease, suggesting a role for the microenvironment in priming the hMSCs for immunosuppression. Moreover, the immunosuppressive effects seem to be specific to MSCs; transfer of human fibroblasts instead of hMSCs showed no protection from T1D in our model.
Further studies are underway to investigate the mechanisms underlying the immunosuppressive function of hMSCs *in vivo* and to distinguish between the immunosuppressive capacities of hMSCs from different donors and culture passages.

HOMING OF TOPICALLY APPLIED MESENCHYMAL STEM CELLS TO THE BRAIN PARENCHYMA IN AN EXPERIMENTAL TRAUMATIC BRAIN INJURY MODEL

PK Lam[1], Anthony WI Ip[2], Kevin KW Wang[4], Henry CH Lau[1], Kevin KC Leung[3], Kathy TC Li[3], Paul BS Lai[3], WS Poon[3]
[A]Dept of Surgery, Chow Tai Fook-Cheng Yu Tung Surgical Stem Cell Research Center, [B]Dept of Anatomical & Cellular Pathology, [C]Dept of Surgery, [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Center of Neuroproteomic & Biomarkers, University of Floria, Florida, FL, United States

Mesenchymal stem cells (MSCs) have the capabilities of neuroprotection and promoting functional recovery in traumatic brain injury (TBI). To maximize the biologic effects, MSCs should be delivered to the target region. In most clinical settings, MSCs are commonly transplanted by systemic infusion. Due to the blood-brain barrier and pulmonary trapping, engraftment rate of the infused MSC into the brain parenchyma is very low. Direct implantation of MSCs into the brain through Hamilton syringe is risky. In this study, we investigated whether the topically applied MSCs could migrate to the injured site in a rodent model of TBI. MSCs derived from the adipose tissue of transgenic green fluorescent protein (GFP)-Spague-Dawley (SD)rats were applied to the external surface of left parietal cerebral cortex of wild-type SD rats (N=10) 2 days after TBI which was induced by a controlled cortical impact (CCI) at the contralateral side. The MSCs were held in position by a thin layer of fibrin glue. Immunohistochemistry staining of GFP showed that 5 days after topical application, the MSCs migrated along the corpus callosum and reached the TBI site on the contralateral cerebral hemisphere. On the other hand, the topically applied MSCs proliferated superficially on the cortex at the application site in the sham-injured control animals without TBI (N=8). No GFP-MSCs were found in the other somatic organs in the test and control animals. Our experiment demonstrated that topical application provides a direct delivery of MSCs to the target organ and the microenviroment of TBI can facilitate the migration of MSCs from the external surface of cerebral cortex to the injury site of the brain.

CULTURE OF UROTHELIUM AND MESENCHYMAL STEM CELLS FROM HUMAN URINARY TISSUES

Joelson Tomedi[1], Annelise R. Rosa[2], **Patricia Pranke**[3], Ilma S. Brum[4], Brasil S. Neto[5], Milton Berger[5], Nádya P. Silveira[6]
[1]Post-graduate Program in Material Science; Post-graduate Program in Physiology - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [2]Post-graduate Program in Material Science; Hematology and Stem Cell Laboratory, Faculty of Pharmacy - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [3]Post-graduate Program in Material Science; Post-graduate Program in Physiology; Hematology and Stem Cell Laboratory, Faculty of Pharmacy - Federal University of Rio Grande do Sul; Stem Cell Research Institute, Porto Alegre, Brazil, [4]Post-graduate Program in Physiology - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [5]Department of Surgery, Uro-

logy Division - Hospital de Clínicas, Porto Alegre, Brazil, [6]Post-graduate Program in Material Science; Chemistry Institute - Federal University of Rio Grande do Sul, Porto Alegre, Brazil

Since the first reports on successful engineered urothelial tissue implants at the end of the 20th century, there has been an increasing interest in using reconstructive therapy in patients who suffer irreversible damage to urinary tissues. An effective approach in urologic tissue engineering involves isolation and culture of urothelium and smooth muscle cells for further combination in scaffolds. Although smooth muscle cells have demonstrated the capacity to generate a functional stroma, there has been a growing interest in using mesenchymal stem cells for this purpose. Current thinking is that they can solve the problem of harvesting cells from the donor site, especially when it is severely damaged. This study reports on an approach to isolate urothelium and mesenchymal stem cells from urinary tissues. In addition, the preliminary results of their interaction to temporary matrices prepared with natural biopolymers are presented.
Segments of ureter obtained from nephrectomies provided urothelial cells. At the same time, adipose-derived stem cells (ADSCs) were harvested from a small amount of periureteral and perirenal fat and expanded with Dulbecco´s modified Eagle´s medium (DMEM) supplemented with 10% fetal bovine serum (FBS). A sample of ADSCs was separated in order to perform immunophenotypic characterization and differentiation assay. Following this, each cell type was seeded on scaffolds produced with a combination of gelatin, hyaluronic acid and heparin. The cells and scaffolds were incubated for 2 weeks in DMEM containing 5% FBS. After this period, matrices were fixed in 4% paraformaldehyde and stained with hematoxylin and eosin (HE).
Both cellular types were expanded in primary cultures. Flow cytometry analysis evidenced that ADSCs derived from urinary tissues exhibited a positive expression of CD29 and CD90, and a negative for CD34, CD45 and HLA-DR. Moreover, their adipogenic and osteogenic differentiation potentials were demonstrated in vitro. HE stained paraffin sections of scaffolds showed that urothelial cells were able to form a single layer. On the other hand, ADSCs cultured on temporary matrices developed a multilayer arrangement.
This study reports that human urothelial cells and mesenchymal stem cells can be isolated from urinary tissues in a single procedure. ADSCs obtained from urinary tissues possess immunophenotypic characteristics and differentiation potential similar to those derived from peripheral fat. It was also observed that both cellular types were able to attach and grow in the scaffolds produced. Further studies will evaluate if it is feasible to generate a urothelial mucosa combining both cellular types.

HYPOXIA PRECONDITIONING CULTURE ENHANCES BONE MARROW-DERIVED MESENCHYMAL STROMAL CELLS MIGRATION AND PARACRINE EFFECTS BY TROPHIC FACTORS.

Min Young Noh, Young Seo Kim, Kyung Ah Cho, Won Jun Choi, Seong-Ho Koh, Seung Hyun Kim
Neurology, Hanyang University College of Medicine, Seoul, Korea, Republic of

Bone marrow-derived Mesenchymal stromal cells (MSC) are emerging candidate cells for the treatment of neurological diseases. However, the majority of MSCs transplanted by hypoxic environment fail to reach the site of injury, and they have demonstrated only minimal therapeutic benefit in clinical trials. Therefore, oxygen tension plays a pivotal role in the migration of MSC. In this study, we aimed to determine whether hypoxia preconditioning could increase the migration capacity of MSCs during *ex vivo* expansion. In MSC cultured at oxygen as low as 1%, rates for cell death and hypoxia-induced gene transcription remained unchanged, while cell migration was significantly increased, western blot analysis revealed increased levels of migration-related signaling proteins such as CXC chemokine receptor 4 (CXCR4). In addition, overexpression of prosurvival genes like Akt can reduced hypoxia-induced cell death, decresed in cell senescence, and exhibit enhanced trilineage differentiation. Hypoxia preconditioning also modulates the paracrine activity of MSCs, causing upregulation of various secretable factors, among which are important angiogenic factors such as vascular endothelial growth factor (VEGF), basic fibroblast growth factor-2 (bFGF-2), and angiogenin (ANG). These findings suggest that Hypoxia preconditioning during *ex vivo* expansion of hBM-MSCs may provide a general method of enhancing their engraftment in vivo into a variety of tissues.

REDUCTION IN PERICAPSULAR FIBROSIS BY CO-ENCAPSULATION WITH MESENCHYMAL STEM CELLS

Bernard E. Tuch, Vijayaganapathy Vaithilingam, Gail A. McFarland, Penelope A. Bean, Margaret DM Evans
Materials Science & Engineering, CSIRO, North Ryde, Sydney, Australia

Pericapsular fibrotic overgrowth (PFO) needs to be overcome for cellular therapies involving encapsulation in an immunoprotective material to be clinically successful, for example, in the treatment of diabetes. Mesenchymal stem cells (MSC) have innate anti-inflammatory properties and we postulated that co-encapsulation of these with the target cells would reduce PFO. We tested this hypothesis using the human HUH7 cells and co-encapsulated them with either human or mouse MSC in alginate using an air droplet generator to produce microcapsules. Microcapsules were delivered into a xenogeneic model using immunocompetent C57BL6 mice either intraperitoneally (ip) or subcutaneously (sc) and maintained for 21 days. Control groups included empty alginate microcapsules, and microcapsules containing HUH7 cells alone or MSC cells alone. A previously published fibrotic scoring system was used to quantify the degree of PFO following post-mortem retrieval of microcapsules from all test groups.
Data from retrieved intraperitoneal microcapsules showed that PFO for HUH7 cells co-encapsulated with human and mouse MSC in a ratio of 1:1 reduced the fibrotic score by 30% and 35% respectively compared with HUH7 cells alone. Increasing the ratios of mouse MSC:HUH7 to 2:1 and 3:1 further reduced the fibrotic score by 52% and 48% respectively compared with HUH7 alone. When microcapsules were implanted sc rather than ip, PFO for HUH7 cells co-encapsulated with mouse MSC in a ratio of 2:1 was reduced by 54% compared with HUH7cells alone. Taken together, these outcomes showed that the best outcome was achieved when MSC were co-encapsulated with HUH7 in a ratio of 2:1 and implanted sc. However, this outcome did not take into account the formation of a fibrotic pouch around the sc implanted microcapsules although the viability of cells in microcapsules retrieved after 21 days was 90%.
In summary, PFO was reduced to in a challenging mouse model with an active immune system by co-encapsulating mouse MSC with the target cells in a ratio of 2:1 with further benefit obtained by implanting them sc rather than ip.

Pre-clinical and Clinical Applications of Mesenchymal

W-3043

AN IMMUNOTHERAPY STUDY TO COMPARE IMMUNOMUDULATORY OF MESENCHYMAL CELLS DERIVED FROM BONE MARROW AND ADIPOSE TISSUES FOR APPLICATION IN NON-HUMAN PRIMATE KIDNEY TRANPLANTATION

fattah sotoodehnejadnematalahi, Nasser Aghdami, Hossain Baharvand
Royan institute, Tehran, Iran, Islamic Republic of

Multipotent non-hematopoietic progenitor mesenchymal stem cells are originally isolated from bone marrow (BM) as well as adipose tissues and they are capable of differentiating into various mesodermal lineages. Several studies have reported low immunogenicity for MSCs as they appear to have great potential to be used as modulators of immune responses in a variety of diseases related to alloreactive immunity in addition to organ transplantation. In vitro studies have shown immunosuppressive effect of MSCs on T cells, B cells and natural killer cells as well as in vivo prolong skin graft survival. Studies have proposed human adipose tissues (hAD) as an unlimited source of MSCs which showed to have very similar immunological properties to MSCs derived from hBM. As MSCs isolation from BM knows as an aggressive method, therefore in this project we aim to isolate MSCs from adipose tissues and then study in vivo immunomodulatory effect of hAD-MSCs on immune responses in kidney xenograft. In addition, we aim to compare the immune regulation of hAD-MSCs in kidney transplantation in nonhuman primates with hBM-MSCs and identify any possible immunomodulative differences between hAD-MSCs and hBM-MSCs. Understanding of immune modulation consequences by hMSCs is required for their use as derivatives of adipose tissues which provide cells for immunotherapy in clinical applications.

W-3044

MIR-141-3P ACCELERATES HUMAN MESENCHYMAL STEM CELL AGING BY DIRECTLY TARGETING ZMPSTE24

Kyung-Rok Yu
Seoul National Univ, Seoul, Korea, Republic of

ZMPSTE24 is involved in the post-translational maturation step of lamin A. Defects in ZMPSTE24 are associated with the accumulation of prelamin A in the nuclear envelope and lead to premature senescence. However, the signaling pathways that modulate ZMSPTE24 expression levels during adult stem cell senescence have not been elucidated. We found that human mesenchymal stem cells (hMSCs) down-regulated ZMPSTE24 and accumulated prelamin A during replicative or HDAC

inhibitor-induced senescence. The miR-141-3p, which is over-expressed during the senescence process, was able to decrease the ZMPSTE24 expression levels and led to an up-regulation of prelamin A and a DNA damage marker in hMSCs. The transfection of anti-miR-141-3p prevented the reduction of ZMPSTE24 in VPA/SB-treated cells, resulting in the suppression of the induction of abnormal nuclear morphology. In addition, epigenetic histone markers of the chromatin configuration on the miR-141-3p promoter region were transcriptionally activated during senescence. Our findings demonstrate a crucial role of ZMPSTE24 in hMSC senescence.

HETEROGENEITY OF SKELETAL PROGENITORS IN MOUSE BONE MARROW.

Maria Rostovskaya, Konstantinos Anastassiadis
Biotec, Dresden, Germany

Bone marrow stroma contains a complex of mesenchymal progenitors generating cells of skeletal tissues, such as osteocytes, chondrocytes and adipocytes. The studies of skeletal progenitors in vivo are hampered by the lack of specific surface markers for their identification in the tissue. On the other hand, a limited proliferative capacity represents a major limitation for the in vitro characterization of those cells.
We generated transgenic mice carrying a modified tetracycline-inducible system for the expression of simian virus 40 (SV40) Large T-antigen depending on the presence of two ligands, Dexamethasone and Doxycycline. Bone marrow mesenchymal stromal cells (BM MSCs) were isolated from the transgenic mice and expanded upon induction of Large T expression.
Conditionally immortalized BM MSCs maintained the capacity to differentiate to osteo-, adipo- and chondrocytes and expressed surface markers characteristic for MSCs. Importantly, the cells did not change those properties after extended passaging. We performed a screening of surface markers of BM MSCs using a panel of 176 antibodies and high-throughput flow cytometry. We found 33 antigens to be expressed, and among them 3 novel for BM MSCs and 13 that have not been reported for MSCs from mice. To our knowledge, this is the most comprehensive characteristic of mouse BM MSC immunophenotype reported to date.
As a next step, we established single-cell derived BM MSC subpopulations by limiting dilutions, and analyzed them for the osteogenic and adipogenic potential. We identified osteogenic, adipogenic and bipotential progenitor types and further checked them for the expression of surface markers by screening with the antibody panel. We found CD200 as a marker of osteogenic lineage and SSEA4 and CD140a as a characteristic of adipogenic cells. Those findings were validated by cellular sorting of BM MSCs followed by the in vitro differentiation.
Furthermore, we characterized transcriptome of tri-, bi- and monopotential BM MSC progenitors using Illumina RNAseq. We identified distinct transcriptional signatures for the osteogenic and adipogenic lineages (all clones that contain “O” or “A” property, respectively), and found that the progenitors with both potentials (“OAC” and “OA”) combine those signatures, and do not express unique genes.
Taken together, we performed an extensive characterization of osteo- and adipogenic lineages in BM MSC progenitors, and identified surface markers and transcription signatures characteristic for these cell types.

THE CLINICAL POTENTIAL OF BONE MARROW MESENCHYMAL STEM CELLS (MSCS) CANNOT BE EXTRAPOLATED TO MSCS ISOLATED FROM THE MENSTRUAL FLUID DUE TO MAJOR DIFFERENCES IN THEIR IMMUNOSUPRESSIVE PROPERTIES

Patricia Luz-Crawford[1], Maria-Jose Torres[1], Ainoa Fernandez[2], francisca Alcayaga-Miranda[1], Lorena Salazar[1], Fernando Figueroa[1], **Maroun Khoury**[1]
[1]Faculty of medicine, Laboratory of miRNA and stem cells, Universidad De Los Andes, Santiago, Chile, [2]Universidad Andres Bello, Santiago, Chile

The harvest of mesenchymal stem cells (MSCs) from adult tissues such as the bone marrow or adipose tissue is possible but requires invasive procedures that include discomfort and sometimes complications. Moreover, to reach

clinically effective dosages these sources require a large-scale expansion that might modify their stem-like properties and hence their therapeutical efficacy. A highly proliferative stem cell was recently identified from menstrual blood. The collection of these cells is non-invasive, free of complications and can be repeated periodically in a simplified and reproducible manner that none of the existing sources can match. However, more research is an imperative to analyze their regenerative and immunomodulatory properties.This study focuses at comparatively characterizing the immunoregulatory properties of menstrual stem cells (MenSCs) as opposed to the presently available MSC sources.
In a proliferation assay, MenSCs exerted a significantly less immunosuppressive effect than bone marrow MSCs (BM-MSCs) when cocultured with allogenic activated PBMCs at a 1:10 ratio, (50% and 70% of T cells proliferation respectively and in comparison with the condition without MSCs). Surprisingly, they showed a stimulatory effect on T cells when diluted to a 1:100 ratio (156% of
T cell proliferation) whereas BM-MSCs maintained their suppressive effect (40%). When looking at the different generated T cell subtypes, a significantly higher number of proinflammatory Th1 (11,6% vs 4,5%) and CD8+INFg+ cells (14,1% vs 6,5%) and lower number of Treg and CD4+IL10+ cells(3,5% vs 7%) was observed at a 1:100 ratio when compared to BM-MSCs. Upon INFg and IL-1B stimulation, they showed less secretion and expression of the immunomodulatory molecules PDL-1, IDO, COX-2 and TGFB1. In addition, they showed a dramatic lower surface expression of the IFN-g receptor subunits as well as lower TLR3 and TLR4 levels. In a Xeno-GVHD model, where NOD-SCID Il2rg(-/-) where injected with total human PBMCs, BM-MSCs alleviated the symptoms of GvHD by the immusupression of T cells populations, in contrast, MenSCs had no therapeutical benefit. In conclusion, we demonstrate that MenSCs do not possess the immunosupressive potential when compared to BM-MSCs due to the low expression level of many factors involved in this mechanism. The need of this type of information is decisive with respect to the development of safe and effective cell therapies for immune mediated diseases as many autologous and allogenic clinical trials using these cells are being planned.

W-3047

PROSPECTIVE ISOLATION AND CHARACTERIZATION OF MULTIPOTENTIAL MESENCHYMAL STROMAL CELLS AND COMMITTED OSTEOPROGENITOR CELLS IN MOUSE BONE MARROW

Ching fang Chang[1], Ke hsun Hsu[1], Jhih jia Liao[2], Chia Yi Yang[2], Chung leung Li[3], Jean Lu[2]
[1]Institute of Microbiology and Immunology, National Yang-Ming University, Taipei city, Taiwan, [A]Stem Cell Program, Institute of Genomics Research Center, [B]Stem Cell Program, Institute of Cellular and Organismic Biology/Genomics Research Center, [2]Academia Sinica, Taipei city, Taiwan

Currently multipotential stromal/mesenchymal stem cells (MSCs) are defined mostly on their in vitro differentiation capacity and cell surface marker profile. However whether these characterization parameters are physiologically relevant remains unclear and should be critically addressed. To further complicate the issue, MSCs are mostly studied as a heterogeneous population of cultured adherent cells and even if the differentiation potential is measured at clonal level, the initiating cells have already undergone a minimum of 20 population doublings, so it is difficult to determine whether the observed multipotential differentiation potential truely reflect that of the original initiating cell or has been acquired during culture expansion. In an attempt to clarify the above issues, we chose to use FACS to isolate different cell populations based on their differential expression of Sca-1, CD24, and PDGFR-α (Pα) antigen within the (CD31/CD45/Ter119)- marrow stromal cell fraction. Based on the results of in vitro differentiation assays performed on the short-term culture expanded cells and primary colony assays performed on fresh isolated cells, the Sca-1hi, Sca-1lo and Sca-1- cell fractions are enriched for MSCs, committed osteoprogenitors and mature ALP+ osteogenic cells respectively and we propose a hierarchical stepwise differentiation model for the osteoblast cell lineage within the marrow. More complete data including (i) in vivo ectopic bone formation and osteogenic reconstitution assays will be presented to further substantiate the proposed model. We believe that this pivot study will provide a strategy and platform to investigate the function and developmental relationship of MSC and the osteoprogenitors in vivo in the near future.

GENE EXPRESSION ANALYSIS OF AGING HUMAN MULTIPOTENT STROMAL CELLS

Ian H. Bellayr[1], Jennifer G. Catalano[1], Samir Lababidi[2], Amy X. Yang[1], Jessica L. LoSurdo[1], Steven R. Bauer[1], Raj K. Puri[1]

[1]CBER, Office of Cellular, Tissue and Gene Therapies, FDA, Bethesda, MD, United States, [2]CBER, Office of Biostatistics and Epidemiology, FDA, Rockville, MD, United States

Stem cell based therapies have tremendous potential in the field of regenerative medicine to treat human disorders, such as organ failure, traumatic limb injuries, and genetic disorders. Multipotent stromal cells (MSCs) isolated from bone marrow can be expanded in vitro and have the potential to differentiate into osteogenic, chondrogenic and adipogenic cell lineages. In addition, as MSCs have inherent characteristics to suppress the immune system, they are also being studied in preventing graft-versus-host disease. However, MSCs have not been fully characterized by unique markers that can define their quality and thus predict their safety and effectiveness. Moreover, the impact of growth characteristics, donor variability, age and the sex of the donors has not been fully realized on the function and identity of these cells. The objective of this study was to identify genes that were associated with aging by cell passage. Human MSCs from 8 different donors, grown under identical culture conditions and harvested at different cell passages (3, 5, and 7), were analyzed by high-throughput microarrays. Total RNA with an average RNA integrity number (RIN) of 9.9 ± 0.16 was isolated from each sample. Microarrays containing 35,000 70-mer oligonucleotide probes were produced in-house at Food and Drug Administration, Center for Biologics Evaluation and Research. Dual dye labeled cDNA was hybridized to the microarray overnight where a common reference RNA composed of equal aliquots of passage 3 RNA from 6 donors was employed. All samples were run in triplicate by a randomized block design. An Analysis of Variance with multiple testing corrections found that 34 probes were statistically significant with 12 of them having an unknown function. The 22 known genes were imported into ingenuity pathway analysis software and analysis of the top scoring networks ($p<0.05$) had the functions of carbohydrate metabolism, small molecule biochemistry and cellular development. Four of the known genes were found to have a statistically significant trend with increasing passage. It is expected that the results obtained from this study will identify molecular markers that improve the ability to predict MSC performance. The identification of such biomarkers will facilitate the clinical development of MSCs in regenerative medicine.

W-3051

THE MRNA STABILIZING PROTEIN, CRD-BP/IMP1 AND TET FAMILY MEMBERS COOPERATE TO REGULATE HUMAN MESENCHYMAL STEM CELL PROLIFERATIVE CAPACITY.

LOUISA MAHAIRA, **OLGA KATSARA**, CONSTANTIN BAXEVANIS, MICHAEL PAPAMICHAIL, SONIA PEREZ
SAINT SAVAS, CANCER IMMUNOLOGY AND IMMUNOTHERAPY CENTER, ATHENS, Greece

Mesenchymal Stem Cells (MSC) is a population that can be found in many tissues and can differentiate towards many different lineages. Unraveling the molecular profile of MSC is of great importance, due to the fact that these cells are very often used in preclinical and clinical studies. We have previously reported the expression of CRD-BP/IMP1- an oncofetal mRNA binding protein- in different stem cell populations, specifically bone marrow (BM)-MSC and umbilical cord blood- hematopoietic stem cells (UCB-HSC), and have attributed to it an important role in stem cells with high self-renewal capacity. Now we demonstrate for the first time that MSC of adipose tissue (AT), BM, and UC origin have a differential pattern of CRD-BP/IMP-1 expression that could correlate with their proliferation rate- since gene knocking down resulted in significant reduction of cell proliferation and self renewal. We also provide evidence for the involvment of TET family members in the epigenetic regulation of CRD-BP/IMP-1 in human MSC; and show that TET1, TET2, CRD-BP/IMP1 along with c-MYC are pivotal parts of a complex network involved in the regulation of MSC proliferative capacity.

W-3052

STEM CELL FROM THE VOMERONASAL ORGAN: POTENTIAL FOR USE IN CELL THERAPY

Marcio N. Rodrigues[1], Rafael C. Carvalho[2], Dayane Alcântara[1], Graciela C. Pignatari[1], Káterin E. B Grondona[3], Maria A. Miglino[1]

[1]Surgery, University of Sao Paulo, Sao Paulo, Brazil, [2]Federal University of Maranhao, Chapadinha, Brazil, [3]Center of Agricultural Science, Federal University of Paraiba, Areia, Brazil

The vomeronasal organ (VNO) is located at the base of the nasal cavity, has a tubular shape, is divided by the nasal septum, and forms part of the olfactory pathway. It emits chemical signals that detect pheromones and modulate social and reproductive behavior. The VNO has stem cells adjacent to the basal lamina, able to divided and migrate to replace sensory neurons, these stem cells can generate functional neurons throughout animal life. The aim of study was to isolate and characterize cells derived from the vomeronasal organ of New Zealand rabbits. Five male rabbits were used for collection of the VNO explants, and three culture media were tested (α-MEM, DMEM-F12, and High-Glucose). Cells were possible to be isolated in all media tested. However there was a greater confluence and cell growth when was used the High-glucose media, confirmed by the proliferation assay (MTT). In immunocytochemistry positive staining was observed for CD105, CD90, CD 73, Nanog, Vimentin, Cytokeratin 18, beta-tubulin, nestin, GFAP, PCNA, Oct-4, and Stro-1, negative reactions was observed for CD45, CD34 and CD117. In flow cytometry, they were negative for CD45 and CD34 and positive for Nanog (34.6%), CD 105 (46.6%), CD 90 (48.4%), Oct ¾ (45.1%) and Stro-1 (48%). Cultured cells were able to functionally differentiate into adipocytes, osteocytes and chondrocytes nor carninoma was formed when performed the assay in nude mice. It was possible to verify that the cells could be isolated in all three protocols proposed and they provide security for cellular therapy, since there was no formation tumorigenic.

W-3053

COMPARATIVE EVALUATION OF OCT-4, SOX2 AND C-MYC EXPRESSIONS IN HUMAN DENTAL PULP STEM CELLS VS. HUMAN DENTAL FOLLICLE STEM CELLS

Razieh Karamzadeh[1], Mohamadreza Baghaban Eslaminejad[1], Reza Aflatoonian[2]

[1]Department of Stem Cell and Developmental Biology at Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Iran, Islamic Republic of, [2]Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, Islamic Republic of

Background:
Induced pluripotent stem cells (iPSCs) technology has been open a promising place in the field of regenerative medicine by providing the transformation of somatic cells into iPSCs with four core transcription factors, Oct-4, Sox2, c-Myc & Klf4. Recently, it has been shown that these transcription factors express in human dental pulp stem cells (hDPSCs), which may involve in maintaining stem cells self-renewal capacity. Lately, there is a subtype of dental stem cells known as dental follicle stem cells (hDFSCs), which shows mesnechymal stem cells (MSCs) features & differentiation potentials into mesodermal and/or non-mesodermal lineages. According to the different types of stem cells in dental tissues & their various differentiation capacities, we investigate the expression patterns of Oct-4, Sox2 & c-Myc in hDPSCs compare to the hDFSCs.
Methods:
hDPSCs & hDFSCs were enzymatically isolated from wisdom teeth (n=3) and characterized in terms of surface epitopes (MSC markers CD90/CD73/CD44/CD105, hematopoietic/endothelial markers CD34/CD45/CD11b/CD31 & Pre-vascular marker CD146) as well as differentiation capacity into bone, cartilage & adipose cells. Then, these two types of cells were undergone to comparative assessment of Oct-4, Sox2 & c-Myc expressions by QPCR & Immunofluorescence.
Results:

hDPSCs & hDFSCs showed MSC phenotype & differentiation capacity into three mesenchyme lineages. Immunophenotyping results confirmed the existence of MSC markers and the lack of hematopoietic/endothelial markers in both groups. The results of QPCR & Immunofluorescence indicated the expressions of Oct-4, Sox2 & c-Myc genes in both hDPSCs & hDFSCs. Interestingly, these results showed significant higher expression of Sox2 & c-Myc genes in hDPSCs in comparison with hDFSCs. In contrast, Oct-4 gene expression was more in hDFSCs compare to the hDPSCs. These results may show distinct role of Oct-4, Sox2 & c-Myc, as the core reprogramming factors, in these cells.

IS SUBSTANCE P A CHEMOTACTIC FACTOR TO ATTRACT STEM CELLS TO THE DYSTROPHIC MUSCLE?

Amanda F. Assoni, Natássia M. Vieira, Mariane Secco, Marcos Valadares, Juliana PA Gomes, Mayra Pelatti, Mayana Zatz
INSTITUTO DE BIOCIENCIAS, UNIVERSIDADE DE SÃO PAULO, São Paulo, Brazil

Progressive Muscular Dystrophies (PMD) are a clinical and genetic heterogeneous group of diseases characterized by a progressive and irreversible degeneration of skeletal muscles with variable distribution and severity. The therapeutic potential of mesenchymal stromal cells (MSCs) from different sources such as bone marrow, umbilical cord tissue, adipose tissue and dental pulp has been thoroughly investigated for PMDs. However, to date, none of the pre-clinical trials involving cell therapy in different animal models for PMDs showed a complete success (restoration of both absent or defective protein and functional recovery). Therefore, enhancement of both cell homing and differentiation will be of great importance in an attempt to obtain a more successful cell therapy for PMDs. Different soluble factors released by cells present at sites of injury may attract and stimulate MSCs population. Recently it was reported that substance P (SP) acts as chemotactic for MSC after injury. SP is a neurotransmitter that is associated with neurokinin-1(NK-1), producing different responses such as vasodilation, plasma protein extravasation in post capillary venules and leukocytes adhesion on endothelial cells of venules. Here we evaluated the expression of SP in the dystrophic muscle of different PMDs murine models (dy2J, SJL, mdx, as compared to C57B6 and Swiss as background controls), quantified its receptor, NK-1, in different sources of MSCs(bone marrow, umbilical cord, adipose tissue, periosteum, palate, dental pulp, menstrual blood, endometrium, fallopian tubes, orbicularis oris muscle, as compared to fibroblasts which were used as controls) and correlated its expression with its potential as a chemotactic factor. Thirty-four (6-7 per group) animals were used for quantification of gene and protein expression of SP. To quantify NK-1, 70 lineages of MSCs (5-7 per group) were analyzed into passage 4.The results demonstrated great variability in the amount of SP in the muscles of the murine models within the lineages . Interestingly a greater amount of SP was observed in muscles from the mdx mice, as compared to normal controls, a finding which is currently being further investigated. Among the different sources of MSCs, wide intra variability in NK-1 amount was also observed. However, stem cells derived from fat showed in general a higher quantity, which may be important for choosing the best source aiming a possible therapy. The experiments to correlate the amount of SP receptor with the chemotactic potential of SP over MSCs are currently underway.

Abstract

BACKGROUND: Tissue specific stem cells have been recently identified in osteoarthritic (OA) cartilage tissues on the basis of their migratory properties. However, the characteristics and biological activities of the Cartilage Stem/Progenitor Cells (CSPC) in OA are not clearly known.

AIM: This study aims to study the phenotype markers of CSPCs during in vitro amplification and analyze their relationship with OA development and therapy.

METHODs: Cartilage biopsy was harvested from human OA and normal knee joints with institutional approval. CSPCs were isolated by clonal selection and expanded in low density culture. Cell phenotype was evaluated with immunofluorescence, flow cytometry, and qRT-PCR. The CSPC subpopulation was selected by FACS. Osteo- and adipogenic differentiation was evaluated by Alizarin Red and Oil-red O staining, respectively, and chondrogenic differentiation was analyzed in pellet cultures.

RESULTS: CSPCs were isolated from 30 OA and 10 normal cartilage samples. A dynamic temporal profile of the phenotype markers, CD146 and collagen type II (Col2), was seen - Col2 was positive after isolation and became negative after passage 3, while CD146 became positive with passage from ~30% in P1 to ~80% in P3. IL-1β treatment increased cell proliferation of normal CSPCs and upregulated endogenous IL-1βexpression, but did not affect the percentage of CD146+ cells. FACS-sorted CD146+ CSPCs showed 2-fold higher clonal forming ability compared to CD146- cells, suggesting that CD146 may be a biomarker for CSPCs. Interestingly, some sorted CD146- cells transitioned into CD146+ cells after monolayer culture. Expression profiles of several genes related to self-renewal and multipotency regulation (actin fliament-associated protein, Frizzled 7, Dickkopf 3, protein tryosine phosphatase receptor F, and RAB3B) also changed with passage, RAB3B was upregulated and the PTPRF/FZD7/DKK3/AFAP was downregulated. Compared to human bone marrow stromal cells (BM-MSCs), CSPCs exhibit multiple linage differentiation ability, but are less osteogenic and adipogenic. After 4 weeks in chondrogenic culture, BM-MSC pellets retained some fibroblast like phenotype in the center, but CSPC pellet consisted largely of cells with chondrocyte like phenotype. The cells in CSPC pellets were Col2+ and CD146-, but became CD 146+ again when they migrated away from the pellets and subsequently cultured in monolayer.

CONCLUSIONS: These findings demonstrated the kinetic and biological profile of the phenotype of CSPCs, and implicated their alterations and possible roles during OA pathogenesis.

ENHANCING EX-VIVO EXPANSION OF CORD BLOOD-DERIVED UNRESTRICTED SOMATIC STEM CELLS FOR CLINICAL APPLICATIONS

Hanan G. El-Baz[1], Zeinab A. Demerdash[1], Faten S. Mahmoud[1], Salwa H. Mohammad[1], Kesmat M. Maher[1], Dina S. Abd El Hady[1], Marwa H. Ahmad[1], Tamer F. Taha[2]

[1]Immuonology Departement, Theodor Bilharz Research Institute, Cairo, Egypt, [2]Reproductive Health Departement, National Research Center, Cairo, Egypt

ABSTRACT

BACKGROUND: Cord blood (CB) derived Unrestricted Somatic Stem Cells (USSCs) hold great promise as therapeutic agents in regenerative medicine and autoimmune diseases. Ex-vivo expansion of USSCs is a prerequisite for evaluating their therapeutic potential in ongoing clinical trials. This study was designed to determine factors (such as: seeding density, culture media and growth supplements) driving USSCs population to expand extensively to generate cell number suitable for clinical application.

STUDY DESIGN AND METHODS: Isolation, propagation and characterization of USSCs from CB samples were performed. The influence of log fold decreased USSCs seeding (5000, 500, 50 and 5 cells /cm2) in three culture me-

dia; 30% FBS/DMEM, 2% FBS/EGM-2, and serum free media (Mesencult), on clinical-scale expansion of USSCs, was evaluated.
RESULTS: USSCs isolated from 9 out of 12 CB samples (75%) showed the classical MSCs morphology of adherent fibroblastoid spindle-shaped cells growing in a monolayer. USSCs expressed high levels of CD44, CD90 CD73 and CD105, whereas they were negative for CD34, CD45, and class II (HLA-DR). They showed high expression of transcripts for Oct4 and Sox2 which are the core transcription factors in early embryo development and pluripotency maintenance in embryonic stem cells. In addition, they were induced to differentiate into osteoblasts and adipocytes. USSCs cultured in 30% FBS/DMEM showed significantly higher Population Doubling (PD) ($p<0.001$) than those cultured in EGM-2 or Mesencult at all cell densities. PD of USSCs cultured at 5 cells /cm2 in either 30% FBS/DMEM, or EGM-2, was significantly higher ($p<0.001$) than those cultured at higher densities. However, at a higher cell density (50 cells /cm2) PD of USSCs cultured in Mesencult was significantly increased ($p<0.001$) than that of other densities.
CONCLUSION: On the basis of optimizing cell culture conditions of USSCs to scale up their number to a high level suitable for clinical applications, the following two step scenario is recommended; Step one: Culturing of CB-derived USSCs of early passages (P1-P3) in 30% FBS/DMEM at low cell seeding density (5 cells /cm2) to allow for scaling up of USSCs count with less passaging frequency, to avoid the unwanted effects of repeated trypsinization. Second step: Culturing of the expanded USSCs (>P3) in Mesencult serum free medium at a higher cell seeding density (50 cells /cm2), to avoid the undesirable effects of FBS on cultured cells. The efficiency of this two-step procedure for clinical-scale USSCs propagation may facilitate rational clinical testing of USSCs-based therapies.

BIOMIMETIC NICHE DESIGN FOR GROWTH FACTOR MEDIATED DIFFERENTIATION OF HUMAN ADIPOSE DERIVED MESENCHYMAL STEM CELLS TO CARDIAC LINEAGE

Subha S
Thrombosis Research Unit, Sree Chitra Tirunal Institute for Medical Sciences and Technology, Thiruvananthapuram, India

Myocardial infarction (MI) is a leading cause of morbidity and mortality worldwide. Regeneration of damaged cardiac tissue involves generation of cardiomyocytes (CMs) and other supporting cells. Out of all cells essential for cardiac regeneration, CM is most important for retaining the contractile and electrical activity of heart muscle. Replication of CM is difficult as they are terminally differentiated cells. Mobilization, homing and differentiation of cardiac stem cell is not achieved due to poor milieu conditions after MI. Cardiomyoplasty using various cell sources including embryonic stem cells, induced pluripotent stem cells and adult stem cells have reported encouraging results but unsatisfactory clinical outcome. Differentiation of stem cells to cardiac lineage may be achieved using culture matrix immobilized with chemokines and cytokines. Polymerized fibrin can retain growth factors to produce bio mimetic culture matrix; however, cell-specific composition may be needed for each cell type. The objective of this study is to constitute a fibrin-based bio mimetic matrix for lineage commitment of adipose derived mesenchymal stem cell (ADMSC) to enable potential use of adipose tissue as autologous source for regenerative therapy in MI patients.
Adipose tissue was collected from human patients during cardiac surgery with institutional ethics committee's approval. Cells released upon collagenase treatment were cultured using standard published protocol. Cells from third passage were characterized using panel of 3 positive (CD105, CD44, CD90) and 2 negative (CD34 and CD45) surface markers. Thin layer of fibrin matrix was prepared by clotting fibrinogen concentrate on thrombin adsorbed surface. The bio mimetic matrix of the niche comprised fibrin, fibronectin, gelatin and growth factors (GFs) such as bone morphogenetic protein-4 (BMP-4) vascular endothelial growth factor (VEGF) and fibroblast growth factor (FGF). Culture- expanded, homogenous ADMSCs were seeded onto the matrix. Low glucose DMEM supplemented with fetal calf serum and GFs was used to grow the cells. Graded concentrations of BMP-4, VEGF and FGF were tried out to identify a composition that produced maximum number of CMs. Nanogram level of GFs per 2 mg fibrino-

gen concentrate constituted a matrix composition which induced morphological changes to ADMSCs, suggesting lineage commitment into CMs. Immunological and genetic markers were used to characterize CM. Cardiac lineage markers Flk1, N-cadherin and c-Kit indicated matrix directed differentiation; percentage of CM was found to be low in flow cytometric analysis. Differentiation of MSCs into cardiac lineage was confirmed by studying the expression levels of cardiac specific transcription factors including Nkx2.5 and GATA-4.
Conclusion: Combination of adhesive matrix proteins and growth factors at a specific composition induced differentiation of ADMSC into cardiac lineage in vitro. More optimization is required to improve the yield of CM precursors for potential application for MI therapy using autologous adipose tissue.

COMPARISON BETWEEN IN VITRO DIFFERENTIATIONS OF ADIPOSE DERIVED MESENCHYMAL STROMAL CELLS FROM TWO DIFFERENT SOURCES: OUTER THIGH AND ABDOMEN

Juliana P. Gomes, Natássia M. Vieira, Marcos C. Valadares, Amanda F. Assoni, Mayra Pelatti, Mariane Secco, Mayana Zatz
University of São Paulo, São Paulo, Brazil

We have previously observed that adipose (ADMSC) and umbilical cord derived mesenchymal stromal cells have different behavior when injected in a dystrophic mouse model, which could be explained by the intimacy between the cells and their niche - or microenvironment. On the other hand, we and others have found that adipose tissue is a rich source of MSCs. Therefore, the aim of the present study was to verify if ADMSC from different niches differ in their in vitro potential to differentiate in specific cell lines or maintenance of stem cell multipotency. In order to circumvent individual variability we have obtained two ADMSC paired samples from nine unrelated donors: right or left outer thigh and abdomen. These samples were analyzed for their in vitro chondrogenic, adipogenic, myogenic and osteogenic differentiation potentials, during a 21 day differentiation protocol. Specific commercial inducing medium (Invitrogen) was used and the induced samples were compared with their negative control, which was cultivated with non-inductive medium DMEM Low Glucose. Myogenic differentiation was evaluated on days 0, 8 and 15 of differentiation by Real Time PCR of dystrophin and myosin encoding genes expression and also by Western Blot and immunohistochemistry. For adipogenic differentiation both quantitative (AdipoRed) and qualitative (Oil Red) colorimetric test were applied on day 21. Chondrogenic differentiation was analyzed by Toluidine Blue staining. Osteogenic potential was evaluated by alkaline phosphatase activity on day 10 of differentiation and by Alizarin Red staining on days 14 and 21. The Alizarin Red staining was extracted from the plate with an alcoholic solution and was quantitatively measured in a spectrophotometer. No differences were observed for myogenic, adipogenic or chondrogenic differentiation between ADMSC from the two sources. However, Alizarin Red staining on day 21 revealed a statistically significant difference for osteogenic differentiation in samples obtained from thighs as compared to abdomen (Mann-Whitney test; $P < 0.05$). These observations suggest that ADMSC from outer thigh have a better osteogenic potential than ADMSC from abdomen. Aiming to validate these results, studies by Real Time PCR for expression of genes related with osteogenic in vitro differentiation as well as in vivo experiments are in progress.

EVALUATING THE EFFICACY OF ENDOTHELIAL CELLS DIFFERENTIATED FROM ADIPOSE DERIVED MESENCHYMAL STEM CELLS FOR IN VITRO INTIMA CONSTRUCTION

A. Eser ELCIN[1], Y. Emre ARSLAN[2], Y. Murat ELCIN[2]
[1]Ankara University Stem Cell Institute & Faculty of Science, TEBNL; Gazi University GEF, Ankara, Turkey, [2]Ankara University Stem Cell Institute & Faculty of Science, TEBNL, Ankara, Turkey

Adipose tissue is an attractive candidate to become a major stem cell source for regenerative medicine and tissue engineering applications. Adipose-derived mesenchymal stem cells (AdMSCs) possess multilineage differentiation potential. Differentiation into mesodermal cell types, i.e. into adipocytes, chondrocytes, osteoblasts, and myo-

cytes has been shown in several studies. They also can be induced to differentiate into ecto and endodermal origin, e.g. hepatocytes, pancreatic islet cells, neural cells, epithelial cells, and endothelial cells (ECs). The objective of this study was to investigate the differentiation capacity of human (h) AdMSCs into vascular endothelial-like cells, and to evaluate the efficiency of their use for in vitro construction of a functional tunica intima layer into an engineered-vascular scaffold. Methods. hAdMSCs were isolated from human lipoaspirates, expanded, then immunophenotypically characterized by FACS and by their tri-lineage differentiation potential. Passages 4-6 were used in all experiments. AdMSCs were seeded on collagen type IV-coated surfaces and cultured for 7 and 14 days in the EC-GM containing FGF2, VEGF, heparin, IGF-I, EGF, hydrocortisone, and ascorbic acid. hAdMSCs were also seeded inside a nanofibrous tubular polymer scaffold and differentiated into ECs either in static or flow conditions. As positive control, human internal mammary artery endothelial cells (hIMAECs) were isolated and expanded on bovine skin gelatin-coated tissue culture plates in EC proliferative medium (EC-PM); hAdMSCs cultured in standard medium without differentiation inducers served as the negative control in all experiments. To evaluate EC characteristics, immunohistochemistry studies were performed using antibodies against six EC-specific proteins. Additionally, acetylated-low density lipoprotein (ac-LDL) uptake and expression of endothelial cell nitric oxide synthase (eNOS) were determinated for endothelial cell function analysis. Results: Human AdMSCs had CD 90+, CD105+, CD73+, CD29+, CD44+, CD34-, CD45-, and CD133- immunophenotype and demonstrated tri-lineage differentiation potential. Immunohistochemistry demonstrated that hAdMSCs on nanofibrous tubular construct differentiated into endothelial-like cells, and expressed CD31 (PECAM-1), CD34, von Willebrand factor (vWF), VE- cadherin (CD144), tie-2 and flk-1 (VEGFR2) at day 7. Overall, the expression levels of these endothelial specific proteins significantly increased after 14 days which were comparable with that of the hIMAECs. While the expressions of eNOS and ac-LDL uptake were found to be quite low in static culture, a positive influence was observed under in vitro biomimetic shear conditions. Conclusion. Human adipose mesenchymal stem cells can be differentiated into functional vascular endothelial-like cells inside a nanofibrous tubular scaffold under flow conditions that express EC-specific proteins. Findings support the notion that the tunica intima can be constructed in vitro using ECs derived from hAdMSCs. Currently, we are testing the possibility of increasing expression levels of eNOS and ac-LDL uptake by constructing a media layer containing smooth muscle cells in close contact with the neointima layer inside a a real time computer-controlled bioreactor system.

TRANSPLANTATION OF ADIPOSE TISSUE DERIVED MULTI LINEAGE PROGENITOR CELLS VIA PORTAL VEIN IMPROVED SERUM LEVELS OF BETA GALACTOSIDASE IN GM1 GANGLIOSIDOSIS MODEL MICE.

Mayumi Soeda[1], **Hanayuki Okura**[1], Junichiro Matsuda[2], Minako Koura[2], Mitsuko Morita[1], Junko Tani[1], Akihiro Ichinose[3], Akifumi Matsuyama[1]

[1]Foundation for Biomedical Res & Innovation, Kobe, Japan, [2]Laboratory of Animal Models for Human Diseases, National Institute of Biomedical Innovation, Osaka, Japan, [3]Kobe University Hospital, Kobe, Japan

Background: GM1 gangliosidosis and Morquio B are autosomal recessive storage disorders caused by the deficiency of β-galactosidase (GLB1). We have reported that adipose tissue-derived multi-lineage progenitor cells (ADMPCs) could reprogrammed into hepatocyte-like cells in situ and the cells have improved the serum cholesterol levels of familial hypercholesterolemia model Watanabe heritable hyperlipidemic rabbit. Here we examined whether ADMPCs could ameliorate the GLB1 levels of GM1-gangliosidosis model GLB1-knockout mice. Methods and Results: GLB1 expressions of ADMPCs were examined by mannose-6-phospahte (M6P) and mannosamine competition release into cultured media. Incubation with them revealed GLB1 secretion into cultured media in dose dependent manner, resulted in ADMPCs express GLB1. Next, GLB1-knockout mice were received normal mice-derived ADMPCs (n=6) or lactic control (n=3), via portal vein and followed for 4 weeks, and then the serum levels of GLB1were examined by beta-galactosidase enzymatic activities. The serum levels of GLB1 were 7.1 mU of beta-galactosidase (normal control mice, n=6), 0.46 (GLB1-knockout mice treated with lactic control, n=3) and 3.54 (GLB1-knockout mice treated with ADMPC, n=6), respectively. There results indicated the ADMPCs transplantation could improve GLB1 deficiency in GM1-gangliosidosis model mice. To confirm in situ survival of the ADMPCs in hepatic milieu,

GFP-mice-derived ADMPCs (GFP-ADMPCs) were transplanted via portal vein and their liver specimens were applied for histological analysis 4 weeks later. As reported ADMPCs were survived in hepatic milieu and reprogrammed into albumin-expressing hepatocyte-like cells. Conclusion: These results indicated that the transplantation of ADMPC via portal vein is a potentially effective therapeutic strategy for GM1-gangliosidosis.

NEW DEFINED CELL CULTURE CONDITIONS IN COMBINATION WITH A 3D-SCAFFOLD FOR ASCS BONE TISSUE ENGINEERING

Mattia Corazza[1], Greta Minonzio[1], Luca Mariotta[1], Mauro Gola[2], Gianni Soldati[1]
[1]Swiss Stem Cell Foundation, Lugano, Switzerland, [2]Stem Cell Research, Lugano, Switzerland

Introduction. Skeletal tissue loss due to congenital defects, disease or injury is normally treated by autologous tissue grafting. This method is limited by the low availability of host tissue, harvesting difficulties, donor site morbidity and clinician's ability to manipulate delicate 3D shapes.
The generation of autologous bone grafts in vitro is the ultimate goal in bone tissue engineering because it avoids the harvesting of autologous tissue from a second anatomic location. To achieve this, three major components have to be developed and optimized: I) cell culturing in a defined medium, II) the osteoinductive cocktail and III) the scaffold.
Results. We developed a protocol for the extraction and culturing of Adipose tissue-derived multipotent Stromal Cells (ASCs) which fulfils the strict European regulations concerning the Advanced Therapy Medicinal Products. ASCs were grown inside a 3D-scaffold (Osteoxenon) developed by BIOACTIVA S.r.l (Italy). This scaffold is based on decellularized equine bone grafts. ASCs were obtained from liposuction aspirates, cultured and expanded using a protocol developed in our laboratory. After seeding the ASCs into the scaffold, the cells were cultured for three weeks in the presence of our new defined xeno-free osteogenic induction medium.
After fixation of the cells with standard techniques, the scaffolds were sliced and stained. The sections were examined by electron microscopy in order to evaluate the cell morphology, spreading and adhesion properties. The ability of the cells to properly differentiate was explored using standard techniques (histology and PCR) on early or late osteogenic markers like RunX2, SPP1, TW1.
Conclusions. Here we show that the scaffold "Osteoxenon", in combination with our defined culture conditions, is suitable for the growth and differentiation of ASCs into osteogenic cells. Furthermore, the bone tissue engineering strategy described here appears to be very promising for the development of protocols for the treatment of bone loss and injury. In the future, the performance of our in vitro generated autologous bone graft will be studied in a human clinical study.

PURIFICATION AND DIFFERENTIATION OF HUMAN ADIPOSE DERIVED STEM CELLS THROUGH SILK SCREEN/PLGA HYBRID MEMBRANES BY MEMBRANE FILTRATION METHOD

Li-Yu Chen, Yi-Wei Huang, Meng-Hsueh Wu, Chia-Ju Hsu, Chia-Yi Lin, Akon Higuchi
Department of chemical and Materials Engineering, National Central University, Jhongli City, Taiwan

Human adipose-derived stem cells (hADSC) represent one of the most promising cell candidates in the field of regenerative medicine, it can easily be extracted in large amount compared to bone marrow stem cells and also exhibited a higher proliferation rate in the medium. Furthermore, hADSCs also have a great differentiation capability into mesoderm (muscle, bone, and cartilage) and ectoderm (nerves and epidermal). The cultivation of adipose tissue cells contains adipose stem cells with several other types of cells, so it is necessary to purify hADSCs before using them for clinical applications. Purifying hADSCs via the culture process requires 5-12 days by using the conventional culture method. We developed a membrane filtration method to purify hADSCs using novel membranes where the operation time is less than 30 min to purify hADSCs from adipose tissue solution in this study. We prepared silk screen/PLGA hybrid membranes (scaffolds) by a freeze drying method where silk screens (170 mesh size)

are natural and readily biodegradable protein fibers to be used reinforcement of the membranes and PLGA has biodegradability and biocompatibility to be used to generate a sponge pore morphology of the membranes. The average pore size of the silk screen/PLGA hybrid membranes was measured to be 3.5-7µm from scanning electron microscopy. After the preparation of home-made silk screen/PLGA hybrid membranes, we investigated the purification of hADSCs from adipose tissue solution (adipose tissue-derived stromal vascular fraction [SVF]) having different cell density by the membrane filtration method and compared the purification efficiency of hADSCs. The mesenchymal stem cell (MSC) markers such as CD44, CD73, and CD90 expressed by hADSCs were less than 10% in the adipose tissue solution (SVF), while the MSC markers in the permeate solution were found to be 30-50%, indicating hADSCs were concentrated after permeation through the silk screen/PLGA hybrid membranes, when 9 ml of the adipose tissue solution having 1x106 cells/ml was permeated through the membranes. The MSC markers of the cells after 12 days of culture of the adipose tissue solution (hADSCs purified by the conventional culture method) were found to be 60-80%. The efficiency of hADSC purification in the permeate through the silk screen/PLGA hybrid membranes analyzed by MSC markers depended on the cell density of the adipose tissue solution. Currently 1x106 cells/ml was the optimal cell density compared to 2x106 cells/ml or 4x106 cells/ml when 9 ml of adipose tissue solution was used. It was demonstrated that more than two fold higher osteogenic gene expression, Alizarin red staining, and von Kossa staining was observed in the permeate solution compared to the adipose tissue solution (SVF) when the cells were cultured in osteogenic induction medium for 28 days. Therefore, the hADSCs were purified in the permeation solution demonstrated a superior capacity for osteogenic differentiation than the cells in the adipose tissue solution (SVF). The polyurethane foaming membranes having pore size of 11 µm could not purify hADSCs in the permeate solution. This result indicates that the pore size and membrane material are important factors to purify the hADSCs by the membrane filtration method. It is concluded that the hADSCs can be easily isolated through the permeation through the silk screen/PLGA hybrid membrane, whereas non-hADSCs are blocked by the sieving effect of the membrane pore size and/or adhered on the membrane.

W-3065

MAPK ACTIVITY MAY MEDIATE THE DEGREE OF ADIPOSE-DERIVED STEM CELL OSTEOGENESIS

Patricia Zuk[1], Eric J. Tsang[2], Benjamin Wu[3]
[A]Surgery, [B]Biomedical Engineering, [C]Department of Biomedical Engineering, [1]University of California, Los Angeles, CA, United States

Numerous studies have identified a critical role for MAPK signaling in mediating osteogenic differentiation. To assess this signaling cascade's role in Adipose-derived Stem Cell (ASC) osteogenesis, MAPK signaling was functionally assessed in multiple ASC populations induced toward the osteogenic lineage using several inductive conditions. Increased ASC mineralization with respect to non-induced controls was measured upon induction with ascorbic acid and β-glycerophosphate alone, with levels increasing further by adding dexamethasone or 1,25-dihydroxyvitamin D3 (VD3). While heterogeneity in ASC mineralization was found, mineralization capacity appeared to correlate to kinase activity. Specifically, increased mineralization upon induction with dexamethasone (Dex) coincided with significant increases in ERK1/2 or JNK1/2 activation (i.e. pERK, pJNK) with respect to controls. A synergistic effect was noted as ASCs with the highest mineralization capacities also showed increases in both pERK and pJNK. No discernible relationship between mineralization and kinase activation was observed using hydrocortisone rather then Dex. However, VD3 induction gave similar results to Dex, suggesting that these osteogenic agents may act through downstream MAPK pathways. Consistent with this, increased mineralization levels could be induced using recombinant wild-type lentiviruses designed to overexpress either ERK1 or ERK2 (i.e. ERK1wt, ERK2wt). In contrast, ASC mineralization capacity could be inhibited using pharmacologic inhibitors to MAPK kinase activation. Inhibitor administration at the start of osteogenic differentiation significantly inhibited AP activity and mineralization, suggesting a role for MAPK activity in ASC osteogenic commitment. Mineralization capacity was also decreased using these inhibitors prior to the onset of mineralization or throughout osteogenesis, suggesting additional roles for MAPK signaling in ASC osteogenesis. Transduction of osteo-induced ASCs with ERK1/2 or JNK1/2 shRNA lentiviruses also decreased mineralization. In support of a role for MAPK signaling in ASC osteogenesis, enhanced mineralization capacity and increased kinase activation were also associated with decreased MAPK phosphatase expression. Inhibition of phos-

phatase activity not only reduced kinase activation to basal levels but significantly reduced mineralization capacity. Finally, the effects of MAPK signaling on ASC osteogenesis was assessed in vitro using populations transduced with ERK1wt and ERk2wt lentiviruses and implanted into critical-sized parietal defects in athymic rats. In summary, the results indicate that the degree of ASC osteogenesis may be related to the level of ERK and JNK activation and may involve a complex interplay between kinase and phosphatase activity.

ISOLATION AND CHARACTERIZATION OF MESENCHYMAL STEM CELLS FROM BOVINE AMNIOTIC FLUID AT DIFFERENT GESTATIONAL AGES

Barbara Rossi[1], Barbara Merlo[1], Eleonora Iacono[1], Pier Luigi Tazzari[2], Francesca Ricci[2], Cesare Galli[3]
[1]Department of Veterinary Medical Sciences, University of Bologna, Ozzano Emila (BO), Italy, [2]Service of Transfusion Medicine, S.Orsola-Malpighi Hospital, Bologna, Italy, [3]Avantea, Laboratory of Reprodutive Technologies, Cremona, Italy

Introduction - Amniotic fluid (AF) is a reservoir of multipotent mesenchymal stem cells (MSCs), very promising cells for tissue engineering in clinical application. The aim of this work was to isolate and characterize bovine MSCs from AF (bAF-MSCs) as alternative sources of primitive multipotent stem cells in a species that could be an attractive large-animal model for biomedical and biotechnology researches. Materials and Methods - Samples were recovered, at slaughterhouse, from 18 pregnant cows at different gestational ages established on crown-rump length (1: 0-105 d; 2: 106-160 d; 3: 161-200 d; 4: 201-240 d; 5: 241 d-term of pregnancy). Cells were isolated by centrifugation and cultured in DMEM-TCM 199 (1:1) plus 10% FBS. At passage (P) 4, chondrogenic, osteogenic and adipogenic differentiation were induced (n=16) and evaluated morphologically and cytologically (Alcian Blue, Von Kossa and Oil Red O stainings respectively). Phenotypic characterization for stem cell markers was performed at P3 or P4 by flow cytometry for CD105, CD90, CD45 and CD14 (n=16), by immunocytochemistry (ICC) for Oct4, SSEA1, SSEA4 and α-SMA (n=4) and by RT-PCR analysis for Oct4, Nanog and Sox2 (n=7). In both ICC and RT-PCR, bovine fibroblasts were used as negative control. Results - Mean collected AF volume was 35 ml and 200-3636 cells/ml were recovered. Cells were isolated from 16/18 samples. At P0, cell populations appeared heterogeneous and we could identify 4 different cell types: round, spindle-shaped, fibroblastoid and large-flat cells. These different populations were observed at every gestational age analyzed. Through passages, only round cells (n=15/16) predominated. In only one sample, spindle-shaped cells prevailed. After 30 d of culture mean cell doublings were 14,1±3,2 and mean doubling time was 57,7±27,9 hrs without differences related to gestational age or sample ($p>0.05$). Cells were able to differentiate into osteocytes and adipocytes; chondrogenesis was clearly obtained only from samples recovered within 140 d of pregnancy (n=9). Percentage of cells positive for CD90 was 73,0±17,2, for CD105 45,8±35,7, for CD14 5,6±11,2 and for CD45 13,4±11,3; no differences were observed among different gestational ages ($p>0,05$). ICC demonstrated low presence of SSEA4 positive cells (0,05%) in 1 sample, the presence of α-SMA in all 4 samples (mean 11,8±14.1%, range 2.5-32.4%) and the lack of Oct4 and SSEA1. RT-PCR analysis, performed at P4, showed expression of Nanog in 1/7 sample and weak expression in 4/7 samples. Low expression of SOX2 was detected in 2/7 samples. Conclusions - Based on these preliminary results, in the bovine AF there is an heterogeneous cell population containing also multipotent

MSCs, identified by their differentiation ability and phenotypic characteristics typical of MSCs. Unlike human AF-MSCs, only a fraction of bAF-MSCs are positive for some pluripotency markers. Current work is ongoing to further characterize other cell phenotypes selected after long term culture.

QUANTIFICATION OF CARTILAGE-SPECIFIC GENE EXPRESSION IN CHONDROGENIC CULTURES OF HUMAN AMNIOTIC FLUID AND MARROW MSCS IN COMPARISON WITH CHONDROCYTES PRESENTED IN HYALINE CARTILAGE

Fatemeh Safari[1], Mohamad reza Baghaban Eslaminejad[2]

[1]*Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Iran, Islamic Republic of,* [2]*Department of Stem Cells and Developmental Biology, Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Iran, Islamic Republic of*

Introduction: While **c**artilage diseases result in chronic pain and decreased quality of life, cartilage tissue possess a limited capacity to heal. Cell therapy approaches using bone marrow-derived mesenchymal stem cells (MSCs) represent a novel strategy in dealing with treatment of cartilage diseases. Unfortunately, bone marrow tissue as a source of MSCs exhibits some drawbacks due to its invasive and painful obtaining procedure. To address this problem, scientists have long been searching for providing an alternative source, which contains MSCs population. Amniotic fluid, as one of the readily available sources, has drawn many attentions. In the present study, MSCs were isolated from human amniotic fluid and their level of in vitro chondrogenic differentiation were compared to that of marrow-derived MSCs using quantification of expression of some cartilage-specific genes. In this study, differentiation level of both cells was compared to that of native chondrocyte presented at hyaline cartilage tissue.
Methods: Amniotic fluid was collected from patients undergoing cesarean and transferred to the cell culture Lab where the fluid was centrifuged and the cell pellet was plated under standard condition. Bone marrow was obtained from patients who were volunteer for cell therapy at Royan institute. Mononuclear cells were enriched via density gradient centrifugation and then cultured. Passaged-3 cells from both tissues were pelleted under 300g and treated with standard chondrogenic medium for a period of 3 weeks. Normal human hyaline cartilage was obtained from the patients who had car accident and referred to hospital. Cartilage produced from stem cell differentiation as well as the normal cartilage tissue were histologically prepared for toluidine blue staining. Furthermore, total RNA was collected from the chondrogenic cultures as well as the normal hyaline cartilage and quantitative PCR was performed for the cartilage specific genes.
Results: According to our observation, chondrogenic culture from amniotic fluid stained more intensive than that from marrow MSCs. The amount of metachromatic matrix produced at either culture tended to be significantly lower than that exist at normal hyaline cartilage. According to our findings, amniotic fluid stem cells appeared to express cartilage specific genes including *SOX9, COLLAGEN II, AGGRECAN* and *PERLECAN* at expression levels significantly more than their marrow counterparts ($p<0.05$). Although the expression level of amniotic fluid stem cells tended to be lower than that in normal chondrocytes, but they relatively showed more similarity to normal cartilage tissue than marrow MSCs.
Conclusions: Taken together, chondrocytes produced from chondrogenic differentiation of either amniotic fluid stem cells or marrow MSCs possess significantly less cartilage-specific gene expression level compared with those of normal chondrocytes present at hyaline cartilage. In this regards, amniotic fluid-derived chondrocyte is more similar to native cells; hence preferred cells for cell-based treatment of cartilage defects.

W-3068

PLURIPOTENCY AND DIFFERENTIATION OF STEM CELLS CULTURED ON BIOMATERIALS GRAFTED WITH EXTRACELLULAR MATRIX HAVING DIFFERENT ELASTICITY

Chia-Ju Hsu, Yi-Wei Huang, Li-Yu Chen, Pin-yu Wang, Akon Higuchi

Department of chemical and Materials Engineering, National Central University, Jhongli City, Taiwan

Mesenchymal stem cells (MSCs) are a valuable cell source for tissue engineering and regenerative medicine. Stem cells derived from amniotic fluid (AFSCs) are pluripotent fetal cells capable of differentiating into multiple lineages, containing representatives of all the three embryonic germ layers. AFSCs are categorized as the intermediate stage between the embryonic stem cells (ESCs) and adult stem cells, and AFSCs may have a distinct mechanism to choose their fate. Therefore, amniotic fluid represents a rich and more suitable source of stem cells in regenerative medicine and tissue engineering than ESCs and induced pluripotent stem cells (iPSCs) due to the lack of ethical concerns regarding use of ESCs and the lack of concerns about xenogenic contamination arising from the use of mouse embryonic fibroblasts as a feeder layer for iPSCs and ESCs. However, stem cells fate of decision is regulated not only by stem cells themselves, but also the effect of microenvironment of stem cells. Therefore, stem cell microenvironment surrounding specific matrix proteins should be important to decide the stem cell fate of differentiation. The optimal design of stem cell culture biomaterials will facilitate the in-vitro production of the large numbers of pluripotent stem cells and specifically more numbers of differentiated cells, which are demanded in the regenerative medicine. In this study, we investigated whether the stiffness of cell adhesion substrates affect the maintenance of pluripotency of the stem cells and/or modulated the stem cell fate of differentiation. Stem cells from amniotic fluid were cultured on different stiffness of polyvinylalcohol-co-itaconic acid (PVA-IA) films grafted with extracellular matrix (ECM) dishes where collagen, fibronectin, and vitronectin were selected for further studies as ECM components (nanosegments). PVA-IA films were selected as the base matrix due to easy regulation of elasticity (22 kPa-16.5 MPa) by changing the crosslinking time (15 min - 48 hr). AFSCs on soft substrates (22 kPa-1 MPa) had less spreading, fewer stress fibers and lower proliferation rate than AFSCs on stiff substrate (3MPa-16.5 MPa). The effects of interaction between AFSCs and ECMs (nanosegments) were investigated on the expression of pluripotent genes (e.g., Nanog, SOX2, and Oct4) of AFSCs and on the differentiation abilities of AFSCs into several lineage, which were cultured on PVA-IA films grafted with collagen, fibronectin, and vitronectin having different elasticity at passage 4. It was found that AFSCs on PVA-IA films grafted with ECM of elastic modulus (500 kPa-800 kPa) in the intermediate showed higher pluripotency genes than those on soft or hard substrates. AFSCs could differentiate into neural (nestin), smooth muscle cell (α-actin), or osteogenic (Runx2) phenotypes depending on whether they were cultured on PVA-IA films grafted with ECM substrates of elastic modulus in the lower, intermediate or higher ranges. AFSCs cultured on soft substrates
have weaker cell adhesion, and showed higher expression of early marker of neural cells (nestin) in expansion medium without addition of induction molecules.

INTERIM ANALYSIS OF 12 ALS PATIENTS TREATED WITH DIFFERENTIATED MESENCHYMAL STEM CELLS IN A PHASE I/II CLINICAL TRIAL SHOWS SAFETY AND SOME INDICATIONS OF CLINICAL BENEFIT

Daniel Offen[1], Panayiota Petrou[2], Marc Gotkine[2], Yael Gothelf[1], Yossef Levy[1], Adi Vaknin-Dembinsky[2], Zohar Argov[2], Tamir Ben-Hur[2], Eldad Melamed[1], Dimitry Karusiss[2]
[1]*Brainstorm Cell Therapeutics Ltd, Peta-Tikva, Israel,* [2]*Department of Neurology, Hadassah Hebrew University Medical Center, Jerusalem, Israel*

Background: Amyotrophic Lateral Sclerosis (ALS), also known as Lou Gehrig's disease, is a fatal, rapidly progressive neurodegenerative disease caused by motor neuron degeneration. Despite extensive efforts, no currently available treatment has been shown to slow down, halt, or reverse disease progression. Bone marrow-derived mesenchymal stem cells (MSC) represent an attractive cell source for the treatment of neurological diseases, with the potential to exert neuroprotection and possibly induce neurogenesis. We have previously demonstrated the neuroprotective effects of BrainStorm's NurOwn™ cells (Autologous Neurotrophic Factor (NTF)-secreting MSC, or "MSC-NTF") in various animal models of neurodegenerative diseases, including ALS. In the current study, we demonstrated the clinical safety and initial indications of clinical benefit of NurOwn cells in twelve ALS patients.

Aims: To evaluate the safety and tolerability of treatment with autologous MSC-NTF in ALS patients utilizing intramuscular (IM) injection of the cells in the early stage of the disease and intrathecal (IT) injection in patients with more advanced/progressive disease.
Methods: Bone marrow-derived MSC were isolated from twelve ALS patients, expanded ex-vivo and induced to secrete NTF using Brainstorm's NurOwn™ differentiation technology. These cells were transplanted via IM (at 24 sites: 2x105 cells per site) or IT (1x106 cells/kg) injections to patients with early (ALSFRS score of >30; n=6) or advanced ALS (ALSFRS: 15-30; n=6), respectively. Patients were monitored clinically on a monthly basis for 3 months pre-treatment and 6 months post-transplantation.
Results: During the six-month follow-up of the transplanted patients, no serious treatment-related adverse events were observed, indicating short-term treatment safety. The clinical follow-up of the patients also revealed initial indications of beneficial clinical effects in some of the MSC-NTF transplanted patients, as evidenced by a significant change in the rate of clinical progression (ALSFRS), respiratory function, electrophysiology and 3D-MRI volumetric evaluation of the muscles, as compared to the 3 months preceding the treatment.
Conclusions: Preliminary results of our Phase I/II ALS trial with autologous IM/IT transplantation of MSC-NTF indicate that single treatment at the current dosage appears to be safe. The initial indications of beneficial clinical effects may pave the way for future larger trials. Further analysis of the data and longer term follow-up of the participating patients are needed to confirm these observations.
Trial registration: ClinicalTrials.gov (ClinicalTrials.gov Identifier: NCT01051882). The study is sponsored by Brainstorm Cell Therapeutics Ltd.

APOLIPOPROTEIN A-I PROMOTES OSTEOGENESIS THROUGH STAT3 ACTIVATION AND AMELIORATES THE OVARIECTOMY-INDUCED BONE LOSS

Yu-chuan Liu
Genomic Research Center, Academia Sinica, Taipei, Taiwan

Apolipoprotein A-I (ApoA-I) is a major component of human high-density lipoproteins (HDLs) that remove cholesterol from arteries. The decrease of ApoA-I express levels increases the chances of cardiovascular disease, obesity, or other metabolic syndrome. By a high throughput screen, we identified ApoA-I can promote activity of early and late osteogenesis markers alkaline phosphatase (ALP) (6-8 fold) and Alizarin red staining (40 fold) in mesenchymal stem cells (MSCs). Furthermore, ApoA-I increased the expression of osteogenic markers RNA of ALP (18 fold) and bone sialoprotein (BSP) (6 fold). In addition, the phosphorylation of signal transducer and activator of transcription 3 (STAT3) and extracellular signal-regulated kinases (ERK) are both increased upon ApoA1 treatment. Inhibition of STAT3 activity or ERK activity by inhibitor diminished the effect of ApoA-I in osteogenic differentiation. ERK inhibitor also blocks STAT3 phosphorylation. Thus ERK may be the upstream regulator of STAT3. Meanwhile, we identified many cytokines stimulated by ApoA-I are regulated by STAT3. The knockdown of these cytokines blocks the osteogenesis of MSCs. The functions of these cytokines were not reported in ApoA-I-mediated pathways or bone formation before. In vivo, we further demonstrate that ApoA-I transgenic mice can prevent the osteoporosis in ovariectomized mice, a model mimic osteoporosis occurs in postmenopausal women. Osteoporosis is an important disease that indirectly leads to more death in peoples than breast cancer. One-third of the women and one-fifth of the men experience of osteoporotic fracture and the one-year mortality rate of hip fracture is 28-35%. Taken together, we find an ApoA-I-ERK-STAT3 pathway can promote osteogenic differentiation in vitro, and ApoA1 can prevent the bone loss in ovariectomized mice. This study not only identified a new ApoA-I-mediated pathways in bone formation, it may also provide several potential therapeutic targets for bone disease like osteoporosis or bone fracture.

BASIC FIBROBLAST GROWTH FACTOR- INDUCED FUNCTIONAL NEURONAL DIFFERENTIATION OF CANINE BONE MARROW STROMAL CELLS

Rei Nakano, Kazuya Edamura, Kenji Teshima, Kazushi Asano, Tomohiro Nakayama, Takanori Narita, Ken Okabayashi, Hiroshi Sugiya
Nihon University, Fujisawa, Japan

In the veterinary medicine, the clinical trial of spinal regenerative therapy using autologous bone marrow stromal cells (BMSCs) has been performed in dogs. However, the capacity of neuronal differentiation of canine BMSCs has not been well elucidated, although which is very important for the clinical application of canine BMSCs. In the previous studies, most of canine BMSCs died during or after the differentiation and it was obscure whether the differentiated cells had neuronal functions. In this study, we demonstrate that basic fibroblast growth factor (bFGF) is effective for differentiation of canine BMSCs into functional neurons.
Canine bone marrow was aspirated from the humerus of healthy beagle dogs. This study was conducted under Nihon University Animal Care and Use Committee approval. Mononuclear cells were separated by density gradient centrifugation using Histopaque-1077 (Sigma-Aldrich Inc.). The mononuclear cells were then static-cultured using α-MEM with 10% fetal bovine serum. On the fourth day of culture, non-adherent cells were removed when the culture medium was replaced, thus isolating the canine BMSCs. For neuronal induction, the canine BMSCs were incubated in Neurobasal-A medium (Life Technologies Co.) supplemented with 2% B27 supplement (Life Technologies Co.) containing bFGF (Immunostep: 100 ng/mL). Viability was assessed by trypan-blue exclusion. Real-time RT-PCR was performed to evaluate the expression of mRNAs of neural stem cell (NES), neuron (MAP2, NEFL, ENO2) and glia (GFAP) markers. To examine the cellular localization of neuronal markers, such as neurofilament light chain (NF-L) and neuron-specific enolase (NSE), immunofluorescence confocal microscopy was performed. To investigate whether the neuron-like cells from canine BMSCs were functional, we determined Ca^{2+}mobilization by using the Ca^{2+} indicator fluo-3.
When canine BMSCs were incubated with bFGF, viability of the cells was maintained up to 10 days. In the bFGF-treated cells, the mRNA expression of neuron markers such as MAP2, NEFL and ENO2 increased, while that of the neural stem cell marker NES and the glia marker GFAP decreased. The MAP2 mRNA expression induced by bFGF was completely inhibited by the FGFR inhibitor SU5402 (25 μM). The bFGF-treated cells exhibited round cell bodies and had several long, sharp processes like neurons. The expression of the neuron marker NF-L and NSE was confirmed in the bFGF-treated cells by immunocytochemistry. In the fluo 3-loaded bFGF-treated cells, KCl (50 mM) and $_L$-glutamate (100 μM) elicited an increase in intracellular Ca^{2+} levels, suggesting that voltage-dependent Ca^{2+} channels and glutamate receptors function in the cells.
Taken together, it is most likely that bFGF induces differentiation of canine BMSCs into functional neurons.

BONE MORPHOGENIC PROTEIN-2 SHOWS DIFFERENTIAL ACTIONS ON HUMAN ADIPOSE TISSUE AND BOME MARROW DERIVED MESENCHYMAL STEM CELLS

Sun Young Lee[1], Jee Young Kim[1], Da sol Kim[1], Yong Chan Bae[2], Keun Tak Suh[3], Jin Sup Jung[1]
[A]Physiology, [B]Plastic Surgery, [C]Orthopaedic Surgery, [1]School of Medicine, Pusan National University, Yangsan, Korea, Republic of

The bone morphogenetic proteins (BMPs) belong to a unique group of proteins that includes the growth factor TGF-β. BMPs play important roles in cell differentiation, cell proliferation, and inhibition of cell growth. BMPs can induce the differentiation of mesenchymal progenitor cells into various cell types, including chondroblasts and osteoblasts. The aim of this study was to analyze the effect of BMP-2 on the adipogenic and osteogenic differentiation of human adipose tissue- (hADSC) and bone marrow (hBMSC)-derived mesenchymal stem cells.BMP-2 increased osteogenic differentiation in human bone marrow-derived MSCs (hBMSC) without affect their adipogenic differentiation. Unexpectedly, BMP-2 increased adipogenic differentiation of hADSC without affecting osteogenic differentiation at an osteogenic differentiation condition. BMP-2 did not enhance adipogenic differentiation at an adipogenic differentiation condition. Real time PCR analysis showed that hADSC express BMP receptors and SMAD1 and 4, and that BMP-2 increased the expression of BMP2-responsive genes and induced SMAD1 phosphorylation in hADSC.

Proteome analysis showed that BMP2 increased adipogenesis-related protein levels. Downregulation of SMAD1 and 4 by the specific siRNAs transfection inhibited BMP2-induced increase of adipogenic differentiation in hADSC. At the condition that adipogenic differentiation was inhibited by the treatment of TNF-α, BMP2 stimulated osteogenic differentiation of hADSC. These data indicated that the control of osteogenesis and adipogenesis in MSCs are closely related, and that hADSC have preferential commitment into adipogenic lineages.

PANCREATIC EXTRACT PROMOTES BONE MARROW DERIVED MESENCHYMAL STEM CELLS DIFFERENTIATION INTO INSULIN PRODUCING CELLS

Hongbin Xie, Yunshuai Wang, Hui Qi, Hanxie Zhou, **Fu-Rong Li**
Laboratory of stem cell and Cellular therapy, The Second Clinical Medical College,Jinan University, Shenzhen, China

Mesenchymal stem cells can be successfully induced to differentiate into insulin-producing cells by a variety of small molecules and cytokines *in vitro*. However, problems remain, such as low transdifferentiation efficiency and poor maturity of transdifferentiated cells. The damaged pancreatic cells secreted a large amount of soluble proteins, which were able to promote pancreative islet regeneration and mesenchymal stem cells differentiation. In this study, we utilized the damaged pancreatic tissue extract to modulate mesenchymal stem cells differentiation into insulin-producing cells by the traditional two-step induction. Our results showed that damaged pancreatic tissue extract could effectively improve the transdifferentiation efficiency and maturity of insulin-producing cells by the traditional induction method.Our study provides a new strategy to induce an efficient and directional differentiation of mesenchymal stem cells into insulin-producing cells.

IN VITRO DIFFERENTIATION OF BONE MARROW DERIVED RAT MESENCHYMAL STEM CELLS TO NEURON-LIKE CELLS USING SPECIFICALLY DESIGNED NICHE

INDU S, TARA S
Thrombosis Research Unit, Sree Chitra Tirunal Institute for Medical Sciences & Technology, Thiruvananthapuram, India

Bone marrow mesenchymal stem Cells (BMMSCs) are adult multipotent stem cells which give rise to hematopoietic and non hematopoietic lineage cells *in-vivo*. Reports also indicate the differentiation of these BMMSCs into many cell types including cardiac, hepatic lineages. Even though, BMMSC differentiation into neuron-like cells (NLC) is reported, controversies exist regarding whether these cells truly represent neurons or not. The transplantation of neurons into injured/ degenerated sites is not effective in regenerative therapy as neurons are terminally differentiated cells. Since MSCs are multipotent, transplantation of these cells may not effective for achieving desired cell type at the site of injury. So precursors of neuron should be more appropriate for transplantation in regenerative medicine. This study hypothesizes that a cell-specific composition of bio mimetic matrix and culture medium together can support bone marrow derived neural progenitor cells (NPCs) for longer time in culture. The objective of the study was to identify the niche composition that can induce neural lineage commitment of BMMSC and support long term survival without phenotype drift.
The isolation and *in-vitro* culture of BMMSC from rat (Wistar) was done with IAEC approval. Briefly, Wistar rats (two month old) were sacrificed by CO_2

inhalation and the tibias and femurs were dissected out under sterile conditions. The bones were placed in HBSS buffer and were cleared of any muscle tissue using a sterile scalpel. DMEM F-12 medium containing 10% FBS was passed through the cut ends of the bone using a 18 G syringe and the marrow plugs were flushed out. The single cells obtained after re suspension were centrifuged at 400*g* for 5 min at 37°C. The bone marrow cells were seeded at a density of 25 x10^6 cells/ml DMEM F-12/25 cm^2 bare polystyrene surface (PS). For differentiation experiment, isolated, culture-expanded and characterized MSCs were plated on to the culture matrix. Matrix was prepared by clotting thin layer of fibrinogen composite, comprising fibronectin, hyaluronic acid, hypothalamus extract (HE) and platelet growth factors (PGF), on thrombin adsorbed PS. Differentiation was attempted using two media compositions viz; basic DMEM-F12-FBS containing (i) basic fibroblast growth factor (b FGF) [medium I] and (ii) HE and PGF [medium II]. Characterization of NLCs after defined periods of MSCs culture was done using immunocytochemistry. Homogeneity of BMMSCs was confirmed using positive markers; $CD90^+$, $CD44^+$, c-kit^+, $CD\ 105^+$ and negative marker $CD45^-$ using flow cytometry. Morphologically, healthy NLCs were observed in fibrin coated dishes in comparison to those found in uncoated dishes. The NLCs were positive for neuron specific markers like β-tubulin, MAP2 and synaptophysin at different stages of culture.. Media I and II supported the growth of NLCs; however enhanced NLC density was found in dishes containing medium II. The introduction of 2 mM Valproic Acid (VA) into medium II increased axonal elongation. NLC morphology showed minor changes upon prolonged culture. Long term maintenance of NLCs without any morphological changes was achieved by supplementing medium II with 2mM VA and minimal levels (2ng/mL) of FGF. **Conclusion:** Adhesive matrix and medium composition together created a cell specific niche that induced BMMSCs differentiation into NLCs and specific medium compositions supported their prolonged survival.

W-3077

DEVELOPMENT OF A 3D COLLAGEN GEL VASCULARIZED TISSUE-ENGINEERED CONSTRUCT FOR BONE REPAIR AND REGENERATION USING EMBRYONIC AND POSTNATAL PROGENITORS

Mani T. Valarmathi[1], Biechler V. Stefanie[2]

[1]Comparative Biosciences, University of Illinois at Urbana-Champaign, Urbana, IL, United States, [2]Cell Biology and Anatomy, University of South Carolina, Columbia, SC, United States

One of the major challenges in engineering complex tissues such as bone, which involves the reconstruction of 3D shapes and internal architectures, is the need to vascularize the tissue in vitro for functionally competent vascular networks. Vascularization in vitro could maintain cell viability during tissue growth, induce structural organization and promote neovascularization upon implantation. A method to enhance graft vascularization is to establish a primitive vascular plexus within the implant before transplantation by the use of cellular-based concepts. Consequently, this necessitates the formation of appropriate in vitro 3-D plexuses of new blood vessels within the pre-implanted biomaterial constructs through the process of in situ de novo vasculogenesis/angiogenesis for organ tissue engineering. It is well established that the process of neovascularization or neoangiogenesis is coupled to the development and maturation of bone. Bone marrow stromal cells (BMSCs) or mesenchymal stem cells (MSCs)

comprise a heterogeneous population of cells that can be differentiated in vitro into both mesenchymal and non-mesenchymal cell lineages. When both rat BMSCs and quail proepicardia (PEs) were seeded onto a three-dimensional (3-D) tubular scaffold engineered from aligned collagen type I strands and co-cultured in osteogenic media, the maturation and co-differentiation into osteoblastic and vascular cell lineages were observed. In addition, these cells produced abundant mineralized extracellular matrix materials and vessel-like structures. BMSCs were seeded at a density of 2 × 106 cells/15 mm tube and cultured in basal media for 3 days. Subsequently, on day 3, PEs were seeded onto the same tubes and the co-culture was continued for another 3, 6 or 9 days either in basal or in osteogenic media. Differentiated cells were subjected to immunohistochemical, cytochemical and biochemical analyses. Phenotypic induction was analyzed at mRNA level by reverse transcriptase quantitative polymerase chain reaction (RT-qPCR). Immunolocalization of key osteogenic and vasculogenic lineage specific markers were examined using confocal scanning laser microscopy. In osteogenic tube cultures, both early and late osteogenic markers were observed and were reminiscent of in vivo expression pattern. Alkaline phosphatase activity and calcium content significantly increased over the observed period of time in osteogenic medium. Abundant interlacing fascicles of QCPN, QH1, isolectin and α-smooth muscle actin (α-SMA) positive cells were observed in these tube cultures. These cells formed extensive arborizations of nascent capillary-like structures and were seen amidst the developing osteoblasts in osteogenic cultures. The 3D culture system not only generated de novo vessel-like structures but also augmented the maturation and differentiation of BMSCs into osteoblasts. Thus, this novel co-culture system provides a useful in vitro model to investigate the functional role and effects of neovascularization in the proliferation, differentiation and maturation of BMSC derived osteoblasts. We therefore demonstrate that under appropriate in vitro physicochemical microenvironmental cues (combination of growth facts and ECM) multipotent adult BMSCs in combination with embryonic-derived progenitors, on 3D collagen gel based scaffolds engineered from aligned collagen type I fibers in various media conditions to generate numerous vascularized tissues.

ENGAGING NATIVE CELLS WITH BIOINSPIRED MATRICES

Shyni Varghese, **Shih Yuru Vernon**, Yamaguchi Tomonori, Ameya Phadke, Masuda Koichi
Univ of California, San Diego, La Jolla, CA, United States

Advancements in stem cell biology and engineering offer unprecedented therapy for treating compromised tissues and cells. However, the challenge remains of how to effectively harness the therapeutic potential of stem cells to repair the targeted tissue/cell in vivo with control and precision. One of the widely recognized approaches involves transplantation of stem cells with the aid of delivery vehicles such as biomaterials, which provide structural support and instructive cues. Though biomaterials-assisted transplantation of cells is a promising approach to repair compromised tissues, developing systems that can activate endogenous stem cells and contribute to tissue regeneration are more clinically attractive. By employing a biomineralization approach, we have recently created a synthetic matrix emulating various functional attributes of native bone tissue. Human mesenchymal stem cells (hMSCs) and human embryonic stem cells (hESCs) cultured on these mineralized matrices underwent osteogenic differentiation in the absence of any osteogenic inducing soluble factors. Interestingly, when implanted in vivo, the acellular matrices recruited endogenous cells and formed vascularized bone tissue. Additionally, the acellular mineralized matrices also enabled fusion of decorticated transverse processes in a posterolateral lumbar fusion model. Radiographic and mechanical lateral bending analyses revealed that both cellular and acellular approaches promoted spinal fusion to a similar extent. Furthermore, we have employed these engineered matrices as an “artificial extracellular matrix” to understand the mechanism by which the calcium phosphate minerals induce osteogenic differentiation commitment of stem cells and the role of minerals on bone physiology. Perturbation of SLC201, a trans-membrane phosphate transporter, abrogates the matrix-induced osteogenic differentiation of hMSCs by decreasing intra-mitochondrial phosphate content and ATP synthesis. Moreover, adenosine, an extracellular ATP metabolite, was found to act as an autocrine and paracrine signaling molecule for osteogenic commitment of stem cells through A2b adenosine receptor. These findings begin to shed light on the role of ATP metabolism on bone homeostasis, which may be exploited to treat bone metabolic diseases. Furthermore, such biomimetic matrices that can activate endogenous cells and can control their fate to create functional tissues could have a significant

impact on regenerative medicine. Such synthetic matrix assisted tissue regeneration offers an easy-to-use therapeutic strategy to treat critical bone defects.

ACELLULAR CROSS-LINKED BOVINE PERICARDIUM COATED WITH NANOFIBERS FOR TISSUE ENGINEERING

Santosh Sadashiv Mathapati[1], Dillip Kumar Bishi[1], Jayarama Reddy Venugopal[2], Kotturathu Mammen Cherian[1], Soma Guhathakurta[1], Seeram Ramakrishna[3], Rama Shanker Verma[4]

[1]Stem cell and Tissue engineering, Frontier Life Line Pvt Ltd, Chennai, Chennai, India, [A]Nanoscience and Nanotechnology Initiative, Faculty of Engineering,, [B]Nanoscience and Nanotechnology Initiative, Faculty of Engineering, [2]National University of Singapore, Singapore, Singapore, [3]Stem Cell and Molecular Biology Laboratory, Department of Biotechnology, Indian Institute of Technology Madras, Chennai, India

Aim: Bovine pericardial tissues are widely used for the construction of a variety of bioprostheses. They are used to repair complex anatomical tissue defects arising out of cardiac and non-cardiac conditions such as soft tissue repair, abdominal wall defect, and strengthening the suture line during general surgical procedures. The present study is aimed at improving nanofiber coating of acellular tissue-engineered bovine pericardium (ATEBP) with biological polymers to nurture cells for tissue morphogenesis, improve adhesion and mechanical properties with the objective of directing cells for self-conclave in three dimensions. Such constructs confer exquisite functionality such as human mesenchymal stem cell (hMSCs) differentiation into endothelial cells (ECs) for tissue engineering.
Methods: Nanofibers of poly(L-lactic acid)-co-poly(ε-caprolactone) (PLACL) and also blend of PLACL/gelatin (PLACL/gelatin) were coated on with earlier developed acellular glutaraldehyde cross-linked detoxified bovine pericardium (ATEBP) scaffolds. Fabricated electrospun nanofibrous scaffolds were analyzed for fiber diameter, functional groups, hydrophilic or hydrophobic nature and mechanical properties. ATEBP coated with nanofibrous scaffolds were assessed for the proliferation of hMSCs and their differentiation into ECs.
Results: The ATEBP scaffolds coated with PLACL/gelatin nanofibres exhibited an increase in hydrophilicity and decrease in average fiber diameter and mechanical properties. The high porosity of PLACL/gelatin at above 70% is beneficial for the adhesion and proliferation of the hMSCs in addition to facilitating a homogeneous three-dimensional distribution of cells. Moreover, the increased gelatin content decreases fiber diameter, which leads to decreased porosity of scaffolds and biomechanical properties but enhanced cell adhesion, proliferation, and differentiation. The results showed that increased hMSCs adhesion, proliferation, and differentiation into ECs on ATEBP coated with PLACL/gelatin nanofibrous scaffolds compared to PLACL-coated ATEBP.
Conclusion: The ATEBP-coated nanofibrous scaffolds of PLACL/gelatin pave way for better hMSCs adhesion, proliferation, and differentiation into ECs to improve the therapeutic value of current soft tissue constructs in tissue engineering.

W-3082

INTRACAVERNOUS DELIVERY OF CLONAL MESENCHYMAL STEM CELLS RESTORES ERECTILE FUNCTION IN A MOUSE MODEL OF CAVERNOUS NERVE INJURY

Ji-Kan Ryu[1], Kang Moon Song[1], TacGhee Yi[2], Jun-Kyu Suh[1], **Sun U. Song**[2]

[A]Department of Urology, [B]Translational Research Center, [1]Inha University School of Medicine, Incheon, Korea, Republic of

Recently, much attention has focused on stem cell therapy; bone marrow-derived stem cells (BMSCs) are one of the most studied mesenchymal stem cells used in the field of erectile dysfunction (ED). However, a major limitation for the clinical application of stem cell therapy is the heterogeneous nature of the isolated cells, which may cause different treatment outcomes. We investigated the effectiveness of mouse clonal BMSCs obtained from a single colony by using subfractionation culturing method (SCM) for erectile function in a mouse model of cavernous nerve injury (CNI). Twelve-week-old C57BL/6J mice were divided into 4 groups: sham operation group, bilateral CNI group

receiving a single intracavernous (IC) injection of phosphate-buffered saline (PBS, 20 μL) or clonal BMSCs (3×10^5 cells/20 μL), and bilateral CNI group receiving a single intraperitoneal (IP) injection of clonal BMSCs (3×10^5 cells/20 μL). The clonal BMSC line was analyzed for cell-surface epitopes by using fluorescence-activated cell sorting and for differentiation potential by using *in vitro* differentiation assays. Two weeks after bilateral cavernous nerve crushing and treatment, erectile function was measured by electrically stimulating the cavernous nerve. The penis was harvested for histologic examinations and western blot analysis. Clonal BMSCs expressed cell surface markers for mesenchymal stem cells and were capable of differentiating into several lineages, including adipogenic, osteogenic, and chondrogenic cells. Both IC and IP injections of clonal BMSCs significantly restored cavernous endothelial and smooth muscle content in CNI mice. IC injection of clonal BMSCs induced significant recovery of erectile function, which reached 90-100% of the sham control values, whereas IP injection of clonal BMSCs partially restored erectile function. We established a homogeneous population of mouse clonal BMSCs using SCM; clonal BMSCs successfully restored erectile function in CNI mice. The homogeneous nature of clonal mesenchymal stem cells may allow their clinical applications.

W-3083

MESENCHYMAL STROMAL CELL DIFFERENTIATION TO ENDOTHELIAL CELLS: ROLE OF NOTCH SIGNALLING.

Samantha M. Roberts, Stephen G. Ball, Cay M. Kielty
Wellcome Trust Centre for Cell Matrix Research, University of Manchester, Manchester, United Kingdom

Notch signalling has been implicated in cell fate decisions and differentiation during vascular development, especially in branching angiogenesis and in the determination of arterial and venous fate. Previous investigations have also identified a role for Notch signalling in mesenchymal stromal/stem cell (MSC) differentiation towards an endothelial lineage (Whyte et al 2010). We are therefore investigating whether Notch signalling supports the endothelial differentiation of MSCs. MSCs seeded onto gelatine-coated 2D wells at high density demonstrated an increase in protein expression of the Notch 1 receptor intracellular domain and mRNA levels of the Hes and Hey transcription factors compared to low density MSCs. In addition a significant increase in the mRNA expression of the endothelial markers, PECAM-1, Tie2, VE-cadherin, von Willebrand factor and Vascular endothelial growth factor receptor 2, was observed after 96 hours in culture. Further increases in these endothelial markers were observed when MSCs were allowed to form spheroid bodies in which Notch signalling is highly active. Within the spheroids, the MSCs exhibited significantly higher levels of PECAM-1, Tie2 and Vascular endothelial growth factor receptor 2 protein expression after 96 hours in culture compared to the high density adherent cells. The effect of Notch signalling inhibition was assessed using the γ-secretase inhibitor DAPT, which resulted in a significant decrease in endothelial marker expression in MSCs cultured in both 2D and 3D high density culture models. Thus the observed increases in endothelial markers in these culture conditions are Notch-mediated. Ongoing studies are further investigating the mechanisms involved and the extent of endothelial commitment. In the future, we hope to modulate Notch signalling in order to differentiate MSCs down an endothelial cell lineage, for cell-based tissue regeneration therapies.

W-3084

SHEAR STRESS INDUCES ENDOTHELIAL LIKE PHENOTYPES IN PORCINE ASCS BUT FAILS TO INDUCE ENDOTHELIAL SURFACE MARKERS

Rafael Dariolli, Vinicius Bassaneze, Gabriela Venturini, Fernando Giugni, Jose E. Krieger
Laboratory of Genetics and Molecular Cardiology, Heart Institute - InCor - University of Sao Paulo Medical School, Sao Paulo, Brazil

Introduction: Adipose tissue-derived cells (ASC's) may have therapeutic applications in cardiovascular cell-based therapies despite the fact that they lack robust trandifferentiation potential. It is believed that the complex interplay between the implanted cells and the injured cardiac microenvironment may be essential for the understanding of their role in therapeutic cardiac protection. Aim: To evaluate the role of shear-stress (SS), one of the phys-

ical forces important for maintenance of cardiovascular homeostasis, on pASCs in vitro. Methods: The pASC immunophenotype was analyzed by flow cytometry. SS experiments were performed using the well-established cone-plate viscometer system. Nitric Oxide (NO) production was assessed by the amount of nitrate and nitrite accumulation in the media of sheared and static cells using the colorimetric Griess assay. The cytokine VEGF-A was measured by ELISA assay. Results: pASC exposed to SS displayed an uncommon LiCl-reversible alignment and GSK-3β phosphorylation after 24 hours, but failed to express endothelial cell (EC) markers (CD31, VE-cadherin, and FLK-1). The SS stimuli resulted in nitric oxide (NO)-induced VEGF accumulation (15dyn/cm², up to 96 hours). Interestingly, SS-induced phosphorylation of ERK and AKT and the release of NO were independent of the magnitude of the stimulus (1-3, 5, 10, 15 and 25-30 dyn/cm², up to 30 minutes). In contrast, long-time (24-48 hours) SS-induced NO and VEGF release in response to 5 dyn/cm² was higher than that in response to 10 or 15 dyn/cm2. Conclusion: Altogether, we provided evidence that the SS induces endothelial-like phenotypes, such as, modulation of NO and VEGF release and morphological alteration despite the fact that pASC failed to express endothelial cell surface markers in vitro. The efficacy of the pre-exposure of transplanted cells for therapeutic purposes to stimuli, such as, SS deserves to be further explored.

TRANSMYOCARDIAL REVASCULARIZATION ENHANCES MESENCHYMAL STEM CELL ENGRAFTMENT IN INFARCTED HEARTS THROUGH STEM CELL FACTOR--C-KIT (SCF--C-KIT) AND STROMAL DERIVED FACTOR-1--CHEMOKINE RECEPTOR TYPE 4 (SDF-1--CXCR4) SIGNALING AXES

Uswa Shahzad, Guangming Li, Terrence M. Yau
Division of Cardiovascular Surgery, Peter Munk Cardiac Centre, University Health Network, Toronto, ON, Canada

Transmyocardial Revascularization Enhances Mesenchymal Stem Cell Engraftment in Infarcted Hearts Through SCF–c-kit and SDF-1—CXCR4 Signaling Axes

Objective

We have previously demonstrated that transmyocardial revascularization (TMR) enhances postinfarction myocardial repair by mesenchymal stem cell (MSC) transplantation via signaling to circulating progenitor cells. This was associated with upregulation of components of the stem cell factor (SCF)–c-kit signaling axis and stromal derived factor-1 (SDF-1)–chemokine receptor type 4 (CXCR4) axis. We therefore investigated the roles of the SCF–c-kit and SDF-1–CXCR4 stem cell signaling axes in TMR-augmented repair of infarcted hearts.

Methods

Three weeks after LAD ligation, female Lewis rats underwent 10-channel needle TMR, followed by daily IV injections of 1 million male donor MSCs for 5 days, either wild type (WT) or with knockdown (K/D) of c-kit or CXCR4, accomplished via a shRNA+plasmid in a lentiviral vector. Experimental groups included: WT MSC with or without TMR, c-kit K/D MSC with or without TMR, and CXCR4 K/D MSC with or without TMR (N=6/group). Gene expression was evaluated by quantitative PCR and LV function by echocardiography.

Results

Flow cytometry revealed that *in vitro* cell surface expression of c-kit (N=3) was reduced from 14±0.7% of WT MSCs to 1.6±0.4% in c-kit K/D MSC after one week ($p<0.05$). Similarly, CXCR4 expression (N=3) was reduced from 39±10% of WT MSCs to 3.7±0.7% of CXCR4 K/D MSC at one week ($p<0.05$). Thus, knockdown dramatically reduced receptors key to stem cell signaling.

In our rat infarct model, 3 days after the last MSC injection, the number of MSCs that had homed into the infarct was affected by both TMR and donor cell type, with greater MSC engraftment with TMR and with WT MSC (TMR, cell type, and interaction, $p<0.05$). At 1 week, these differences persisted (TMR and cell type, $p<0.05$).

At 3 days, TMR significantly upregulated transcription of c-kit (TMR, $p<0.05$), SCF (TMR and cell type, $p<0.05$), CXCR4 (TMR and cell type, $p<0.05$), and SDF-1 (TMR and cell type, $p<0.05$). At 1 week, we saw similar declines in expression of c-kit (cell type, $p<0.05$), SCF (TMR, $p<0.05$), CXCR4 (TMR and cell type, $p<0.05$), and SDF-1 (TMR, $p<0.05$).

At 1 week, TMR improved LV ejection fraction (LVEF) (N=5) when WT MSCs were infused, but knockdown of either c-kit or CXCR4 completely abrogated this TMR-mediated augmentation of MSC reparative effect (TMR and cell type, $p<0.05$).

Conclusions

Cell surface expression of c-kit and CXCR4 in MSC is significantly decreased after *ex vivo* knockdown. Downregulation of either c-kit or CXCR4 in MSC decreased homing and engraftment of circulating MSC and inhibited the reparative effects of TMR. Knockdown of either c-kit or CXCR4 completely eliminated TMR-induced improvement of LVEF. Hence, both SCF–c-kit and SDF-1–CXCR4 signaling axes are required for TMR-augmented repair of the infarcted heart. We speculate that variability in stem cell signaling axes and efficacy may also underlie variable clinical responses to TMR in patients.

W-3086

A NOVEL APPROACH FOR THE TREATMENT OF STERILITY USING MESENCHYMAL STEM CELLS ISOLATED FROM MICE'S BONE MARROW

Sherif N. Amin, Hisham H. Issa, Nora A. Khan, Odai Abushalbaq, Walaa Bajaber
general, cell safe bank, cairo, Egypt

Sterility is the failure of sexual active, disabilities of couples to accomplish pregnancy after one year of unprotected intercourse which considered as problem in the society due to its high prevalence rate. Male cause for sterility found in 50% of couples.This research focuses on extracting stem cells from mice bone marrows and expanding them to obtain mesenchymal stem cells that will be then utilized for the treatment of sterility. Mice were first dissected to obtain their femurs and tibiae, which is followed by extraction of cells from bone marrow of these bones. After that, Mesenchymal stem cells were cultured on Mesenchymal stem cell expansion medium and expanded in several subcultures followed by detection and quantitation using flow cytometry in order to be used for treatment of mice infertility. sterile mice were injected with mesenchymal stem cells. after 3 weeks these mice were dissected to study the effect of mesenchymal stem cells on these sterile mice. Results showed that the extracted mesenchymal stem cells from bone marrow showed positive growth and differentiation under specific culture conditions after several subcultures in which these cells were detected and quantified as CD90+ using flow cytometry, which is a main characteristic cell marker of Mesenchymal stem cells. moreover, histochemical results showed minimal spermatogonial cells after dissection of mice. in conclusion mesenchymal stem cells might be of future use in treatment of sterility but with the help of extensive studies in this field.

W-3087

CHARACTERIZATION OF SYNOVIUM-DERIVED CANINE MESENCHYMAL STEM CELLS (MSCS) USING CHEMICALLY DEFINED SERUM FREE MEDIA STK1 AND STK2

Satoshi Maeda[1], Minoru Morikawa[1], Shin-ichi Hasegawa[2], Jinchang Shao[2], Yui Kitayama[1], Masato Takao[3], Shinya Miki[3], Ken-ichiro Nakajima[3], Ken Innami[3], Koichiro Tsuji[2], Takashi Matsushita[3]
[1]Tokyo Lab/Office, Two Cells Co., Ltd., Tokyo, Japan, [2]R&D division, Two Cells Co., Ltd., Hiroshima, Japan, [3]Department of Orthopaedic Surgery, Teikyo University School of Medicine, Tokyo, Japan

Mesenchymal stem cells (MSCs) derived from synovium are widely
investigated for cartilage repair because of higher capacity in self-renewal
and chondrogenesis, comparing with MSCs from bone marrow and adipose tissue. In medical application, animal models are known to be crucial for preclinical evaluation of safety and effectiveness. However, larger animal models like canine haven't fully been investigated on preclinical effects of MSCs yet. In this study, we performed the characterization on cell surface markers of canine synovial MSCs and showed their differentiation potentials, using chemically defined serum-free media STK1® and STK2®, which we developed previously, comparing with DMEM containing 10 % fetal bovine serum (DMEM-10% FBS).Synovial membranes were picked out from rear knee joints of male

beagle dogs (11 months old) under arthroscopic surgery. They were then enzymatically digested with 0.4% collagenase at 37 °C for 90 min. The nucleated cells isolated from the tissues were cultured in STK1® in primary culture, and recovered as adherent cells. Subsequently, they were cultured in STK2® in subsequent passage culture. For osteogenic and adipogenic differentiations, the MSCs were changed to respective differentiation medium after confluency. For chondrogenic differentiation, MSCs were pelleted by centrifuge and then cultured in chondrogenic medium.The MSCs cultured by STK series media were adherent, spindle-shaped and fibroblast-like cells, expressing the pluripotency markers such as Oct3/4, Nanog, and Sox2 for about one month-expansion until passage 5 (P5). The MSCs cultured in STK series media showed higher proliferative potential, comparing with those grown in DMEM-10% FBS. In flow cytometric analysis in P3, these cells expressed surface markers, including CD29 and CD44, but did not detect CD14, 34, 45, or HLA-DR. Furthermore, it is interesting that either CD73 or CD105, defined as human MSC positive markers, was not detected. Osteogenic and adipogenic differentiations were demonstrated by staining with Alizarin Red S and Oil Red O in 21 day-cultures, respectively. Osteogenesis was also determined by elevated alkaline phosphatase activity. The cell pellets for chondrogesis were increased in size gradually and showed higher gene expression associated with the chondrogenic marker such as Sox9, Aggrecan, and Type II collagen in quantitative RT-PCR. These results indicate that the phenotype of canine MSCs derived from synovium is not necessarily consistent with that of human MSCs, and that the cytochemical stainings revealed that canine MSCs also have the multipotency in the same manner as human. In addition, it is found that their differentiation potential is improved by using STK1® and STK2®, comparing with DMEM-10% FBS. Because STK1® and STK2® are chemically defined serum free media, MSCs grown in these media are useful in in vivo studies on canine cartilage defect model, in order to obtain more obvious effectiveness with safety in transplantation.

TAUROURSODEOXYCHOLIC ACID ATTENUATES LIPID ACCUMULATION AND ADIPOGENESIS OF MESENCHYMAL STEM CELLS BY MODULATING ER STRESS

Byung Hyun Cha, Jong Chan Ahn, Jin-Su Kim, Hee-Chun Kim, Sang Gyu Park, Soo-Hong Lee
Department of Biomedical Science, CHA University, Seongnam-si, Korea, Republic of

The obesity has become a serious health problem of modern people. Increased adipose mass in obesity is due to an increase in size (hypertrophy) of adipocyte and number (hyperplasia) of adipocyte. Chemical chaperone, tauroursodeoxycholic acid (TUDCA) not only has the ability to decrease endoplasmic recticulum (ER) stress, also plays a role as leptin-sensitizing agents at preadipocyte in the obese mice and human models. In this study, we examined whether TUDCA affects human mesenchymal stem cells (MSCs) such as bone marrow and adipose derived stem cells. To aim this, ER stress, lipid accumulation and adipogenesis of MSCs were observed by histological staining, RT-PCR and western blotting. Osteogenesis and chondrogenesis were also evaluated. TUDCA treatment significantly decreased ER stress and adipogenic differentiation of MSCs, however, did not affect osteogenic and chondrogenic differentiation. Likewise to preadipocyte, these demonstrate TUDCA plays a critical role to adipogenesis of MSCs by modulating ER stress. Thus, this novel finding suggests a new mechanism on MSCs to chemical chaperons such as TUDCA and would be useful for pharmacological and therapeutic applications against obesity.

SINGULAR CELL CERAMIC CONSTRUCT MEDIATED OSTEOCHONDRAL INTERFACE ENGINEERING

Francis B. Fernandez, Sachin J. Shenoy, Suresh B. Babu, H K Varma, Annie John
Transmission Electron Microscope Lab, Sree Chitra Tirunal Institute for Medical Sciences & Technology, Thiruvananthapuram, India

Articular Cartilage damage is difficult to address with current surgical & therapeutic strategies. The native organization of hyaline cartilage tissue that renders it ideal for weight bearing & joint articulation via an avascular, low cell count structure also hinders healing. Post-intervention via conventional techniques generate fibrous tissue which is not commensurate in quality & integration with native tissue structures. The current study aims at understand-

ing adipose-derived stromal cell differentiation mediated by hydroxyapatite-based scaffolds that mimic bone structures to optimize & address cartilage defects caused by disease, trauma or degeneration.
Hydroxyapatite (HA) forms the native mineral component of bone & altered states of the same via a patented indigenous process is used as scaffold material -
(1) HASi - Hydroxyapatite coated with Silica
(2) BCP - Biphasic Calcium Phosphate (BCP) containing a graded ratio of HA to beta-tricalcium phosphate content.
HASi and BCP scaffolds were evaluated for its physico-chemical characteristics via Scanning Electron Microscopy (SEM), Fourier Transform Infra - red Spectroscopy (FT-IR) and X- Ray Diffraction (XRD). SEM images depicted the structural integrity and porous interconnected architecture (50 - 500 microns pore sizes) ideal for cellular infiltration and habitat. FT-IR detected the functional phosphate and silca groups and X-ray diffraction (XRD) pattern exhibited crystallinity with hydroxyapatite as the major phase in all the materials.
Adipose-derived stromal cells isolated from New Zealand White (NZW) Rabbit (RADMSC) were characterized, differentiated into the desired osteogenic & chondrogenic lineages and tested for compatibility with the prepared scaffolds. HASi and BCP proved to be non-cytotoxic and cytocompatible in direct contact with RADMSCs and their osteogenic & chondrogenic potential was utilized for defect healing.
For *in vivo*, cylindrical HASi and BCP tailored to defect dimensions were seeded with spatially segregated osteogenic & chondrogenic cells. Cell loaded scaffolds were implanted into 3.5mm (dia.) and 4mm (deep) defects in the medial femoral condyles of 6 month old NZW rabbits for 3 & 6 months. Defects at 6 months showed a lack of surface fibrillation or disarray as observed in similar long term weight bearing defect trials. Retrieved samples (3 months & 6 months post implantation) indicated progressive surface reorganization via Micro - CT (Contrast Enhanced - Hexabrix). Further details were elicited of near complete cartilage re-organization via stained plastic sections with material *in situ*. Sections were stained with Stevenal's Blue & Van Gieson's Picrofuchsin to demonstrate cartilage regeneration & bone formation. This was supported by studying integration of scaffolds into subchondral trabecular bone via Back Scatter Electron imaging
Studies on osteochondral reconstruction have popularly used bone marrow-derived mesenchymal stem cells in conjunction with polymeric scaffolds. Here, an attempt to combine easily accessible adipose-derived stromal cells in combination with a bone-integrating ceramic scaffold for smooth overgrowth of articular tissue is undertaken. The promising results open a unique pathway for future studies in this niche of novel bone supported cartilage reconstruction in Interfacial Osteochondral Engineering.

CONTRIBUTION OF HUMAN MESENCHYMAL STROMAL CELLS TO DECELLULARIZED LUNG SCAFFOLDS

Julio J. Mendez, Mahboobe Ghaedi, Laura E. Niklason
Anesthesiology, Yale University, New Haven, CT, United States

Identifying appropriate cell sources to use in the recellularization of decellularized lungs is paramount in constructing a viable tissue engineered organ. To this end, we have investigated the potential of using human mesenchymal stromal cells as donor cells for tissue engineered lungs. Human bone marrow-derived mesenchymal stromal cells (hBM-MSCs) and human adipose MSCs (hA-MSCs) were isolated from freshly harvested bone marrow samples, or from abdominal fat lipoaspirate, respectively. FACS characterization of early passage cells demonstrated that both the hBM-MSCs as well as the hA-MSCs express the canonical MSC markers including CD90, CD105, and CD73, while being negative for CD45 and CD11b. Interestingly, both adipose and bone marrow derived MSCs also expressed markers associated with lung epithelium including CCSP, Pro-SPC and cytokeratin 5. In general, hA-MSCs contained fewer cells that were positive for both CCSP and pro-SPC following culture on plastic when compared with hBM-MSCs, whereas both had similar levels of cytokeratin 5 positive cells. MSCs from adipose and bone marrow were seeded onto decellularized rat lungs and cultured in a lung bioreactor for 7 days in small airway growth medium. After culture, both MSC sources resulted in robust coverage of the recellularized organ. Lungs recellularized with hBM-MSCs maintained expression of the type 2 pneumocyte marker, Pro-SPC as well as cytokeratin-5, while being negative for other lung epithelial markers including CCSP, p63, and caveolin 1. Co-culture experiments within the lung bioreactor allowed for the seeded cells to further differentiate towards cells that express markers of type 1

pneumocytes, including caveolin 1 and aquaporin 5, and more rarely to cells that expressed the Clara cell marker, CCSP. Together, these data indicate that mesenchymal stromal cells have the capacity for differentiation into lung epithelium when placed onto decellularized rat lungs, and further allows for the possibility of using MSCs as a potential cell source for tissue engineered lungs.

W-3093

PROTEOMIC PROFILING OF DIFFERENTIALLY EXPRESSED PROTEINS IN TOLL-LIKE RECEPTORS 3- AND 4-PRIMED MESENCHYMAL STEM CELLS

Mi Ran Choi, Mi Sook Doh, Sun Hwa Kim, Kyoung Hwa Jung, Young Gyu Chai
Department of Molecular & Life Sciences, Hanyang University, Ansan, Korea, Republic of

A variety of stimuli including inflammation stimulate expression of toll-like receptors (TLRs) in human bone marrow-derived mesenchymal stem cells (MSCs), resulting in the activation of TLRs' immune modulatory mechanisms. In the present study, MSCs were led to TLRs 3- and 4-primed cells by exposing them to poly(I:C) and LPS, respectively. And, the proteins up- and down-regulated in the cells were analyzed using proteomic techniques. We observed that rantes, IP10 and indoleamine 2, 3-dioxygenase were highly expressed in TLR3-primed cells, while IL6, IL8 and IL4 were highly expressed in TLR4-primed cells. Our proteomic analysis identified that 21 proteins including lysine degradation pathway associated proteins (2-oxoglutarate dehydrogenase precursor, procollagen-lysine,2-oxoglutarate 5-dioxygenase 2 isoform 1), focal adhesion proteins (type VI collagen alpha 2 chain precursor, filamen B) and peroxiredoxin 6 were up-regulated in TLR3-primed cells but down-regulated in TLR4-primed cells compared to MSCs. On the other hand, TLR3-primed cells showed the higher expression of proteolipid protein 2, pre-mRNA-processing factor 19, E3 ubiquitin-protein ligase LRSAM1 isoform 1 and liprin alpha4 proteins compared to TLR4-primed cells and MSCs. TLR4-primed cells showed down-regulated levels of neurabin-2, elongation factor 2 and heat shock protein 60 whereas vimentin and diacylglycerol kinase (theta) were up-regulated. These results show that stimulation of TLR3-priming in MSCs promotes the expression change of proteins responsible for protein polyubiquitination, cell motion and focal adhesion, while TLR4-priming induces the expression change of proteins associated with oxidation reduction and protein folding.

ELONGATED STEM CELL MORPHOLOGY AND MATRIX STIFFNESS INFLUENCES LINEAGE BY MODULATING CONTRACTILITY

Ludovic G. Vincent
Bioengineering, UCSD, LA JOLLA, CA, United States

Myosin-mediated contractility has become a well-documented mechanism by which adult mesenchymal stem cells (MSCs) detect extracellular matrix (ECM) properties, e.g. stiffness, porosity (to control cell shape), etc., and respond by differentiating. ECM cues including stiffness and shape are usually synergistic, but fibrotic diseases alter stiffness, creating an imbalance in cues and thus aberrant contractility. We hypothesized that these cues could be "rebalanced" to a new optimum where appropriate myosin-mediated contractility is regained and MSC differentiation towards one lineage can be restored, i.e. highy elongated cells despite an abnormally stiff microenvironment to initiate myogenesis. To "rebalance" ECM cues, MSCs were plated on fibronectin patterns of varying aspect ratio but common area on compliant as well as abnormally stiff substrates that normally would or would not be permissive for myogenesis, respectively. MSCs expressed muscle specific myosin heavy chain (MHC) most strongly on compliant, muscle-like stiffness and elongated patterns with 10:1 and 15:1 aspect ratio. In contrast on abnormally stiff substrates, highest MHC expression corresponded to square and circle shaped cells. Cell contractility scaled with stiffness and decreased with increasing cell aspect ratio; square-shaped cells on abnormally stiff substrates, which were muscle MHC positive, produced the highest contractile energy rather than an optimal contractility observed for unpatterned MSCs on compliant substrates where muscle induction normally occurs. These data suggest that despite expression of muscle markers, contraction "rebalancing" is more complex than proposed. Indeed, expres-

sion and assembly of focal adhesion proteins such as vinculin, which transmit contractions, scaled more with cell shape than stiffness; highly elongated cells expressed the most vinculin but were the least contractile, suggesting that perhaps the force per focal adhesion could dictate differentiation via a focal adhesion-based sensor such as vinculin. However when induction media is used, differentiation was observed on all shapes and stiffness though highest when ECM and induction media were working synergistically towards one lineage. These data suggest that focal adhesion signaling pathways are unique to ECM-mediated induction, but overall, they suggest that lineage induction may be possible in non-permissive ECM niche, which could prove beneficial to treat fibrotic diseases.

TRANSCRIPTION FACTOR NETWORK DYNAMICS IN EARLY OSTEOGENIC AND ADIPOGENIC COMMITMENT OF HUMAN MESENCHYMAL STROMAL CELLS

Jeroen van de Peppel[1], Tanja Strini[1], Marco Eijken[3], Peter van der Spek[2], Hans van Leeuwen[1]
[A]Internal Medicine, [B]Bioinformatics, [1]Erasmus MC, Rotterdam, Netherlands, [2]Arcarios bv, Rotterdam, Netherlands

Aging of the human skeleton is characterized by a decrease in bone mass due to increased bone resorption by osteoclasts and uncoupled bone formation by osteoblasts. A striking phenomenon is the increase of bone marrow adipocytes upon aging and in patients with osteoporosis. As osteoblasts and adipocytes share a common progenitor in the bone marrow (Mesenchymal Stromal Cells, MSCs), we wanted to understand the early regulatory events that occur upon differentiation of human MSCs. Identification of early transcription factors (TFs) and the regulation of target genes could expand our knowledge of lineage decision and commitment of hMSCs. Moreover, efficient differentiation will further improve the use of hMSCs in regenerative therapies.
To address this question, we have differentiated hMSCs into Osteoblasts (Dexamethasone , b-Glycerophosphate) and Adipocytes (Dexamethasone, IBMX, Indomethacin), isolated RNA and analyzed the transcriptome in a high temporal resolution using Illumina microarrays. Our analyses illustrate that gene expression changes upon differentiation of hMSCs into adipocytes or osteoblast were very dynamic. Based on these changes and unsupervised cluster analyses we could identify 3 differentiation phases within the first 4 days: 1) 0 to 3hrs, 2) 6hrs to 1 day and 3) 2 to 4 days. Interestingly, genes changing within the first phase were highly enriched for genes involved in transcription regulation, transcription factor activity and DNA-binding and suggested an important role for TFs in the initial differentiation phase.
To further investigate the TF network dynamics during lineage commitment, we concentrated on the TFs that changed their activity immediately upon differentiation (first phase). Using IPA's Upstream Regulator Analyses (Ingenuity Systems) we identified 33 TFs that changed activity within the first 3 hours of differentiation based on the regulated genes in this phase. Nine TFs were (in)-activated upon differentiation in both lineages and contained the dexamethasone activated glucocorticoid receptor and the cell cycle regulator CDKN2A. Four and 20 TFs changed activity when hMSC were differentiated into osteoblasts or adipocytes, respectively. Several of these TFs have not been described for their effects on osteogenic or adipogenic differentiation. However, knockout models described in literature have observed growth, skeletal, immune system and metabolic phenotypes that might be related to defective differentiation and lineage commitment of MSCs in vivo. Moreover, these TFs are associated with signaling pathways such as Glucocorticoid receptor, Aryl hydrocarbon receptor, Prolactin, ERK/MAPK and Wnt/b-Catenin signaling. Currently we are functionally characterizing the identified TFs in the initial phase of MSC commitment and will present here the effects of overexpression and interacting proteins of the identified TFs complexes.
Taken together, these in depth transcriptional analyses of differentiating hMSC increased our understanding of lineage decision/commitment. We have identified transcription factors that were (in)-activated upon differentiation of hMSC and can be key regulators for lineage decision holding potential for controlling bone formation.

TRANSDIFFERENTIATION OF MOUSE ADIPOSE-DERIVED STROMAL CELLS INTO PRESUMPTIVE SALIVARY ACINAR CELLS BY CO-CULTURE SYSTEM

Jin-gu Lee, SangKyu Park, Sangho Roh
Cellular Reprogramming and Embryo Biotechnology Laboratory, College of Dentistry, Seoul National Univ., Seoul, Korea, Republic of

A irreversible loss of salivary gland function often occurs after radiation therapy in head and neck tumors, and transplantation of salivary acinar cells (SACs), in part, may overcome the side effect of the therapy. Recently, SACs were successfully differentiated from human amniotic epithelial cells (hAECs) and bone marrow stromal cells (BMSCs) by co-culture system and the cells are expressed the markers of SACs such as alpha-amylases, mucins and aquaporin 5. Here we used mouse adipose-derived stromal cells (ADSCs) as the cell source to differentiate directly into SACs using co-culture system. ADSCs have the ability of multipotency and can be easily collected from stromal vascular fractions of adipose tissues. The isolated ADSCs were cultured in DMEM supplemented with 20% fetal bovine serum (FBS, v/v), 1% non-essential amino acids and fibroblast growth factor-2 (5 ng/ml). The cultured ADSCs showed positive expression of their markers such as integin beta-1 (CD29), cell surface glycoprotein (CD44), endoglin (CD105) and nanog. The cells were able to differentiate into adipocytes after 2~3 week of culture and this was confirmed by lipid vesicles in their cytoplasm after Oil Red-O staining. Then, the ADSCs (2 X 104 cells/well) at passage 2 were co-cultured with mouse SACs (8 X 104 cells/well) in acinar's culture medium (DMEM/F12 with 20% FBS and 10 ng/ml epidermal growth factor) using the double-chamber system to avoid the mixture of those two types of cells, and the ADSCs were successfully differentiated to presumptive SACs in this co-culture system. Detailed results will be presented at the meeting. This study was supported by a grant from the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (MEST; 2012-0006145) and Technology Development Program for Agriculture and Forestry, Ministry for Food, Agriculture, Forestry and Fisheries (MIFAFF; 111160-04), Republic of Korea.

TRANSIENT VASCULARIZATION DIRECTS INTRINSIC CARTILAGE FORMATION FROM HUMAN PROGENITORS

Takanori Takebe, Shinji Kobayashi, Mitsuru Mizuno, Hiromu Suzuki, Yu-Min Chang, Emi Yoshizawa, Jiro Maegawa, Hideki Taniguchi
Yokohama City University, Yokohama, Japan

Craniofacial deformations caused by anomalies or traumas affect millions of patients worldwide. Current surgical interventions provide limited therapeutic outcomes; therefore, one promising approach involves the use of reconstructed cartilage grafts that utilize autologous mesenchymal progenitors. Adult cartilage is a unique avascular, aneural and alymphatic tissue. Despite the simplicity of this tissue, decades of study failed to direct homogenous cartilage tissues from transplanted mesenchymal progenitors. More specifically, only a limited population of progenitors successfully underwent mature chondrocyte differentiation in vivo, resulting in calcification or fibrocartilage formation. Here, we report that transient vascularization provides an important directional cue for progenitors to stimulate efficient chondrogenesis. Using an intravital imaging approach, we unexpectedly found that avascular cartilage development was promoted by initial vascularization and subsequent vessel regression. By recapitulating transient vascularization, we established a simple and highly efficient technique for regenerating human elastic cartilage. Elastic cartilage was quickly and efficiently grown from recently identified adult ear-derived human cartilage progenitor cells relative to conventional pellet culture transplants. By this approach, we generated three-dimensional (3-D) human elastic cartilage from progenitors without the use of the expensive exogenous factors or scaffolding materials that have been considered essential to the classical concept of tissue engineering. Cartilage regenerative therapies offer a promising approach for millions of patients with craniofacial deformations caused by anomalies or traumas, and the transplantation of vascularized cartilage progenitor cells provides a new potential method for efficient cartilage reconstruction in future clinical treatments.

W-3098

WNT ANTAGONIST sFRP4 INHIBITS THE ANGIOGENIC POTENTIAL OF HUMAN AMNION DERIVED MESENCHYMAL STEM CELLS

Sudha Warrier
Cardiovascular Regeneration, Manipal Insititute of Regenerative Medicine, Bangalore, India

The canonical Wnt/beta-catenin signaling pathway has been demonstrated to play an essential role in stem cell fate and in developmental angiogenesis. Genetic studies have implicated the Wnt/Frizzled (Fz) molecular pathway, namely Wnt7B and Fz4, in blood growth regulation. Mesenchymal stem cell (MSC) transplantation offers a robust source of angiogenic regeneration in vascular regenerative medicine. We have previously identified that MSCs from an avascular amnion have an inherent propensity for promoting angiogenesis by undergoing rapid vascularization and could be an ideal choice in wound healing and diseases that require rapid vascularization and tissue restoration. In the present study, we investigated the role of secreted frizzled related protein 4 (sFRP4), a modulator of the Wnt/Fz pathway, in regulating the angiogenic potential of amnion-derived MSCs (AMMSCs).
In our previous study, sFRP4 was shown to be a potent inhibitor of angiogenesis of endothelial cells. However, the effect of sFRP4 on MSCs with respect to their differentiation into the endothelial lineage has not been studied so far. Using various in vitro assays such as the endothelial ring formation assay, chemotactic assay and endothelial wound scratch assay, we established that sFRP4 inhibits endothelial cell differentiation and migration of AMMSCs. It also disrupted the stability of endothelial rings and retarded proliferation of MSCs. Mechanistic analysis of the action of sFRP4 was done by functional assays such as the effect of LiCl, quantification of ß catenin levels by Western blot, determination of intracellular calcium, superoxide levels, and catalase assays on sFRP4 mediated angiogenic inhibition of MSCs. From these analyses, we demonstrate that sFRP4 is able to block Wnt signaling via the canonical ß- catenin pathway. Furthermore, these functional data also reveal that sFRP4 also activates the Wnt/Calcium pathway. Induction of apoptosis of differentiated endothelial cells could be related to the activation of cellular reactive oxygen species.
These studies pave the way for understanding the role of sFRP4 in developmental angiogenesis. These results also suggest the use of sFRP4 as a potent angiogenic inhibitor of MSC mediated angiogenic differentiation in the context of the tumor microenvironment where pro-angiogenic factors secreted by MSC promote angiogenesis and tumor growth. Thus, targeting this interaction may lead to novel therapeutic and preventive strategies.

W-3101

GENERATION AND CHARACTERIZATION OF OOCYTE-LIKE CELLS DERIVED FROM HUMAN AMNIOTIC FLUID STEM CELLS

Xiaoli Yu, Huayan Wang
Dept. Biotechnology, Northwest A&F University, Yangling, China

Embryonic stem cells (ESCs) and induced pluripotent stem cells (iPSCs) cultured in appropriate environment have the ability to differentiate into oocyte-like cells (OLCs), which recruit adjacent cells to form follicle-like structures. OLCs were use to generate the live offspring after reconstituted with female gonadal somatic cells. However, the long term of transformation and the low efficiency to obtain OLCs have restricted their availability for experimental use. To improve the efficiency of OLC generation, human amniotic fluid stem cells (hAFSCs) were used as an oogenesis model. The $CD117^{+}/CD44^{+}$ hAFSCs showed the fibroblastoid morphology and has been propagated for more than 45 passages and maintained the multipotency and potential to differentiate into three germ layers *in vitro*. In addition to express stem cell markers of *OCT4*, *NANOG* and *SOX2*, hAFSCs also express germ cell markers such as *DAZL*, *SCP3* and *STELLA*. To generate OLCs, hAFSCs in early stage of passages were cultured in conditional media supplemented with 5% FBS and 5% porcine follicle fluid for 10-15 days. Cell aggregates were derived from hAFSCs, some of aggregates showed the structures that were morphologically similar to the primordial follicle, in which the estradiol production and the expression of steroidogenic enzymes had been proved. The cumulus-oocyte-complexes (COCs) structures were then ovulated from the aggregates, and the OLCs released from COCs were also observed. OLCs were in different sizes (range from 50-120 μm) with the thin and fragile zona pellucida, some of OLCs attached the surface of culture plate and some floating in the media. The folliculogenesis and oogenesis associated markers, including OCT4, VASA, FIGLA, IFTM3, DAZL, BMP15, GDF9, IFTM3, SCP3 and zona pellucida glycoproteins, were activated in both follicle-like structures and OLCs. Culturing OLCs in oocyte growth medium for another 5-10

days, some OLCs developed spontaneously into multi-cell structures similar to preimplantation embryos, which showed high cytoplasmic-to-nuclear ratio. Although the embryos were fragile, the embryo could be manipulated by the micropipette, suggesting that OLCs could be parthenogenetically activated at current culture condition, while the blastocyst-like structures were not discovered yet. In conclusion, hAFSCs retain the germ cell markers and can be transformed into OLCs in a short term (less then 20 days) and high efficiency *in vitro*. This study may provide a new desirable model for study germ cell formation due to wide range of sources and non-tumorigenicity.

COL2.3GFP MARKED HUMAN PLURIPOTENT STEM CELLS DEMONSTRATE OSTEOBLAST SPECIFIC REPORTER EXPRESSION IN A MOUSE CALVARIAL DEFECT MODEL

Xiaonan Xin, Xi Jiang, Liping Wang, Mary Louise Stover, Shuning Zhan, Jiangping Huang, Liisa Kuhn, I-Ping Chen, Ernst Reichenberger, David Rowe, Alexander Lichtler
Reconstructive Sciences, University of Connecticut Health Center, Farmington, CT, United States

The use of hESC and induced pluripotent stem cells (iPSC) for study and treatment of genetic bone diseases, such as craniometaphyseal dysplasia (CMD) and osteogenesis imperfecta (OI), or bone injuries requires protocols to differentiate hESC/iPSC into cells with osteogenic potential. We have established zinc finger nuclease (ZFN) technology to increase the efficiency of homologous recombination at AAVS1 site, and have delivered a construct containing Col2.3 promoter driven GFPemerald to human embryonic stem cells (H9Zn2.3GFP), and Col2.3RFP to iPSC, to mark the cells in the osteoblast lineage. The targeted cells had a normal karyotype, and we demonstrated the pluripotency of a clonal line by Tra1-60 immunostaining, pluripotent low density RT PCR array and embryoid body (EB) formation. In a teratoma formed using H9Zn2.3GFP cells, we identified GFP positive osteoblasts and osteocytes. We observed GFP positive cells associated with alizarin complexone (AC) labeled newly formed bone surfaces. The GFP positive cells on the bone surface were also alkaline phosphatase (AP) positive, and we also saw GFP positive cells that were encased in the bone matrix, with the appearance of osteocytes. Immunohistochemistry with human specific bone sialoprotein (BSP) antibody has indicated that the GFP positive cells are also associated with human BSP containing matrix. This bone showed a distinctive pattern of AC labeling and bone structure, which was different from mouse bone. Therefore, we believe that our Col2.3GFP marks late stage osteoblast lineage cells. We have also obtained osteoblast specific expression using iPS cells targeted with Col2.3RFP. With these cell tools, we have tested two in vitro differentiation protocols. Following a published protocol (Boyd, et. at.), we cultured Col2.3GFP or RFP labeled hESC or iPSC as a monolayer in EGM media (EGM2MV with supplements, Lonza). The differentiated cells were implanted in mouse calvarial defects, where they produced relatively abundant new bone of human cell origin, as demonstrated by the same criteria used for the teratoma bone. This bone was formed without a cartilage intermediate, similar to membranous bone. We have also established a modified protocol, which was initiated by forming embryonic bodies (EBs). Mesenchymal cells were allowed to migrate out and proliferate from the EBs in EGM media. Using the cells derived from this EB differentiation protocol in the mouse calvarial defect model, we initially observed human chondrocytes, forming an extensive cartilage matrix, which were followed by human bone matrix formation. This is similar to endochondral bone formation. We expect that our cells with the Col2.3GFP or RFP reporter will be useful to develop optimized osteogenic differentiation protocols, and to isolate osteoblasts from normal and diseased iPSC for analysis.

GENE EXPRESSION-BASED ENRICHMENT OF HUMAN ADIPOSE-DERIVED STEM CELLS FOR ENHANCED OSTEOGENIC DIFFERENTIATION

Hetal V. Desai, Eric M. Darling
Molecular Pharmacology, Physiology, and Biotechnology, Brown University, Providence, RI, United States

Introduction:

Human adipose-derived stem/stromal cells (ASCs) are an attractive source for cell-based therapies because of their lack of immunogenicity and applicability to musculoskeletal regeneration. However, ASCs display a heterogeneous response to stimuli during induction, which results in lower rates of differentiation. More homogeneous subpopulations of ASCs, however, may be predisposed to particular lineages. Isolating these subpopulations based on gene expression may provide an optimized cell source for regenerating specific tissues, and would greatly maximize cell yields while minimizing time in vitro.
The objective of this study was to isolate ASCs that are highly responsive to osteogenic induction factors based on expression of alkaline phosphatase (ALPL) mRNA, and to differentiate these cells in an effort to optimize osteogenesis.
Methods:
Expression of ALPL mRNA was detected in living cells using a DNA-based molecular beacon (MB), which yields a fluorescent signal upon binding its target mRNA. ASCs from the subcutaneous adipose tissue of seven healthy donors were obtained from Zen-Bio, Inc. and were passaged 4 times prior to use. ASCs were seeded in monolayer at a density of 25,000 cells/cm2. Cells were given osteogenic induction medium (OIM) containing lineage-specific growth factors. Four days into induction, the cells were treated with a custom-designed ALPL-specific MB via electroporation and subsequently sorted using FACS into positive (ALPL+) and negative (ALPL-) signal groups. A subset of beacon-treated cells from the same initial population was left unsorted.
Unsorted, ALPL+, and ALPL- cells were seeded in 96-well plates at 8,000 cells/well and given OIM. Following seven days of induction, four of the sample wells were lysed and assessed for units of alkaline phosphatase (ALP) protein activity (U). After 21 days of induction, the remaining four wells were fixed and stained with Alizarin Red-S (ARS), a charged dye which binds calcified matrix characteristic of bone formation. After staining, the dye was eluted and the absorbance (A) of the dye was measured at 540nm. The activity and absorbance measurements were normalized on a per cell basis (U/cell, A/cell).
Results and Conclusions:
Enhanced osteogenic differentiation existed in ALPL+ cells compared to either unsorted and ALPL- cells, resulting in significant increases in ALPL protein activity and deposition of calcified matrix.
ALPL+ cells had 1.4 times more ALP activity than unsorted cells (700 U/cell vs. 500 U/cell, $p<0.05$) and 14 times more activity than ALPL- cells (50 U/cell, $p<0.01$). Even more remarkably, ALPL+ cells displayed a two-fold increase in calcified matrix deposition over unsorted ASCs (A/cell=0.133±0.022 vs. 0.040±0.007, $p<0.01$) and a four-fold increase over ALPL- cells (A/cell=0.026±0.009, $p<0.01$).
Results indicated that sorting ASCs based on expression of ALPL yields subpopulations that are primed to undergo osteogenesis. Interestingly, though ASC populations contained only 10-15% ALPL- cells prior to sorting, removal of these unresponsive cells yielded disproportionately significant increases in osteogenic metabolite production. Pilot studies have shown similar trends for ASCs undergoing adipogenic differentiation when sorted using target genes such as lipoprotein lipase. Our reported findings show the utility of using FACS with MBs to obtain highly responsive cells for bone formation and could potentially be applied to other lineages.

SUPPRESSION OF POLYAMINE BIOSYNTHESIS PROMOTE OSTEOGENIC DIFFERENTIATION OF HUMAN BONE MARROW-DERIVED MESENCHYMAL STEM CELLS

Mon-Juan Lee, Yo-Hsian Tsai, Kuan-Lian Lin
Department of Bioscience Technology, Chang Jung Christian University, Tainan, Taiwan

Polyamines are naturally occurring organic polycations that are ubiquitous in all organisms, and are essential for cell proliferation and differentiation. Although polyamines are involved in various cellular processes, their roles in stem cell differentiation are relatively unexplored. Results from our previous studies suggest that exogenous polyamines, including putrescine, spermidine, and spermine, were capable of promoting osteogenic differentiation of human bone marrow-derived mesenchymal stem cells (hBMSCs). To investigate the mechanism underlying the osteogenic potential of polyamines and the crosstalk between pathways of osteogenesis and polyamine metabolism, we treated hBMSCs with α-difluoromethylornithine (DFMO), the irreversible inhibitor of the polyamine biosynthetic

enzyme, ornithine decarboxylase (ODC), to determine whether suppression of intracellular polyamine level affects the differentiation fate of hBMSCs. Our results indicate that DFMO up-regulated alkaline phosphatase (ALP) activity, and enhanced the mRNA expression of osteogenic genes such as Runt-related transcription factor 2 (Runx2), ALP, osteocalcin and osteopontin. In addition, extracellular matrix mineralization, a marker for osteoblast maturation, was accelerated in the presence of DFMO. We then suppressed the gene expression of ODC in hBMSCs using small interfering RNAs (siRNAs) designed against ODC (siODC), and found that the mRNA level of osteogenic genes such as osteocalcin and osteopontin were increased. These results suggest that suppression of polyamine biosynthesis may be correlated with the induction of osteogenic differentiation, and the level of intracellular polyamines may be manipulated to promote osteogenic differentiation. Currently, the only drug approved by the U.S. Food and Drug Administration (FDA) to stimulate bone formation is parathyroid hormone (PTH), which possesses the risk of inducing osteosarcoma. Studies on DFMO, a chemopreventive agent for cancer that is being evaluated in clinical trials, as novel osteogenic inducer not only help to elucidate the role of polyamine metabolism in the lineage commitment of stem cells, but also promote the development of polyamine-derived new drugs that stimulate bone formation.

MULTIPOTENT PERIVASCULAR MESENCHYMAL STEM CELLS IN THE HUMAN BRAIN

Ilknur Ozen[1], Nicolaj Christophersen Christophersen[2], Thomas Reinbothe[3], Edward Visse[4], Patrik Brundin[2], Gesine Paul[5]

[A]Department of Clinical Science,Translational Neurology, [B]Department of Experimental Medical Science, Neuronal Survival Unit, [C]Diabetes Centre, Scania University Hospital Malmö, [D]Department of Clinical Science, The Rausing laboratory, [E]Department of Clinical Science, Translational Neurology, [1]Lund University, Lund, Sweden

Key questions in adult stem cell biology revolve around origin and physiological role of adult stem cell populations. Mesenchymal stem cells have remained elusive with regard to their *in vivo* physiology. Recent observations suggest that almost all adult tissues contain mesenchymal-like progenitors in the perivascular niche. These cells can differentiate into mesodermal cell types and may even be endowed with tissue-specific differentiation capacities. We have isolated and characterized a previously unrecognized progenitor cell population in the adult human brain. This cell population exhibits characteristics of both mesenchymal stem cells and pericytes *in vitro* (CD73, CD90, CD13, CD106, CD49d, PDGFR-, RGS5, -SMA, NG2) but in its native state does not express hematopoietic (CD34, CD45), endothelial (CD31), microglial (CD14, CD11b), glial (GFAP, O4), and neuronal progenitor markers (CD133, SOX1, NGN2, PAX6 and Musashi). We demonstrate, at a clonal level, that the progenitors have true multilineage potential not only towards a mesodermal but also neuroectodermal phenotype and can differentiate into neurons. Thus, the vasculature in the adult human brain contains progenitor cells with multilineage capacity that may represent a reservoir that can be exploited in attempts to repair the damaged or diseased brain.

PERIODONTAL LIGAMENT DERIVED STEM CELLS EXHIBIT THE CAPACITY FOR LONG TERM SURVIVAL AND GENERATION OF MULTIPLE TISSUE TYPES IN VIVO

Danijela Menicanin[1], Krzysztof M. Mrozik[2], Victor Marino[2], Mark P. Bartold[2], Stan Gronthos[3]

[A]Dentistry, [B]CACDRC, Dentistry, [C]School of Medical Sciences, [1]University of Adelaide, Adelaide, Australia

Characterisation of progenitor cells residing in the periodontal ligament has demonstrated that these cells exhibit similar features to that described for bone marrow stromal cells (BMSCs) yet display specific distinguishing properties. Due to the developmental potential demonstrated by periodontal ligament stem cells (PDLSC), they are currently considered a favourable candidate for stem cell based tissue engineering applications for treatment of periodontal disease.

In this study we assessed the developmental capacity of ovine derived PDLSCs using an *in vivo* ectopic bone formation assay. BrdU labelled PDLSCs were subcutaneously transplanted into the dorsal surface of eight-week-old immunocompromised (NOD/SCID) mice. Concurrent with histological assessment of recovered PDLSC explants, progenitor populations were isolated and re-established from primary transplants, characterized *in vitro* and re-implanted into the NOD/SCID mice.
Our findings demonstrate the capacity of ovine derived PDLSC to survive, proliferate and generate multiple tissue types *in vivo*, including mineralised structures, fibrous tissue and vasculature. Furthermore, their ability to generate secondary structures highlights their potential for self-renewal and long-term contribution to tissue regeneration.
This study, characterising the growth and developmental properties of PDLSCs, contributes to the current body of knowledge and highlights the potential clinical use of these cells in tissue regeneration.

REGENERATIVE CAPACITY OF OLD MUSCLE STEM CELLS DECLINES WITHOUT SIGNIFICANT ACCUMULATION OF DNA DAMAGE

Wendy Cousin, Michelle L. Ho, Rajiv Desai, Andrea Tham, Robert Y. Chen, Christian Elabd, Irina M. Conboy
Bioengineering, University of California, Berkeley, Berkeley, CA, United States

The performance of adult stem cells is crucial for tissue homeostasis but their regenerative capacity declines with age, leading to failure of multiple organs. In skeletal muscle this failure is manifested by the loss of functional tissue, the accumulation of fibrosis, and a reduced satellite-cell-mediated myogenesis in response to injury. While recent studies have shown that changes in the composition of the satellite cell niche are at least in part responsible for the impaired function observed with aging, little is known about the effects of aging on the intrinsic properties of satellite cells. For instance, their ability to repair DNA damage and the effects of a potential accumulation of DNA double strand breaks (DSBs) on their regenerative performance remain unclear.
This work demonstrates that there is no significant accumulation of innate DNA DSBs in muscle stem cells with age as assayed after cell isolation and in tissue sections. Moreover upon muscle injury, old satellite cells – known to have an impaired regenerative response – did not show any difference in the number of DNA DSBs at multiple time points after injury, in the expression of key DNA DSB repair proteins and DNA damage response genes, and in their radiosensitivity. Additionally, there is no significant difference in the expression of globally assayed DNA damage response genes, suggesting that not only DSBs, but also other types of DNA damage do not significantly mark aged muscle stem cells.
Interestingly, muscle stem cells from DNA-DSB-deficient SCID mice were as capable as those of young wild type mice to regenerate muscle *in vivo* and to form myogenic colonies *in vitro* despite an accumulation of DNA damage and a pronounced radiosensitivity, thereby suggesting that the inability to repair DNA DSBs does not directly correlate with the ability to regenerate muscle after injury.
Overall, our findings suggest that a DNA DSB repair deficiency is unlikely to be a major contributor to the decline in muscle regeneration observed upon aging.

W-3112

REVERSING THE AGING OF MUSCLE STEM CELLS BY SUPPLEMENTING GROWTH DIFFERENTIATION FACTOR-11.

Manisha Sinha[1], Juhyun Oh[1], Christine Miller[1], Samuel Regalado[1], Francesco Loffredo[2], Richard T. Lee[2], Amy J. Wagers[1]
[1]Stem Cell & Regenerative Biology, Harvard University, Cambridge, MA, United States, [2]Brigham and Women's Hospital, Cambridge, MA, United States

Aging is associated with a degenerative loss of skeletal muscle mass, strength, function and regenerative capacity after injury. Age-associated muscle wasting, weakness and slow recovery from injury profoundly impact health and

quality of life in the elderly human population. Skeletal muscle growth and regeneration after injury depend on a rare population of muscle fiber-associated mononuclear cells called satellite cells, which reside beneath the basal lamina and adjacent to the sarcolemma of myofibers. The precise molecular mechanisms that underlie age-related declines in muscle regeneration remain unclear, though several lines of evidence indicate both intrinsic cellular properties and extrinsic signaling factors as being responsible.
Amongst intrinsic properties, our data suggest that deficient muscle regeneration in old age results from a progressive decline in the overall frequency and function of satellite cells - the muscle-forming stem cells. Our work also implicates compromised genomic integrity in these cells as a potential mechanism by which age-dependent muscle dysfunction arises. Similar to other tissue-resident stem cells, age dependent compromise in DNA integrity in muscle stem cells may arise due to their quiescent nature under normal physiological conditions and their exposure to age-associated increases in oxidative and inflammatory stress, generated as by-products of normal muscle metabolism and local injury.
Importantly however, our data indicate that such age-related defects in muscle stem cell genomic integrity and myogenic activity may be reversible, and controlled at least in part by age-regulated systemic factors. The effect of cell-extrinsic systemic factors on reversing age-associated functional decline in adult stem and progenitor cells has been demonstrated in studies of the skeletal muscle and central nervous system after heterochronic parabiosis, a surgical intervention in which one old and one young mouse are joined and develop a shared blood circulation. From these studies, several soluble molecules, including members of the TGFb and Wnt super-family pathways, have emerged as “aging” factors that impede muscle regeneration.
In this study, we analyze the pro-myogenic effects of a youthful circulation and show that supplementing a systemic factor, Growth Differentiation Factor (GDF-11), in the circulation of aged mice can reverse the age-related impairment of muscle stem cell genomic integrity, myogenic function and regenerative capacity. Our data uncover a crucial mechanism of systemic rejuvenation of tissue stem cell function and identify a promising therapeutic candidate to encourage the maintenance and regeneration of aged skeletal muscle.

IMMORTALIZED PATIENT MYOGENIC STEM CELLS RECAPITULATE PATHOGENESIS IN HUMAN CONGENITAL MUSCULAR DYSTROPHY DUE TO LAMININ-ALPHA2-DEFICIENCY.

SOONSANG YOON[1], GUIDO STADLER[2], WOODRING E. WRIGHT[2], JEFFREY B. MILLER[1]
[1]Department of Neurology and Physiology & Biophysics, Boston University School of Medicine, Boston, MA, United States, [2]Department of Cell Biology, University of Texas Southwestern Medical Center, Dallas, TX, United States

BACKGROUND. Congenital muscular dystrophy Type 1A (MDC1A) is a severe, recessive disease of childhood onset that is caused by mutation of the LAMA2 gene encoding laminin-alpha2. Studies with both mouse models and primary cultures of myogenic cells obtained from human MDC1A patients suggest that aberrant activation of cell death is a significant contributor to pathogenesis in laminin-alpha2-deficiency. Use of primary cultures to study MDC1A is constrained, however, both by the small number of available myogenic cell strains and the limited replication capacity of the primary cells.
OBJECTIVE AND METHODS. To determine if immortalized MDC1A myogenic cells would recapitulate the pathological changes seen in primary MDC1A cultures, we generated immortalized, clonal lines of human MDC1A and normal myogenic stem cells via overexpression of both CDK4 and the telomerase catalytic component (human telomerase reverse transcriptase; hTERT) using methods described previously (Stadler et al. 2011. Skelet Muscle. 1:12). We then compared proliferation, differentiation, and caspase-3 activation (as a marker of pathology) in cultures of immortalized MDC1A and normal vs. primary MDC1A and normal myogenic cells.
RESULTS. When cultured at low density in high serum growth medium, the immortalized MDC1A and normal myogenic cells maintained proliferation for >150 population doublings, whereas primary cultures ceased proliferating at 50 - 60 population doublings. In addition, at all population doublings tested, the immortalized MDC1A and healthy lines retained the capacity to fuse to form multinucleate myotubes and express muscle-specific genes when switched to low serum medium. Furthermore, activation of caspase-3, as assessed by immunostaining and en-

zymatic activity, was several-fold higher in the myotubes formed from immortalized MDC1A myoblasts compared to myotubes formed from immortalized control myoblasts. Upon treatment with staurosporine, caspase-3 activity was increased to a higher level in immortalized MDC1A than in control myogenic cells and Ku70 acetylation was also increased. This pattern of aberrantly increased caspase-3 activation in myotubes formed from immortalized MDC1A myogenic cells, was similar to that found previously in myotubes formed from primary MDC1A myogenic cells.
CONCLUSION. Immortalized MDC1A myogenic cells provide a new resource for studies of pathogenetic mechanisms and possible therapeutic approaches in laminin-alpha2-deficiency.

W-3114

MODULATING CELL CYCLE INHIBITORS TO CONTROL PROGENITOR CELL FATE DECISIONS

Pratiksha I. Thakore, David G. Ousterout, Charles A. Gersbach
Department of Biomedical Engineering, Duke University, Durham, NC, United States

A key step in the transition from a progenitor to a differentiated cell type is exit from the cell cycle. In mammals, most progenitor cells irreversibly lose proliferative capacity upon terminal differentiation. Cell cycle inhibitors, including cyclin-dependent kinase inhibitor (CKI) p21, retinoblastoma protein, and INK4a CKIs, orchestrate cell cycle exit and play a role in cessation of proliferation. These cell cycle inhibitors can thus be targeted to control whether cells remain progenitors or terminally differentiate. We hypothesized that reduced expression of p21 in a myoblast model would help the cells maintain a progenitor phenotype with increased regenerative potential by inhibiting differentiation and increasing self-renewal capacity. The CKI p21 is an ideal target for silencing because of a reduced risk of oncogenic side effects, compared to knockdown of tumor suppressors Rb and INK4. Also, the enhanced regeneration observed in MRL/MpJ mice and other “superhealer” strains is characterized by modified cell cycle activity and can be recapitulated in a p21 knockout mouse model. Using a lentiviral vector expressing short hairpin RNA (shRNA) against p21, we achieved over 85% knockdown of p21 expression in primary mouse myoblasts by quantitative PCR and western blot. In differentiation conditions, myoblast fusion into myotubes was dramatically reduced in p21 shRNA-expressing (p21sh) cells relative to non-treated and non-specific shRNA-treated controls. However, myogenic differentiation was not completely inhibited: p21 shRNA-expressing myoblasts showed similar upregulation of myogenic markers myogenin, troponin T, and desmin as non-treated and non-specific shRNA-treated cells after 3 days in differentiation conditions. This suggests that silencing p21 does not disrupt commitment to the myoblast lineage. Additionally, in a mixed population of p21sh and non-treated myoblasts, the p21sh cells are enriched 9-fold over 20 days in low serum culture. Silencing p21 allows progenitors cells to remain proliferative even in the absence of growth signals. This was further corroborated in BrdU-labeling studies, which indicated that a significantly higher percentage of p21sh myoblasts remain active in the cell cycle by progressing to S phase in low serum culture conditions. We have demonstrated that p21 expression can be controlled to effectively maintain a progenitor cell phenotype by delaying differentiation and preserving growth capacity. Furthermore, we have shown that modifying cell cycle inhibitors can increase the regenerative potential of these progenitor cells. When myoblasts were delivered to the tibialis anterior muscles of mice concurrently with cardiotoxin-induced injury, cells expressing p21 shRNA showed greater engraftment efficiency and fusion with the host muscle, compared both to non-treated and non-specific shRNA treated controls. Cell cycle inhibitors regulate terminal differentiation in a variety of cell types, and these findings demonstrate that modulating cell cycle inhibitor expression can be used to guide progenitor cell fate decisions. Preserving the regenerative capacity of progenitor cells can increase the efficacy of cellular therapies, in which expansion of donor stem cell populations without compromising proliferative potential or the progenitor phenotype is necessary.

HUMAN ADIPOSE-DERIVED MESENCHYMAL STROMAL STEM-CELLS INJECTIONS IN GOLDEN RETRIEVER MUSCULAR DYSTROPHY (GRMD) DOGS: A FOUR-YEAR FOLLOW-UP

Mayana Zatz, Natassia M. Vieira, Mariane Secco, Eder Zucconi, Marcos Valadares, Carlos R. Bueno Junior, Mariz Vainzof, Mayra Pelatti, Juliana Gomes, Amanda Assoni, Thais Andrade, Vivian Landini
University of Sao Paulo, São Paulo, Brazil

Duchenne muscular dystrophy (DMD), a lethal X-linked disorder, is the most common and severe form of muscular dystrophies, affecting 1 in 3500 male births. Mutations in the DMD gene which result in the absence of muscle dystrophin are associated to a progressive and rapid degeneration of skeletal muscle. Affected patients are wheelchair-bound around age 10-12 and dependent for all activities before age 20. The possibility to treat DMD through cell therapy has been widely investigated. However before starting clinical trials in humans many questions still need to be addressed in pre-clinical studies. In addition to clarifying the role of the exogenous cells in the dystrophic muscle, one important concern is whether there is an increased risk of tumors or any other long-term side effects following stem-cells injections. Since mice models have a short life span, the best animal model to address questions related to the safety of the procedure is the Golden Retriever Muscular Dystrophy (GRMD) dog, which reproduces the full spectrum of human DMD. Affected animals carry a mutation that predicts a premature termination codon in exon 8 and a peptide that is 5% the size of normal dystrophin. These dogs present clinical signs within the first weeks of life and most of them do not survive beyond age two. We have injected human adipose-derived stromal cells (hASCs), from two different donors, in three GRMD dogs, without immunosuppression. Each animal was injected in the cephalic vein with 5X107 cells/kg within their first year of life: weekly in the first month and then monthly. Two of them (Dolar and Yuan) will be five years old in September and Rum is currently 1.6 years-old (born in july/2011). In Dolar and Yuan, who received cells from donor 1, we observed that hASCs injected systemically were able to reach, engraft, and express human dystrophin in the host GRMD dystrophic muscle up to 6 months after transplantation. When cells from donor 2 were injected in Rum, no human dystrophin was found in the host muscle but the three dogs showed clinical improvement during and right after the last hASCS injections with an apparent stabilization afterwards. Most importantly, after almost four years of follow-up for Dolar and Yuan there was no tumor or other side effect suggesting that hASCS transplantation is a safe procedure, which may have important applications for future therapy in patients with different forms of muscular dystrophies. Supported by FAPESP-CEPID,INCT-CNPq, ABDIM and the Duchenne research fund.

EXPLORING THE MULTIPOTENT NATURE OF DEDIFFERENTIATED MUSCLE CELLS

Kinga Vojnits[1], Xiaodong Mu[2], Wei Xu[2], Yinda Tang[2], Haiying Pan[1], Yohan Choi[1], Yong Li[1]
[1]Pediatric Surgery, The Center for Stem Cell and Regenerative Medicine, The Brown Foundation Institute of Molecular Medicine (IMM) at the University of Texas Health Science Center at Houston, Houston, TX, United States, [2]The Laboratory of Molecular Pathology, Stem Cell Research Center, Childrens Hospital of UPMC, Pittsburgh, PA, United States

One of the striking phenomena in wildlife is the regrowth of damaged or wounded tissues. Unfortunately, mammals including humans have limited capacity for regeneration unlike several non-mammalian species, e.g. amphibians or zebrafish that can even replace complete limbs or renew their lost tissues. Similar evidences have also been discovered in the mammals, e.g. amputated digit tips of humans and mice can fully regenerate at early stages of development. The key feature in these processes is believed the dedifferentiation of mature cells into a more primitive, multipotent state. Here, we report the multipotent potential of injury-induced dedifferentiated mouse muscle cells, developed by our previously published cre/lox-β-galactoside system, which can be simply induced to neurosphere formation in vitro. Our results indicated these dedifferentiated cre/lox-β-galactoside positive cells formed easily and effectively neurospheres, floating in suspension, while the control primary myoblasts showed no sign forming these structures. Moreover, we present for the first time that the induced neurospheres expressed representative markers of all the three germ layers (such as Nestin, Ncam1, Brachyury, and Afp), indicating their heterogeneity as containing various cell types. After replacing these neurospheres into monolayer culture, their myogenic ability/memory recovered and formed myotube-like structures, highly expressing myogenic proteins (e.g. Myogenin and MyoD) and barely other lineage specific markers. Additionally, the neurospheres differentiated into the three major neural lineages (neurons, astrocytes, and oligodendrocytes) as they expressed Mtap2, β-Tubulin III, Gfap, Nestin and Olig1/2 on protein and gene level once cultured in a neural differentiation media. These findings suggest that dedifferentiated mammalian muscle cells are sensitive to environmental stimulation, having multipotent status, and can overcome germ lineage restrictions. Further work is needed to elucidate their survival, proliferation, migration and neuronal/myogenic differentiation capacity in vivo to prove their benefits in application of regenerative medicine for neural-muscle related injuries and diseases.

W-3117

EFFICIENT DERIVATION AND FACS PURIFICATION OF HYPAXIAL MUSCLE PRECURSORS FROM HUMAN PLURIPOTENT STEM CELLS

Bianca Borchin, Joseph Chen, **Tiziano Barberi**
Australian Regenerative Medicine Institute, Monash University, Clayton, Australia

Due to their intrinsic developmental potential, human pluripotent stem cells (hPSCs) provide an invaluable source of cells that could be used in regenerative medicine as well as an in vitro model to study early human development. Although significant advancements to the directed differentiation into specific neural (CNS, neural crest), endoderm (liver, pancreas) and lateral mesoderm (blood, endothelium) fates have been made, little has been attained on the derivation of skeletal muscle from hPSCs. Current protocols are inefficient or rely on transgene expression of specific myogenic factors to obtain the desired cells. Moreover, purification of early hPSC-derived muscle precursors has not been achieved.
With the aim of filling this gap, we set up a new method to specifically induce hPSCs to differentiate towards skeletal muscle in a monolayer feeder-free culture system. This highly efficient protocol has been based on a small molecule treatment of hPSCs for 4 days to promote skeletal muscle development, followed by a single growth factor treatment (10 days) for the expansion of the myogenic cells.
Starting at around day 20 of differentiation, in treated hPSCs, a population of Pax3+ muscle precursors started to be detected in the differentiating cultures and their number increased dramatically over the next 10 days. In contrast, this population was almost absent in differentiating untreated hPSCs. These Pax3+ cells after a few additional days started to co-express Pax7, another important muscle specifier gene, confirming their myogenic identity. In addition, we also detected on these cells the expression of Lbx-1, a homeobox transcription factors that marks migratory hypaxial muscle cells in the embryo. Importantly, we were able to purify by FACS the emerging Pax3+ as well Pax3+/Pax7+ precursors, using a combination of surface markers that included the chemokine receptor CXCR4. When replated, the sorted cells readily differentiated into myogenin+ myocytes or, under specific growth factor treatment, could have been expanded in culture and maintained undifferentiated for at least two additional weeks.
At around day 30-35 of differentiation, bipolar myocytes also started to be observed in the culture dishes of treated hPSC, with their number increasing over time. Thus, using another FACS strategy we were also able to purify directly these mature myocytes based on their expression of the Acetylcholin receptor (AchR). This additional strategy will enable investigators for a quick purification of hPSC-derived myocytes that could be immediately used for new drug and toxicity screenings.
Furthermore, we tested the ability of FACS purified muscle precursors to integrate in a host muscle upon transplantation of GFP-labeled cells in the limb buds of day 3.5 chick embryos. As expected, grafted cells started to migrate and differentiate along the host forming limbs.
This new differentiation protocol has been validated on several hPSC lines (ESC and iPS cells), including one derived from a muscular dystrophy patient.

The developmental progression from undifferentiated PSC toward the specification of muscle cells is largely unexplored in humans. The generation of myogenic precursors from normal and patient derived hPSCs, not only will give new insights into human skeletal muscle development and disease, but will also accelerate the move towards the use of hPSC-derived muscle cells for therapeutic use in a variety of muscle atrophy and wasting conditions.

W-3118

IN VITRO EXPANSION OF MOUSE SATELLITE CELLS FOR CELL THERAPY OF DUCHENNE MUSCULAR DYSTROPHY

Mohammadsharif Tabebordbar[1], Cong Xu[2], Leonard Zon[2], Amy Wagers[1]
[1]Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States, [2]Division of Hematology/ Oncology, Harvard Medical School, Children's hospital Boston, Boston, MA, United States

Duchenne Muscular Dystrophy (DMD) is a progressive muscle wasting disease caused by mutations in the *DYSTROPHIN* gene. Replacement of muscle stem cells (i.e., satellite cells) presents a promising therapeutic approach for restoring *DYSTROPHIN* expression to muscle fibers in these patients; however the low frequency of satellite cells in adult muscle is an obstacle for isolating sufficient number of cells for engraftment. To address this issue, we have sought culture conditions that would support the *ex-vivo* expansion of satellite cells and potentially provide more cells for transplantation. In this study, we screened 2,400 chemicals using a zebrafish blastomere culture system in order to find potentially conserved enhancers of muscle progenitor proliferation. Out of 6 chemicals that activated myogenesis in the zebrafish system, forskolin, an adenylyl cyclase activator, also dramatically expanded mouse satellite cells in culture. Forskolin treatment did not affect satellite cell survival, but did increase satellite cell proliferation by elevating cyclic adenosine monophosphate (cAMP) levels. Forskolin-treated cultured cells retained the immunophenotypic characteristics of engraftable satellite cells, and transplantation of compound-treated cells into dystrophic muscle yielded a significantly higher level of engraftment compared to control cells. Expansion of muscle satellite cells in culture using small molecule-based approaches such as that described here provides the possibility of improving cell replacement therapies for neuromuscular disorders.

ENHANCED IN VIVO REGENERATIVE POTENTIAL OF FETAL MUSCLE STEM CELLS

Matthew Tierney, Francesca Boscolo, Alessandra Sacco
Sanford-Burnham Medical Research Institute, La Jolla, CA, United States

Adult muscle stem cells (MuSC) are required for the repair and homeostatic maintenance of skeletal muscle, residing in a quiescent state until stimulated by external cues to regenerate damaged tissues. Their developmental precursors, fetal MuSC, are an actively cycling population of Pax3/Pax7-expressing cells required for embryonic myogenesis and represent a related but intrinsically different cell population. To assess these cells functionally, we compared their self-renewal and regenerative potential with adult MuSC. Both populations were successfully isolated via flow cytometry using the cell surface markers alpha-7 integrin and CD34, uniformly expressed the paired box transcription factor Pax7 and were readily able to undergo terminal myogenic differentiation and form multinucleated myotubes in vitro. Interestingly, a subset of cycling fetal MuSC did not upregulate MyoD during in vitro expansion, suggesting that they are resistant to myogenic commitment. Cytokine exposure in vitro revealed that those uncommitted fetal MuSC may be preferentially sensitive to the potent mitogen FGF2, while also less responsive to Wnt/β-catenin signaling known to promote terminal differentiation. When transplanted in vivo intramuscularly, fetal MuSC displayed a robust proliferative potential and successfully fused with a significantly higher number of resident myofibers than adult MuSC. Following engraftment, fetal MuSC were able to give rise to an expanded pool of progenitors following serial injury and also retain their regenerative potential following serial transplantation, demonstrating long-term self-renewal capacity. Finally, we observed that the progressive entry of Pax7+ MuSC into the satellite cell niche is associated with reduced proliferation, suggesting that the changing microenvironment during developmental myogenesis plays a critical role in MuSC function. Our current work continues to utilize comparative studies aimed at uncovering the molecular pathways responsible for governing fetal MuSC regenerative

behavior. In addition, we are pursuing the use of genetic models to dynamically study clonal patterning and fate mapping of MuSC to improve our understanding of the factors governing MuSC behavioral changes during development.

ENGINEERING A WNT7A-BASED PROTEIN THERAPEUTIC FOR THE TREATMENT OF MUSCULAR DYSTROPHY

Monica H. Bennett[1], Tom Lee[1], Kevin Lai[1], Michael Fitch[1], Christina Lynch[1], Michael Rudnicki[2], Peter Flynn[1]
[1]Fate Therapeutics, San Diego, CA, United States, [2]Department of Medicine, University of Ottawa, Ottawa, ON, Canada

In healthy skeletal muscle, satellite stem cells are the key regenerative precursors: normally quiescent but becoming activated, proliferating and differentiating into myoblasts for either de novo fiber formation or as the source of increased nuclear content for existing fibers in response to tissue damage. A core pathophysiologic phenomenon seen in muscular dystrophy is a cycle of muscle degeneration leading to continuous compensatory satellite cell activation and differentiation to affect a regenerative response. It is clear that the regeneration cannot keep pace, and tissue degeneration results in ultimate loss of function. Identifying and enhancing the underlying molecular and cellular mechanisms of the natural tissue repair process by restoring the balance of quiescent and activated stem cells thus represents a promising approach to therapeutic intervention, irrespective of etiology. WNT7a has previously been established as a potent mediator of muscle regeneration through a combination of satellite stem cell symmetrical expansion and direct myofiber hypertrophic activity. In recent data, wild-type WNT7a protein treatment has been shown to confer significant functional improvement in rodent models of muscular dystrophy. Wnt proteins are developmental morphogens that drive embryogenesis, stem cell fate determination and cellular proliferation and differentiation in a tissue/cell-specific manner. Wnt proteins have not previously been developed as therapeutics primarily due to challenges in protein manufacture and formulation at scale. Building on the academic observations of WNT7a activity, we have used rational protein design and structural engineering to produce a panel of WNT7a analogs with preferred pharmaceutical, manufacturing and formulation properties. These WNT7a analogs induced significant myotube hypertrophy in vitro using murine, human DMD, BMD and FSHD primary myoblast culture systems. The direct administration of the pharmaceutical candidate WNT7a proteins to the tibialis anterior (TA) muscle of either wild-type or dystrophic (MDX) mice resulted in significant satellite stem cell expansion and fiber hypertrophy. In histological assessments, treatment with the engineered WNT7a protein forms significantly reduced inflammation and muscle fiber necrosis in the MDX mouse. Further, in situ measurements demonstrated significant increases in specific force and twitch force on WNT7a-analog administration to the MDX TA muscle. Together, these results suggest the therapeutic potential for WNT7a and demonstrate a clear path to drug candidate development.

PHENOTYPIC REVERSAL OF LONG QT SYNDROME 2 IN PATIENT-SPECIFIC HUMAN PLURIPOTENT STEM CELL DERIVED CARDIOMYOYCTES

Ashish Mehta[1], Glen Lester Sequiera[1], Chrishan JA Ramachandra[1], Yuliansa Sudibyo[1], Yingying Chung[1], Sheng Jingwei[1], YW Wong[2], TH Tan[2], Reginald Liew[3], Philip Wong[1], Winston Shim[1]
[1]National Heart Centre Singapore, Singapore, Singapore, [2]KK Hospital, Singapore, Singapore, [3]DUKE-NUS Singapore, Singapore, Singapore

Long QT Syndrome 2 (LQTS2) caused by missense mutations in hERG channel is clinically associated with abnormally prolonged ventricular repolarization and sudden cardiac deaths. Modeling monogenic arrhythmogenic dis-

eases using induced pluripotent stem cells (iPSCs) offer unprecedented mechanistic insights into disease pathogenesis.
Aim: We evaluated if cardiomyocytes (CMs) derived from LQTS2 patient-specific (A561V mutant) hiPSC recapitulate the disease phenotype with defective trafficking of hERG channel in vitro and demonstrate phenotypic reversal through pharmacological intervention.
Methods: Electrophysiological recordings through microelectrode arrays (MEA) and patch clamp were utilized to recapitulate disease phenotype as well as I_{Kr} current recordings. Gene expression arrays and immunofluorescence were performed to demonstrate defective and corrective trafficking of hERG in LQTS2-hiPSC derived cardiomyocytes.
Results: We produced cardiomyocytes manifesting LQTS2 phenotype (A561V missense mutation in *KCNH2*) from iPSCs using virus-free reprogramming method. These cardiomyocytes recapitulate dysfunction of hERG potassium channel with 90% diminished I_{Kr} currents, 30% prolonged repolarization durations and elevated arrhythmogenesis. Further, our results demonstrated 3-fold reduction in hERG sarcolemma localization densities together with a 4-fold increase in sequestered hERG within the ER-golgi complex. This was also accompanied with significant dysregulation of folding chaperones and processing proteasome markers. These results collectively confirmed trafficking defect-induced disease manifestation. Treatment with a calpain inhibitor and atypical 26S proteasomal inhibitor significantly reduced disease manifestation by enhancing I_{Kr} currents, reducing repolarization durations and diminishing arrhythmogenesis. This pharmacological intervention also resulted in increasing sarcolemmal hERG localization densities with reduced sequestering within the ER-Golgi complex. Diverged from biophysical interference of hERG channel, our results show that modulation of chaperones and proteasomes could re-direct hERG channel to sarcolemmal membrane and reduce prolonged repolarization durations in LQTS2-CMs.
Conclusion: Understanding the molecular mechanisms governing arrhythymogenic diseases could be effectively utilized for early evaluations of candidate drugs that could be helpful in developing therapeutic regimes for LQTS2. Our study for the first time leverages the potential of reprogramming technology in disease modeling for an alternative mechanistic elucidation of rescue strategy for LQTS2 via corrective re-trafficking.

PURIFICATION OF LONG QT-SYNDROME 3 INDUCED PLURIPOTENT STEM CELL-DERIVED CARDIOMYOCYTES FOR PHARMACOLOGICAL SCREENING WITH AUTOMATED PLANAR PATCH CLAMP

Daniela Malan, Stephanie Friedrichs, Bernd K. Fleischmann, Philipp Sasse
University of Bonn, Bonn, Germany

Long QT syndrome 3 (LQTS 3) is an inherited disease due to a gain of function mutation of the cardiac sodium channel (Scn5a). This disease is characterized by a prolonged long QT interval in the ECG and patients suffer from life threatening cardiac arrhythmias and sudden cardiac death. To show that induced pluripotent stem (iPS)-cells can be used to investigate this disease in vitro, we have generated iPS cells from a LQTS 3 mouse model carrying the human ΔKPQ deletion of Scn5a. Cardiomyocytes differentiated from these LQTS3-iPS cells showed faster recovery from inactivation of sodium currents and larger late sodium currents compare to wild-type cells. Moreover action potential durations were prolonged and early afterdepolarizations occurred at low pacing frequencies in LQTS 3-specific iPS derived cardiomyocytes.
For screening of pharmacological substances using automated assays, a pure population of cardiomyocytes is required. We have therefore genetically engineered wild-type and LQTS 3 iPS cell lines with a lentivirus to expresses a puromycin-resistance gene under the control of the α-myosin heavy chain promoter. Application of puromycin to differentiated iPS cells led to death of non-cardiomyocytes and resulted in a nearly pure cardiomyocyte population (wild-type: 92.8±6.2 %, n=5, and LQTS 3: 87.7±9.7%, n=4). Purified LQTS 3-specific cardiomyocytes showed also prolonged action potential durations and early afterdepolarizations at low pacing rates. Furthermore the Na+ channel blocker mexitilene showed a reduction of action potential duration in purified LQTS 3-specific cardiomyocytes.
To prove the concept that these cells could be used for drug screenings, we performed automatic planar patch clamp analysis (Nanion Technology) with purified wild-type and LQTS 3-specific cardiomyocytes. Voltage ramps

showed the typical inward and outward currents of iPS-derived cardiomyocytes. Action potential were measured automatically at different pacing frequencies and LQTS-specific cardiomyocytes showed the characteristic prolongation at low rates.
Hence, LQTS 3-specific cardiomyocytes can be purified form disease-specific iPS with a lentiviral strategy, maintain the specific hallmarks of the disease and are suitable for automated drug screening by planar patch clamp analysis.

ISOLATION OF HUMAN C-KIT+ CARDIAC PROGENITOR CELLS TO IMPROVE OUR UNDERSTANDING OF CARDIAC TRANSCRIPTIONAL REGULATION

Claire N. Medine, Judy Fletcher, Franziska Sendfeld, Nicholas L. Mills, Ian Wilmut
MRC Centre for Regenerative Medicine, The University of Edinburgh, Edinburgh, United Kingdom

It was previously believed that the heart was a terminally differentiated organ, with limited or no regenerative capacity. However, over the last decade compelling evidence suggests that the heart does undergo regeneration with a limited population of resident progenitor cells able to replenish cardiomyocytes lost due to injury throughout adult life. The therapeutic manipulation of resident cardiac progenitor cells could transform outcomes in patients with heart failure if these cells can be harnessed for myocardial regeneration. In recent years, the search for cardiac progenitor candidates has gathered momentum, and several populations of resident cardiac progenitor cells have now been isolated in rat, mouse, dog, porcine and human hearts using a variety of stem cell markers. With a variety of cardiac progenitor populations now described it is important that we fully understand the properties and differentiation potential of these progenitor populations. We describe the isolation of c-kit+ potential cardiac progenitor cells from atrial appendages of patients undergoing coronary artery bypass or valve replacement surgery (n=6) and from human fetal hearts (n=6). C-kit+ magnetic activated cell sorting (MACS) was used to isolate c-kit+ cells that were expanded in culture. These populations were CD45-, CD34-, but positive for CD146, CD105, KDR and the early cardiac transcription factors Mef2c, GATA4, Nkx2.5 and Isl1. The c-kit+ populations were able to differentiate in vitro to cardiomyocytes and endothelial cells. To improve our understanding of the dynamic networks of transcriptional regulation in cardiac progenitor cells both fetal and adult c-kit+ cardiac progenitors were used as a tool for gene profiling to identify key genetic differences between the populations. Single-cell gene expression techniques also allowed us to detect variations among cells in seemingly homogenous populations. This allowed us to detect overlapping and non-overlapping expression patterns and thus provide novel insights into the complex networks of transcriptional regulation in cardiac progenitor cells. Understanding the transcriptional regulation of cardiac progenitor cells will identify novel approaches for cellular reprogramming and permit us to develop robust methods for isolating and expanding these cells for clinical application in the treatment of patients with heart failure.

Gene Signatures of Heart Chamber Myocytes Identify Chamber-Specific Cardiac Progenitors

Peter Andersen[1], Laviel Fernandez[2], Hideki Uosaki[2], Chulan Kwon[2]
[1]Johns Hopkins Univ, Baltimore, MD, [2]Johns Hopkins Univ, Baltimore, MD, United States

Pluripotent stem cell (PSC)-derived cardiomyocytes have emerged as a promising cell source to repair damaged myocardium. However, due to the lack of molecular and functional information of early cardiomyocytes, it remains unclear which types of myocytes are generated from PSCs. Here, we isolated atrial, right ventricular, and left ventricular myocytes from embryonic hearts and examined their properties by microarray and patch-clamp analyses. We found that a large number of genes are differentially regulated in each of the chamber myocytes, including genes encoding transcription factors, surface receptors and channel proteins. Moreover, they exhibited distinct electrophysiological properties. PSC-derived myocytes were composed of cells with properties of the embryonic atrial, right ventricular, and left ventricular myocytes, indicating myocardial heterogeneity at molecular and functional levels. Strikingly, some of their gene signatures remained in early cardiac progenitors and this allowed us to purify cardiac progenitors giving rise to each chamber cells. This study provides defined parameters to distinguish

cardiomyocytes of different chambers and to isolate chamber-specific cardiac progenitors from PSC systems, which will be instrumental for cell transplantation therapy and for diagnosis and drug screening of heart diseases.

TREATMENT WITH THE HISTONE METHYLTRANSFERASE INHIBITOR BIX01294 ENHANCES THE CARDIOPOTENCY OF BONE MARROW STEM CELLS

Jinpu Yang[1], Carol A. Eisenberg[2], Leonard M. Eisenberg[2]
[1]New York Medical College, valhalla, NY, United States, [B]Physiology, [1]New York Medical College, valhalla, NY, United States

Heart disease is the leading cause of death in the US. Since the optimal treatment for the damaged or diseased heart is to replace dysfunctional myocytes, great effort has been made to develop stem cell therapies for regenerating cardiomyocytes. Bone marrow (BM) has long been considered a potential stem cell source for cardiac repair due to its abundance and accessibility; however, the capacity of this tissue to generate cardiomyocytes has been low. To improve the cardiac competency of BM cells, we screened various pharmacological reagents and molecules that were previously shown to assist the acquisition and/or maintenance of stem cell pluripotency, for their effect in broadening the differential potential of BM cells. Among the pharmacological reagents we screened, only BIX01294, a selective inhibitor of G9a histone methyltransferase (HMTase), was able to reprogram BM cells to a cardiopotent phenotype. This finding was indicated by upregulation of genes identified with precardiac progenitors (Brachyury, Mesp-1 and Isl-1). Targeting G9a HMTase by shRNA knockdown provided supporting evidence that the expression of these cardiac progenitor markers resulted from the inhibition of this enzyme. Time course studies established that 48 hr treatment with 8μM BIX01294 was optimal, and that the subsequent removal of the drug allowed cells to differentiate in response to the cardiogenic inducing factor Wnt11. When pretreated with BIX01294, BM cells exhibited a more profound response to Wnt11, as shown by the high level expression of myocardial genes and proteins, including Nkx2.5, Gata4, Hand1, Hand2, Tbx5, myocardin, β-MHC, α-actinin, and titin. In addition, we found that Trichostatin A (TSA), a broad inhibitor for histone deacetylases (HDACs), and the DNA demethylating agent 5-azacytidine were able to synergize with BIX01294 in promoting cardiac gene expression by BM cells. In summary, we report that inhibition of histone methyltransferase using BIX01294 reprograms BM cells and broadens their cardiac potential. These data indicate that treatments with pharmacological inhibitors that promote specific epigenetic modifications may have utility for developing stem cell sources for cardiac repair and regeneration.

THE COMBINED TRANSPLANTATION OF TWO DIFFERENTLY-PROCESSED HUMAN SECONDARY CARDIOSPHERES IS THE OPTIMAL STRATEGY FOR CARDIOVASCULAR REGENERATION AND INFARCT REPAIR.

Hyun-Jai Cho, Ho-Jae Lee, Ju-Young Kim, Jooeun Lee, Sahmin Lee, Han-Mo Yang, Yoo-Wook Kwon, Hyo-Soo Kim, Young-Bae Park
Seoul National Univ, Seoul, Korea, Republic of

Background: Adult heart possesses resident cardiac stem or progenitor cells. Of them, *ex vivo*-expanded cardiosphere-derived cell (CDC) is one of promising candidates to repair damaged hearts. We previously reported that the generation of murine and human secondary cardiospheres from CDCs is the effective cell processing strategy to improve the therapeutic efficacy. Compared with monolayer-cultured CDCs, both Oct-4, (a cellular potency marker) and VEGF (a paracrine marker) was markedly up-regulated during secondary CS formation. However, enhancing the cardiopoietic regenerative potential of cultured cells would be irreconcilable with promoting the secretory activity of cells for paracrine humoral effects.
Objectives: We aimed to optimize cell processing strategy to escalate regenerative

potentials as well as to enhance paracrine effects. We hypothesized that the combined approach using two different processing and mixed transplantation thereafter would be desirable to maximize therapeutic benefits.
Methods and Results: During secondary CS formation, we found that ERK pathway played a directional role toward cellular potency or paracrine capacity. Therefore, we generated secondary CSs using two different methods; ERK activation and inhibition. When we stimulated the ERK pathway during secondary CS generation by adding EGF, TGFβ and bFGF in medium, VEGF expression was upregulated. Conversely, when we blocked the ERK pathway by adding receptor tyrosine kinase-1 (RTK-1) and TGFβ blockers and withdrawing EGF in culture medium, Oct-4 expression was increased up to 20-folds.
Next, to trace cells *in vivo*,
we tagged two differently-processed secondary CSs by green and red nanoparticles, respectively, and transplanted 3 x 10^5 cells (1.5 x 10^5,
each) into the infarcted heart of athymic nude mice. Three days after myocardial infarction and cell injection, we confirmed human VEGF secretion in the tissue using human specific VEGF antibody. VEGF was mainly secreted from the secondary CS processed under ERK stimulating condition. Interestingly, we observed secondary CS-derived cardiomyocyte-like cells in the peri-infarct zone at day 14. Cardiomyocyte-like cells were mainly developed from the secondary CS processed under ERK inhibition condition.
Compared with the injection of PBS, CDCs and secondary CSs generated by previous single culture condition, the combined transplantation of two differently-processed secondary CSs markedly increased capillary density at day 14. Furthermore, echocardiography showed that LV dimensions at both systole and diastole were significantly smaller while LV systolic function was greater in the combined transplantation group. In accordance with the physiologic data, Masson's trichrome staining revealed LV thickness and dimension were preserved and fibrotic scar area was reduced in the combined transplantation group.
Conclusions: We demonstrate that ERK pathway plays a directional role in the cell processing *in vitro* and the combined transplantation
of two differently-processed human secondary CSs is a promising strategy to maximize therapeutic benefits through enhancing cardiopoietic regenerative potentials and promoting paracrine humoral effects.

LINEAGE-SPECIFIC MOSAICISM IDENTIFIES RENEWING CARDIAC PROGENITOR CELLS.

Lincoln T. Shenje, Peter Andersen, Hideki Uosaki, Laviel Fernandez, Peter Rainer, Dong Lee, David Kass, Chulan Kwon
Medicine, Johns Hopkins School of Medicine, Baltimore, MD, United States

Cardiac progenitor cells (CPCs) must make the proper decisions to control their number to sustain the rapid heart growth. However, it is unknown if stem cell-like CPCs are available for the process. Here, we demonstrate the presence of a small number of renewing CPCs (rCPCs) and their niche, where CPCs remain proliferative and change fates as they exit the niche. Genetic ablation of the cell-fate regulator Numb and its homologue Numblike depleted CPCs in this niche, leading to an atrophic heart and embryonic lethality. We rescued the lethality by lineage-specific mosaicism and traced CPCs lacking Numb and Numblike. Mutant CPCs normally differentiated into cardiovascular cells, but failed to become rCPCs. The phenotype was recapitulated by deleting β1-integrin, a conserved stem cell regulator that is associated with Numb. Our study indicates that rCPCs serve as a renewable source of CPCs and may provide a stem cell-niche paradigm for heart biology.

A METHOD FOR THE ISOLATION OF PHENOTYPICALLY STABLE SELF-RENEWING CARDIAC STEM CELL LINES

Georg Weitzer
Max F. Perutz Laboratories, Medical University of Vienna, Vienna, Austria

Preparative FACS has generated numerous cell populations from heart tissues which have been characterized as somatic stem cells. However, none of these cell populations characterized and isolated by the presence of markers such as Sca1, c-Kit, Isl1, or CD34 could be subcloned and indefinitely maintained as a phenotypically stable stem cell line so far.
Here we present a method to obtain stable clonally derived stem cell lines from hearts of different age by coculture of triturated heart cells with embryonic stem cells and mitotically inactivated SNL76/7 fibroblasts secreting leukemia inhibitory factor. This mixture of cells creates an environment which mimics a stem cell niche allowing the survival and leukemia inhibitory factor-dependent proliferation of cardiac stem cells. These cardiovascular progenitor cells are enriched by a modified 3T3 protocol and after that embryonic stem cells are removed by either positive or negative selection. 17 cardiovascular progenitor cell lines were independently generated from whole hearts of 2, 22, and 180 day old C57BL/6Jx129Sv and Balb/c mice. The remained diploid over up to 149 passages and exclusively differentiated to cardiomyocytes, smooth muscle cells, and vascular endothelial cells.
While self-renewing they all express the stemness transcription factors Oct4, Sox2, Nanog, and Tert, and at the same time, significant levels of mesodermal and early myocardial transcription factors, Brachyury, Mesp1, Nkx2.5, Isl1, and Mef2C. Neither the presence of activin A nor the presence of low levels of retinoic acid induced differentiation to any endodermal or neuro-ectodermal cell types. Differentiation to atrial, ventricular, and pace-maker cardiomyocytes was enhanced in the presence of Bmp2 and leukemia inhibitory factor attenuated the Bmp2-dependent cardiomyogenesis in a dominant negative manner. Finally removal of SPARC (secreted protein acidic and rich in cysteine), which is secreted by the cardiovascular progenitor cells, significantly, inhibits cardiomyogenesis, and when added induces the temporal upregulation of Brachyury and Nkx2.5 in differentiating cardiovascular progenitor cells.
These results demonstrate the feasibility of the isolation and indefinite maintenance of murine cardiac stem cells, and suggest SPARC as a new player in the regulation of cardiomyogenesis.

ENGINEERED STRATIFIED CELL SHEET BASED ON ENDOGENOUS CARDIAC STEM CELLS AND MYOCARDIUM-LIKE EXTRACELLULAR MATRIX FOR MYOCARDIAL REGENERATION

Heechul Kim[1], Chung Mu Park[2], Jong Tae Kim[1], Hyeong-In Kim[1], Young-Il Yang[2]
[1]Paik Institute for Clinical Research, Inje University, Busan, Korea, Republic of, [2]Inje University School of Medicine, Busan, Korea, Republic of

Endogenous cardiac stem cells (CSCs) provide a promising avenue to regenerate the injured myocardium due to their intrinsic propensity to differentiate into all cardiac cells. However, critical issues including transplantation unit and route should be overcame for translating into clinical application of these cells. Cell sheet engineering using temperature-responsive polymer and cardiomyogenic precursor cells has been approached for myocardial regeneration. This approach appears useful, but cell sheet reveals limitations, such as lack of cell-to-extracellular matrix (ECM) interaction, mechanical fragility, and requiring a complex manipulator to stack single-layered cell sheet into multi-layered cell sheet. To overcome these limitations, we developed a novel one-step method to fabricate a stratified cell sheet based on 3-dimensional (3D) cell culture in the fibrin hydrogel and cell-mediated fibrinolysis and compaction. The fibrin hydrogel provides a temporal matrix for 3D spatial distribution of CSCs. Under stressed culture condition, CSCs begun to rapidly spread, bind to each other and form cellular network throughout the 3D hydrogel. The extracellular space between CSCs and the fibrin revealed the deposition of newly synthesized ECM that composed by collagen type I and IV, laminin, and fibronectin and replaced the preexisting the fibrin hydrogel. Moreover, proangiogenic mRNAs were gradually increased during the culture. Under non-stressed culture condition, the hydrogel was compacted by cell-mediated contraction, released from culture dish, and finally formed a stratified cell sheet. This self-compacted stratified cell sheet was easily manipulable and grafted on the epicardium of acute infarcted heart. CSCs populated in a stratified sheet transepicardially migrated into the injured myocardium and participated the myocardial regeneration. Overall, our unique approach may be broadly applicable to fabricate a stratified CSC sheet for the myocardial regeneration.

CELL-SHEET-BASED BIOENGINEERED HUMAN CARDIAC TISSUE USING PLURIPOTENT STEM CELLS FOR HEART REPAIR AND DISEASE MODELS

Katsuhisa Matsuura[1], Tatsuya Shimizu[1], Yuji Haraguchi[1], Masanori Wada[3], Nobuhisa Hagiwara[2], Teruo Okano[1]
[A]Institute of Advanced Biomedical Engineering and Science, [B]Department of Cardiology, [1]Tokyo Women's Medical University, Tokyo, Japan, [2]I, ABLE CO., Tokyo, Japan

We have developed an original and unique scaffold-free tissue engineering approach, “cell sheet engineering”, using a temperature responsive culture surface, and this technology has been already applied to regenerative medicine of various tissues such as cornea, heart and esophagus in the clinical setting. As the bioengineered three-dimensional cardiac tissue is expected to not only function for repairing the broad injured heart but also to be the practicable heart tissue models for drug screening and the disease models, we have developed the cell sheet-based bioengineered vascularized three-dimensional cardiac tissue. Furthermore the development of human iPS cell technology enables us to create human cardiac tissue. Recently we have developed the novel suspension cultivation system for undifferentiated expansion and the high-efficient cardiac differentiation of human iPS cells. This unique stirring system with the suitable dissolved oxygen concentration was capable of expanding human iPS cells with maintaining the undifferentiated state up to 1×10^8 cells/100 ml in 5 days. Moreover fourteen-day culture with the serial treatments of suitable growth factors and a small compound produced robust embryoid bodies that showed the spontaneous beating and the cell number was increased to around 8×10^7 cells/100 ml vessel. Flow cytometric analysis revealed that about 80% and 5% of cells were cardiac troponin T positive cardiomyocytes and CD31 positive endothelial cells, respectively. When cells after cardiac differentiation and the enzymatic dissociation were cultured on temperature-responsive culture dishes, the spontaneous and synchronous beating was observed accompanied with the intracellular calcium influx all over the area even after cell sheets were detached from culture dishes by the lowering the culture temperature. High content image analysis revealed that the cardiac cell sheets were mainly composed of cardiomyocytes (80%) and partially mural cells (20%). Consistent with the results that the mRNA expression of pluripotency genes such as Oct3/4 and Nanog were further diminished after the process of fabricating cardiac ell sheets, undifferentiated cells such as Oct3/4 expressing cells were not observed. Furthermore, extracellular action potential propagation was observed between cell sheets when two cardiac cell sheets were partially overlaid, and this propagation was inhibited by the treatment with some anti-arrhythmic drugs. When the triple layered cardiac tissue was transplanted onto the subcutaneous tissue of nude rat, the spon-

taneous pulsation was observed at 2 weeks and engrafted cardiomyocytes were vascularized with the host tissue-derived endothelial cells. These findings suggest that cardiac cell sheets formed by hiPSC-derived cardiomyocytes might have sufficient properties for the creation of thickened cardiac tissue. Now we are developing the vascularized thickened human cardiac tissue by the repeated layering of cardiac cell sheets on the artificial vascular bed in vitro. In this session, I am going to show our recent progress of cell-sheet-based cardiac tissue engineering for heart tissue repair and as possible applications for human heart disease models.

CARDIOMYOCYTE DIFFERENTIATION FROM HUMAN PLURIPOTENT STEM CELLS IN CHEMICALLY DEFINED E8 MEDIA

Yongshun Lin, Kaari Linask, Wen Xie, Yanjun Qin, Jeanette Beers, Guokai Chen
National Heart, Lung, and Blood Institute, Bethesda, MD, United States

Because of their unique capacity to generate any cell type of the human body, human pluripotent stem cells (hPSCs), including embryonic stem cells (ESCs) and induced pluripotent stem cells (iPSCs), hold great promise for drug discovery and cell therapy. To provide an effective tool to facilitate research use and satisfy the clinical demands of hPSCs, we previously developed a simplified chemically defined media (E8) for hPSCs derivation and culture, which is completely free of human and animal products including serum and albumin. In this study we developed a protocol for the differentiation of clinical-grade cardiomyocytes from hPSCs on the defined E8 medium platform. By modulation of exogenous and endogenous recombinant cytokines and hormones, such as Wnt, BMP, and Activin, as well as the components (TGFb, FGF2, and insulin) of E8, we demonstrate that beating cardiomyocytes can be efficiently induced from hPSCs (ESCs and iPSCs) using E8 based medium. E8 can be successfully applied in both 2D monolayer and 3D embryoid bod (EB) culture. Since the whole procedure is under fully defined conditions, our approach provides a promising and powerful tool for generating desired cardiac lineages that could be utilized in basic research and clinical transition study.

Improving cardiomyogenic differentiation of human pluripotent stem cells (hPSCs) in defined conditions by the application of small molecules

Kepf Henning, Ruth Olmer, Gerald Dräger, Ulrich Martin, **Robert Zweigerdt**
REBIRTH - Center for Regenerative Medicine, Hannover, Germany

Improving cardiomyogenic differentiation of human pluripotent stem cells (hPSCs) in defined conditions by the application of small molecules
Estimations suggest that more than one billion cardiomyocytes per patient will be required for cardiac replacement therapies after myocardial infarction. Human pluripotent stem cells (hPSC) present an attractive cell source to generate these large amounts, not only for the envisioned cell therapies, but also for drug screening and cardiotoxicity tests.
For these purposes an efficient hPSC differentiation process is highly demanded, preferentially in defined and scalable conditions. To this end we and others have successfully developed scalable expansion culture of hPSCs in suspension culture.
However, efficient cardiomyogenic differentiation strategies for these cultures were not described yet. Towards this end we have tested chemical compounds including p38 MAPK- and Wnt- pathway modulators alone and in combination in multi well assays and monitored cardiac differentiation by an Nkx2.5-eGFP reporter line, KDR/PDGFR-α FACS, and cardiac Troponin T-specific immunoflourescence staining. Promising candidate combinations were subjected to hPSC mass suspension cultures. In this context we tested a) different culture platforms particularly focusing of chemically defined culture media and b) tested several hPS cell lines to show general applicability and robustness of our novel conditions.

We have achieved an efficient hPSC differentiation process i.e. observed a level of >60% CMs induction based on small molecules enabling the derivation of large amounts of functional cardiomyocytes in chemically defined conditions.

TRIIODOTHYRONINE TREATMENT PROMOTES THE MATURATION OF HUMAN PLURIPOTENT STEM CELL-DERIVED CARDIOMYOCYTES

Xiulan Yang, Veronica Muskheli, Mark Saiget, Lil Pabon, Hans Reinecke, Charles E. Murry
University of Washington, Seattle, WA, United States

Human pluripotent stem cell-derived cardiomyocytes (hPSC-CMs) hold great promise for regeneration of diseased hearts. There is, however, a risk of arrhythmias following hPSC-CMs transplantation into injured hearts. Enhancing their maturation may reduce the chance of arrhythmia after transplantation. Tri-iodo-L-thyronine (T3) is reported to be a prime driver of sheep cardiomyocyte maturation. In this study, we tested the hypothesis that T3 treatment of hPSC-CMs would result in the maturation of their structural and contractile properties to a more adult-like phenotype. Compared to control cells, T3-treated cells showed significant differences in morphology, including increased cell size and anisotrophy, increase in the percentage of cardiomyocytes with multinucleation, as well as an increase in sarcomere length. We measured the contractile performance of these cells and noted a significant increase of departing velocity. Q-PCR showed that the T3-treated cells have a higher alpha-myosin heavy chain, sarcoplasmic reticulum Ca2+ ATPase, and a lower level of beta-myosin heavy chain and Connexin 40. Altogether, these findings indicate that T3 enhances the maturation of human pluripotent stem cell derived cardiomyocytes.

MODELING HYPERTROPHIC CARDIOMYOPATHY USING HUMAN IPS CELL DERIVED CARDIOMYOCYTES

MOHAMMAD A. MANDEGAR, JENNIE YOO, LUKE M. JUDGE, TRIEU NGUYEN, JUAN A. PEREZ-BERMEJO, YUICHIRO MIYAOKA, PAWEENA P. LIZARRAGA, AMANDA CHAN, NATHANIEL HUEBSCH, MATTHEW J. SPINDLER, IAN SPENCER, PO-LIN SO, BRUCE R. CONKLIN
Cardiovascular Disease, Gladstone Institutes, San Francisco, CA, United States

Hypertrophic cardiomyopathy (HCM) is the most common inherited form of cardiovascular disease. It is the leading cause of sudden cardiac death in young athletes, and its prevalence has been estimated to be as high as 1 in 500 within the general population. The majority of HCM-associated mutations have been identified in sarcomeric proteins, in particular the cardiac isoform of Myosin Binding Protein C (*MYBPC3*). Our research is focused on elucidating the molecular basis for how a common 25bp deletion in intron 32 of *MYBPC3* (*MYBPC3*$^{\Delta 25}$) might lead to the development of HCM. Despite the high prevalence of this mutation - with an estimated 50 million carriers worldwide - remarkably little is known about the molecular mechanisms that may lead to the development of HCM. The current hypothesis posits that this mutation causes significant structural modifications at the MYBPC3 C-terminus that alters its binding affinity for sarcomeric proteins involved in regulating actomyosin sliding filament motion (e.g., Titin and LMM-Myosin), and these changes ultimately lead to the development of HCM phenotypes. However, investigating the relationship between *MYBPC3*$^{\Delta 25}$ deletion and the HCM phenotype has been hampered by the lack of adequate cellular models. Although some in vitro models of HCM have been created with human induced pluripotent stem (iPS) cells, none have yet been made for *MYBPC3*.
To overcome these challenges, we are using Transcription Activator-Like Effector Nuclease (TALEN)-directed homologous recombination to genetically engineer homozygous and heterozygous knockouts (KO) of *MYBPC3* and the *MYBPC3*$^{\Delta 25/\Delta 25}$ variant into isogenic iPS cell lines. We have genetically engineered both heterozygous and homozygous *MYBPC3* KO iPS cell lines by inserting an artificial early stop codon into exon 1 of *MYBPC3*. Preliminary results suggest a differential beat rate phenotype in the heterozygous KO iPS-CM compared to WT control iPS-CM, and delayed cardiomyocyte maturation in homozygous KO iPS-CM compared to WT control and heterozygous KO lines. We are currently in the process of determining robust cellular phenotypes using electrophysiology and cellu-

lar morphometric assays. In addition, we are engineering a FLAG epitope tag to reveal key binding partners of the 'wild type' and mutant forms of MYBPC3 via immunoprecipitation from iPS-derived cardiac myocytes. These lines will be used in comparative phenotypic and proteomic analyses to yield critical insight into the molecular mechanisms of this disease. We expect these studies will improve our understanding of the pathological mechanisms underlying HCM and could lead to the identification of drug targets and enhanced treatment options for HCM patients.

DRIVING IN VIVO HEART PROGENITOR CELL FATE AND VASCULOGENESIS VIA CHEMICALLY MODIFIED MRNA

Lior Zangi[1], Kathy Lui[3], Alexander von Gise[1], Derrick Rossi[2], William Pu[1], Kenneth Chien[4]
[A]Cardiology, [B]Cellular and Molecular Medicine, [1]Boston Children's hospital, Harvard medical school., Boston, MA, United States, [2]Department of Stem Cell and Regenerative Biology, Harvard University, Boston, MA, United States, [3]Department of Cell and Molecular Biology and Medicine, Karolinska Institutet, Boston, Sweden

Translation of our growing knowledge of molecular pathogenesis into effective therapy has been hampered by limitations of available gene transfer platforms. RNAs containing chemically modified nucleotides ("modRNAs") have been shown to be non-toxic, non-immunogenic, and efficiently translated into functional proteins. Here, we show that modRNAs are a novel and efficient gene transfer platform for heart and skeletal muscle. We reasoned that the "pulse-like" expression kinetics of modRNAs might be used to express paracrine factors as cell fate switches to redirect progenitor cell fate and thereby enhance long term organ repair. As proof of concept, we used modRNA to drive high level expression of human vascular endothelial growth factor-A (VEGF-A) in the heart. Administered in the setting of myocardial infarction (MI), VEGF-A modRNA markedly improved heart function and enhanced long-term survival of recipients. This improvement was largely due to reduced infarct size and increased capillary density in the peri-infarct myocardium. Enhanced myocardial vascularization was in part due to a novel activity of VEGF-A on Wilm's tumor 1 (Wt1)-expressing epicardial heart progenitors: VEGF-A mobilized and augmented this heart progenitor pool, and redirected their differentiation towards vascular cells. Our results establish a novel therapeutic paradigm in which transient application of paracrine factors alters progenitor cell behavior and fate to achieve sustained improvement of therapeutic endpoints. modRNA represents a new, highly translatable, cell-free approach to implement this therapeutic paradigm and enhance repair of the heart, vasculature and potentially other solid organs.

ISOLATION OF CARDIAC PROGENITORS FROM MURINE AND SIMIAN POST MORTEM CARDIAC TISSUE

Daisuke Kami, Midori Nakata, Tomoya Kitani, Satoshi Gojo
Kyoto Prefectural University of Medicine, Kyoto, Japan

Background
Cell-based regeneration therapies hold great promise and potential for new area in clinical medicine, although some obstacles still remain to be overcome for a wide range of clinical applications. Currently, the cells for transplantation were derived from either autologous or allogeneic tissue. The former has a drawback that the quality of donor cells could depend on the patient's condition, and the quantity could also be limited. A phase I clinical trial

named ALCADIA (ClinicalTrials.gov Identifier: NCT00981006), which stand for AutoLogous human CArdiac-Derived stem cell to treat Ischemic cArdiomyopathy, has been completed. Hereof, it has taken several weeks to grow cardiac progenitors up to acquire the cell number to be needed for the treatment. To solve these problems, we are investigating the potential of allogeneic cardiac progenitors transplantation derived from post mortem human heart.
Objective
To examine whether cardiac progenitors could be isolated from murine and simian post mortem cardiac tissue.
Methods
Cardiac progenitors were isolated from the right and left atrial appendage and free wall of bilateral ventricles of mice (10-18 weeks old, C57BL/6), and cynomologus monkey (5 to 9 years old, Macaca fascicularis). Cardiac tissue was harvested either at just sacrifice or 24 hours post mortem. The isolation of cardiac progenitors was carried out according to the current protocol for ALCADIA. The cardiac progenitors were cultured in a DMEM/F12 supplemented with 10% FBS and 40 ng/ml of basic FGF onto 60-mm Collagen I coated culture dish. At two to three passages of cardiac progenitors, we performed the cellular characteristics analysis, which included growth rate, RT-PCR, FACS, and microarray analysis.
Results
Cardiac progenitors could be isolated from both murine and simian heart 24 hours post mortem. Compared with cardiac progenitors from the heart to be harvested just after sacrifice, post mortem cardiac progenitors had longer lag phase after seeding, and they demonstrated the similar characters in respect of the surface antigens and transcriptional gene expression. FACS analysis showed cardiac progenitors expressed CD29, CD90, and CD105, and were negative for CD31, CD45, and CD117. RT-PCR demonstrated that cardiac progenitors were positive for Gata4, Tbx5, and Nkx2.5 as markers of early cardiac development, and Klf4 and cMyc as markers of pluripotency. Otherwise, Oct4, Sox2, and Nanog as markers of pluripotency, and Brachyury, and Mesp1 as markers of mesodermal stem cells, and c-kit as a marker of somatic stem cells were negative in both fresh and post mortem population.
Imprications
These results indicate allogeneic cardiac progenitor cell transplantation using post mortem heart feasible. This strategy could easily transfer to off-the-shelf product model in pharmaceutical company.

W-3153

INCREASE OF CAPILLARY DENSITY DURING PREGNANCY IN MOUSE IS CAUSED BY HORMONES

Daniel Korzus[1], Kristina Thaben[1], Stuart Walsh[2], Stefan Jovinge[3], Bernd Kurt Fleischmann[1], Michael Hesse[1]
[1]Institute of Physiology I, University of Bonn, Bonn, Germany, [2]Department of Cardiology, Children's Hospital Boston, Boston, MA, United States, [3]Lund Strategic Research Center for Stem Cell Biology and Cell Therapy, Lund University, Lund, Sweden

During pregnancy the organism undergoes a variety of adaptive physiological changes. The cardiovascular system is strongly affected and its response characterized by the hypertrophy of the heart. The molecular mechanisms underlying these adaptations are poorly understood. Because of the recently developed concept of resident organotypic stem cells in the cardiovascular system, our aim is to explore the potential involvement of these cells and the related signaling cascades in this adaptation process in the heart.
We have analyzed cell proliferation using immunostainings against pHH3/Ki67 in mouse hearts at different stages during pregnancy. The average percentage of Ki67+ nuclei per total nuclei in cardiac sections increased from virgin controls to gestational day 3 (GD3) and peaked at GD14. Enhanced proliferation immediately stopped after delivery. Co-staining revealed that approximately 2/3 of the proliferating cells were fibroblasts and 1/3 endothelial cells (ECs). The lack of cardiomyocyte (CM) proliferation was corroborated using BrdU pulse chase experiments examined by Langendorff perfusion. The results were confirmed by flow cytometric analysis. The proliferation of fibroblasts and ECs reflects angiogenesis, as could be measured by an increase of capillary density, and extracellular matrix remodeling known to occur during pregnancy induced hypertrophy. To analyze the role of hormones in these physiological adaptive processes, plasma levels of progesterone, prolactin and estrogen were quantified. Progesterone- and prolactin- levels showed their maximal blood concentrations at GD14 and declined at the day of

delivery coinciding with the course of proliferation, whereas estrogen showed two distinct peaks at GD3 and GD18. To mimic the action of pregnancy hormones we implanted hormone-pellets with consistent release for 21 days in ovariectomized mice subcutaneously. Capillary density was significantly increased in mice receiving progesterone-pellets alone or in combination with estrogen-pellets without induction of hypertrophy. Thus, increase of capillary density is directly caused by pregnancy hormones.
We are currently investigating the mechanisms underlying pregnancy hormones induced proliferation in cardiac ECs and fibroblasts.

BIOLOGICAL PACEMAKER DERIVED FROM PLURIPOTENT STEM CELLS FOR TREATMENT OF BRADYCARDIA

Kumi Morikawa[1], Yoshinori Yoshida[2], Yasuaki Shirayoshi[1], Ichiro Hisatome[1]
[1]Department of Regenerative Medicine and Therapeutics, Graduate School of Medical Science, Tottori University, Yonago, Japan, [2]Department of Reprogramming Science, Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan

An inward current (designated I_f) activates the membrane hyperpolarization in cardiac pacemaker cells at sinoatrial node (SAN), and is responsible for spontaneous pacemaker activity and rate control. Of the four hyperpolarization-activated cyclic nucleotide-gated (HCN) ion-channel family genes, which contribute to native I_f current, HCN4 is the dominant isoform in cardiac pacemaker cells. Although the progress of biological pacemakers has been made with viral vectors, human embryonic stem cells, and adult human mesenchymal stem cells as delivery systems, no approach to biological pacemaking has been to utilize the HCN4 gene or HCN4 positive cardiac pacemaker cells. Cardiac pacemaker cells can be extracted from the differentiating mouse embryonic stem (mES) cells on the basis of their specific expression of ion-channel HCN4 at SAN. We have established the green fluorescent protein (GFP) knock-in mESCs at HCN4 locus (H7 clone) and characterized pace-making cells derived from H7 ES cells by isolation of GFP-positive cells using embryoid body (EB) differentiating system.
The expression of GFP was specifically restricted at their contracting region in differentiating H7 EBs. Cell sorting revealed that a few cells (0.1~0.5%) of contracting H7 EBs were GFP positive. Approximately 80% of GFP+ cells showed the spontaneous beating activity, which was based on cesium sensitive action potentials. Sorted GFP+ cells expressed endogenous HCN4 (HCN4+) and had essentially the same properties as the cardiac pacemaker cells at SAN. At first, GFP+ cells had the common gene and protein expression profiles with cardiac pacemaker cells, for examples, pacemaker specific makers such as HCN4, Cav3.1 and Connexin43 as well as cardiomyocyte specific maker, Tropomyosin C. Second, I_f currents were confirmed by patch-clump analysis. Finally, GFP+ cells were capable of actively responding to adrenergic stimulation and cholinergic repression.
We further investigated whether mESC-derived HCN4+ cells can restore myocardial electromechanical properties. Using imaging techniques, we demonstrated that HCN4+ cells established electrical coupling with HL-1 cells, a cardiac muscle cell line derived from the mouse atrial cardiomyocytes tumor, to induce rhythmic electrical and contractile activities *in vitro*. Similarly, the transplanted HCN4+ cells paced the hearts of rat with complete atrioventricular block, indicated that HCN4+ cells could substitute for pacemaker cells and elicit an ectopic rhythm *in vivo*.
These results demonstrated the potential of mESC-derived HCN4+ pace-making cells to act as a rate-responsive biological pacemaker and for future myocardial regenerative medicine to bradycardia.

ALLOGENICITY OF HUMAN CARDIAC STEM/PROGENITOR CELLS

Laura Lauden, Wahid Boukouaci, Noemie Dam, Ryad Tamouza, Dominique Charron, **Reem Al-Daccak**
UMRS940, INSERM, Paris, France

Rationale: Transplantation of allogeneic cardiac stem/progenitor cells (CPC) in experimental myocardial infarction promoted cardiac regeneration and improved heart function. While this has enhanced prospects of using allogeneic CPC for cardiac repair, the mechanisms regulating the behavior of these allogeneic cells, which are central to clinical applications, remain poorly understood.
Objective: T cells orchestrate the allogeneic adaptive immune response whereas natural killer (NK) cells are major players of innate immune response. Therefore, to provide insight into the mechanisms regulating the immunologic behavior of human CPC (hCPC), we investigated the T and NK cells response to allogeneic hCPC.
Results: We demonstrate that, whether under inflammatory conditions or not, hCPC do not trigger conventional allogeneic Th1 or Th2 type responses but instead promote a regulatory response and an allogeneic-driven immunomodulation, both dependent on B7 family member programmed death-ligand 1 (PD-L1). Activated NK cells were able to lyse allogeneic hCPC, but under inflammatory conditions a drastic decrease in this killing was observed. hCPC were also able to modulate the NK cytolytic activity towards target cells and this was accompanied by a decrease in the expression of NK activating receptors. Although, the mechanisms underlying the behavior of NK cells against allogeneic hCPC are still under investigation, our data indicate that hCPC are probably protected against NK cell lysis upon their application in an inflammatory context as after myocardial infarction.
Conclusions: Collectively our data reveal that hCPC in allogeneic settings have a “tolerogenic” immune behavior. Our study attributes an important role for PD-L1 and raises the possibility of using PD-L1 expression as a marker to identify and select low-risk high-benefit allogeneic cardiac repair cells.

SILENCED ALPHA ADRENERGIC SIGNALLING INHIBITS HYPERTROPHY OF HUMAN PLURIPOTENT STEM CELL-DERIVED CARDIOMYOCYTES

Gabor Foldes[1], Elena Matsa[2], Janos Kriston-Vizi[3], Thomas Leja[1], Stefan Amisten[4], Ljudmila Kolker[1], Maxime Mioulane[1], Karine Vauchez[1], Tamas Aranyi[5], Robin Ketteler[3], Michael Schneider[1], Chris Denning[2], Sian Harding[1]
[1]National Heart and Lung Institute, Imperial College London, London, United Kingdom, [2]University of Nottingham, Nottingham, United Kingdom, [3]University College London, London, United Kingdom, [4]Oxford University, Oxford, United Kingdom, [5]Université d'Evry, Evry, France

The potential of stem cell-based disease modelling is enhanced by the realisation that cardiomyocytes from human embryonic stem cells (hESC-CM) and induced pluripotent stem cells (hiPSC-CM) can be obtained with disease-specificity. Hypertrophy is a high priority target because of its central role in the transition to heart failure. Strikingly, here we found that hiPSC-CM are relatively unresponsive to major hypertrophic signals compared to hESC-CM. We show that the normal alpha-adrenergic receptor 1A subtype (ADRA1A) is not expressed robustly in either cell type. ADRA1A is reversibly silenced during differentiation, accompanied by up-regulation of ADRA1B, resulting in a distinct gene profile from that in adult human cardiomyocytes. Loss of ADRA1A is more pronounced in hiPSC-CM, due to greater epigenetic silencing and more marked up-regulation of HIF-1α, but ultimately both cell types differ from adult in their reliance on active ADRA1B rather than ADRA1A. ADRA1B up-regulation is sufficient in hESC-CM for hypertrophic changes such as cell size, cell volume and ANF. However, in hiPSC-CM, additional decreased G-protein signalling and tonically inhibitory pathway networks suppress the effect of alpha-adrenoceptor stimulation on growth. Superficial similarities between hESC-CM, hiPSC-CM and adult cardiomyocytes may mask complex differences in signalling. These data raise serious questions regarding the hiPSC-CM as a valid model system for certain aspects of cardiac disease.

CELL ASSORTMENT IN ORGAN DEVELOPMENT

Philip Iannaccone[1], Jerry Rhee[1], Steve Iannaccone[1], Talisa Mohammad Nejad[2], Craig Foster[2]

[1]*Pediatrics and Pathology, Northwestern Uninversity, Lurie Children's Research Center, Chicago, IL, United States,* [2]*Dept. of Materials Science and Engineering, University of Illinois in Chicago, Chicago, IL, United States*

Following allocation of stem cells to organ primordia parenchymal cells assort themselves in a robust way allowing further functional organization. The correct placement of cells is more complex than can be managed by direct genetic control. A more likely explanation is self-organizing algorithmic growth. This mechanism has been established as an explanation for the patterns of cell allocation made visible by analysis of mosaic pattern in animals comprising multiple distinguishable lineages, for example in chimeras made by amalgamating embryos of strains differing in RT1 genes or in the expression of reporter genes such as GFP. In the liver, cells are ultimately arrayed without regard to major anatomical features. In the adrenal cortex on the other hand cortical cells form parallel arrays that align with major vessels. Division rule sets that function as cellular automata operating on stem cell pools have been established and are sufficient to explain the dominant patterns observed. In the developing cornea patterns are observed in mouse and rat that like the liver are seemingly unstructured, like islands of one cell lineage in a sea of the other. But within weeks in the mouse and months in the rat the pattern changes to spiral arrays of epithelial cells. The spirals are logarithmic and can be clockwise or counterclockwise with contralateral similarity. Cell division rates, and patterns that double back to create saddle structures belie a simple explanation based on the division of stem cells in the limbal area of the developing cornea. We developed an alternative hypothesis; that shear strain facilitates cell sliding. Shear strain is a result of intraocular pressure, corneal shape and collagen fiber orientation in the stroma. These factors were modeled using sophisticated numerical methods with finite elements analysis. Spiral patterns correlated to directions of maximum shear strain indicating that shear strains on the anterior surface of the stroma may facilitate movement of the epithelial cells into spirals as they slide past each other. The directional stiffness imparted by the collagen fibrils moderately influences the local curvature of the spirals, and hence the local arrangements may be important to the formation of these spiral patterns. While the resulting shear strains from our model do form spirals that are close to logarithmic, the pitch angle is much higher than for observed spirals. Hence shear strain alone is not an adequate explanation for the motion. It could be that that dynamic changes in shear strain coupled with migration and perhaps other phenomena could explain the spiral formation, but further investigation is necessary to fully understand the underlying causes of the spiral generation. Stem cell dynamics and cell assortment are useful probes of processes important in organogenesis.

W-3162

DEVELOPMENT OF AN APPROACH FOR IN VITRO GENERATION OF RETINAL GANGLION-LIKE CELLS BY DIRECT REPROGRAMMING

Valentin Sluch[1], Donald J. Zack[2]
[A]*BCMB,* [B]*Ophthalmology,* [1]*Johns Hopkins University School of Medicine, Baltimore, MD, United States*

The optic nerve is composed of retinal ganglion cell (RGC) axons that relay visual information from the eye to the brain. A number of optic nerve diseases lead to RGC death and vision loss, the most common of which is glaucoma, the second leading cause of blindness in the world. Rodent models have proved useful for the study of optic nerve disease. However, these models represent an approximation of the human condition, and may not replicate all the necessary molecular events involved. Generation of human RGCs in vitro, through either stem cell or direct reprogramming methods, could make possible an approach for medically relevant drug screening that would have advantages over the use of rodent cells. In addition, such cells could provide insights into human RGC development, gene regulation, and general biology.
Unfortunately, stem cell derivation of RGC-like cells is inefficient and time consuming. In an effort to circumvent these challenges, we have been working to develop a direct reprogramming method to convert somatic cells directly into RGCs. Through lentivirus induced overexpression of a set of transcription factors relevant to RGC biology, we were able to transdifferentiate human retinal pigment epithelium cell line cells (ARPE19) to cells with some characteristics of the RGC lineage over a course of three weeks. These induced RGC-like cells (iRGC) exited the cell cycle and exhibited a dendritic arborization pattern reminiscent of RGCs. Immunocytochemistry showed that iRGCs

expressed neuronal markers TUJ1 and MAP2 and expressed the RGC markers CALB2 and BRN3A. qPCR analysis showed upregulation of expression of the following RGC enriched genes - SNCG, THY1, and NHLH2 as compared to negative controls and a transcription factor set for generation of cortical neurons.
In conclusion, we have made progress in generating human RGC-like cells by direct reprogramming of an established retinal pigment epithelium cell line. Using the identified genes necessary for RGC cell fate determination in this system, we hope to develop methodology to convert other cells types such as fibroblasts to RGC-like cells, as well as illuminate important factors for RGC competence. Furthermore, these iRGC cells should provide a valuable resource for drug screening and studying reprogramming mechanisms as well as RGC biology.

MODELING HUMAN CONE PHOTORECEPTORS DEVELOPMENT AND DEGENERATION USING EMBRYONIC STEM CELLS

Gilbert Bernier
Research Center, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada

Inherited juvenile macular degeneration, dry age-related macular degeneration and cone dystrophies represent a major cause of blindness. These pathologies primarily lead to degeneration of cone photoreceptors. Cones are involved in color discrimination and high acuity central vision. However, current source of human cones to model photoreceptor development and disease in vitro does not exist. We report here on the rapid and efficient differentiation of human embryonic stem cells into cone photoreceptors. These cells are amenable to recapitulate the developmental genetics of human photoreceptors and to model cone diseases. We provide one such example by knockdown of the Polycomb group gene BMI1 using shRNA-producing lentivirus, which leads to progressive cone degeneration in vitro.

W-3164

COMBINED CELL AND GENE THERAPY TOWARDS THE TREATMENT OF AGE-RELATED MACULAR DEGENERATION AND DIABETIC RETINOPATHY

Sabiha Hacibekiroglu[1], Iacovos P. Michael[1], Peter Westenskow[2], Brian Ballios[3], Derek van der Kooy[3], Martin Friedlander[2], Andras Nagy[1]
[1]Samuel Lunenfeld Research Institute/Mount Sinai Hospital, Toronto, ON, Canada, [2]The Scripps Research Institute, San Diego, CA, United States, [3]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada

Age-related macular degeneration (AMD) and diabetic retinopathy (DR) are the leading blindness causing eye diseases that affect more than 14 million people worldwide. Both are associated with abnormal and leaky blood vessel growth (neovascularization) caused by an up-regulation of vessel endothelial growth factor (VEGF-A) that leads to vascular leakage, vessel dilatation, tortuosity, haemorrhage and ultimately to cell death and blindness. Current treatments include injection of anti-angiogenics such as anti-VEGF-A antibody (e.g. Ranibizumab). Such treatments improve visual function through regression of abnormal blood vessels. However, patients require monthly injections due to its transient effect, and these treatments cause side effects such as stroke, gastrointestinal perforations and bleeding. We hypothesize that a combination of cell and gene therapy can inhibit abnormal blood vessel growth in eye diseases such as AMD and DR in a controlled and long-term manner, thereby improving vision and diminishing any potential side effects.
The aim of this study is to generate transgenic cells that secrete locally acting anti-VEGF biologics for minimally invasive and controlled long-term administration. We have generated a novel bi-functional VEGF sticky-trap (by modifying the original VEGF trap) that is able to trap VEGF as well as bind (i.e. "stick") to the extracellular matrix (ECM) through binding to heparan-sulphate proteoglycans. This consequently allows inhibition of neovascularization only at the site of expression or administration. We have shown that VEGF sticky-trap, upon intravitreal and subretinal injection, binds to the ECM components of the eye. In contrast to the original VEGF trap, VEGF sticky-trap was un-

detectable in circulation 6 hrs post eye injection. These results indicate that VEGF Sticky-trap remains locally at the site of administration and once it enters the circulation it is degraded within a short amount of time (<8hrs) limiting systemic side effects. Furthermore, we have shown that VEGF sticky-trap is able to inhibit neovascularization in a murine model of DR demonstrating the effectiveness of this biologic in an in vivo model.
Functional retinal pigment epithelium (RPE) cells and mesenchymal stem cells expressing VEGF sticky-traps in a doxycycline-inducible manner have been generated. We have shown that VEGF sticky-trap, expressed by these cells in vitro, is able to bind to cell ECM and trap soluble VEGF only upon doxycycline induction demonstrating a controlled production of VEGF sticky-trap. In addition, we have characterized the ability of the transgenic RPE cells to incorporate into the eye. Currently, we are evaluating the ability of these cells to express VEGF sticky-trap in vivo and to inhibit NV and improve vision in animal models of AMD, such as the RCS rat and the laser-induced chorodial NV mouse.
The injection of these cells into the diseased eye will allow for long-term treatment of AMD and DR by replacing atrophic cells for photoreceptor maintenance, inhibition of neovascularization and regression of abnormal blood vessels controlled at all times by drug (doxycycline, DOX) administration (ON/OFF system). Ultimately, this novel approach may translate into improved treatment options for patients with AMD and DR and contribute to currently on-going clinical trials using RPE cell therapy in patients with AMD.

HUMAN ESC-DERIVED CORNEAL ENDOTHELIAL CELLS FOR THE TREATMENT OF CORNEA DYSFUNCTION.

Soyeon Kwon, Yinyin Chen, Guoping Fan
UCLA, Los Angeles, CA, United States

Cornea endothelial cells (CECs) consist of monolayer cells in hexagonal shape, neighboring each other by tight junction. CEC deficiency due to genetic disorder, trauma, and aging would cause serious corneal edema and blindness in patients. Since adult CECs do not have any capacity to proliferate and self-renew *in vivo,* CEC transplantation is the only treatment. In this study, we attempt to produce CECs from human embryonic stem cells (hESCs). H9 hESCs were first differentiated into neural crest stem cells (NCSCs) by Noggin and SB431542, and NCSCs were affinity-purified via antibody against neural crest marker, HNK-1. The purified NCSCs were cultured with conditioned medium from primary CEC cultures. Approximately 1-2 weeks in culture, we observed a subset of cells exhibiting the polygon morphology of CEC-like cells. We are currently characterizing these CEC-like cells by examining gene expression profiles with a focus on CEC-related markers such as COL8A1, Na^+/K^+-ATPase and Aquaporin1 (AQP-1). We will present our new data on functional characterization of these hESC-derived CECs at the meeting. Our approach may provide a valuable and unlimited source of human CECs for future clinical treatment of CEC deficient disorders.

EFFICIENT DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS INTO RETINAL CELL TYPES

Indumathi Mariappan, Savitri Maddileti, Jamila H. Siamwala
SS Ravi Stem Cell Laboratory, Hyderabad Eye Research Foundation, LV Prasad Eye Institute, Hyderabad, India

Purpose: To establish an efficient protocol to derive retinal cell types from a well characterized Indian human embryonic stem cell line, BJNhem20 (UKSCB accession No. R-08-022).
Methods: The human embryonic stem cell line, BJNhem20 (Inamdar et al., 2009), was cultured and expanded in a feeder-free culture system. Differentiation was initiated by embryoid body (EB) formation in suspension cultures on non-adherent plates with ES medium devoid of bFGF (differentiating medium, DM). After 3 days, the EBs are grown as adherent cultures in neural induction medium (NIM) (DM + 1% N2 supplement) on laminin coated dishes for 3 days. The colonies showing neural rosettes were isolated and further cultured as suspended neurospheres in retinal differentiation medium (RDM) (NIM + 2% B27 supplement) for 3 days. The neurospheres were further plated on laminin coated dishes and maintained as adherent cultures in RDM for about 3 months. The differentiated cells were characterized for retina-specific marker expression by immunofluorescence and RT-PCR analysis.

Results: Using the differentiation protocol described, we could efficiently derive different retinal cell types from the human ES cell line, BJNhem20. Cells expressing retinal progenitor markers (Nestin, Pax6, Chx10, Rx, Otx2, Mitf) and retinal pigmented epithelial (RPE) cells with cobble-stone morphology are observed after 3-4 weeks of differentiation. These early progenitors were amenable for further expansion and enrichment. The mature retinal cells expressed several neural retina-specific markers such as β-III Tubulin, GFAP, MAP2, Rhodopsin, PDE6a, PDE6b and RPE-specific markers such as ZO-1, Tyrosinase, Bestrophin, Mertk, RPE65 and acquired pigmentation in long-term cultures.
Conclusion: The BJNhem20 cells can be efficiently differentiated into neuro-retinal and RPE cells using the differentiation protocol described here.
Key words: Human embryonic stem cells, retinal pigmented epithelial (RPE) cells, retinal dystrophy.

TRANSPLANTATION OF HUMAN RETINAL PROGENITOR CELLS IN RCS RAT MODEL OF RETINAL DEGENERATION: RESCUE OF HOST RETINAL STRUCTURE AND FUNCTION

Jing Luo[1], Peter Shaw[1], Petr Baranov[2], Gary Brooke[3], Caroline Hicks[3], Jessica Lu[1], Hong Ouyang[1], Jiaogang zhao[1], Sara Patel[3], Victoria Reade[3], John Sinden[3], Michael Young[2], Kang Zhang[1]
[1]Department of ophthalmology, Shiely Eye Center, UCSD, San Diego, CA, United States, [2]Schepens Eye Research Institute, Massachusetts Eye and Ear, Boston, MA, United States, [3]Reneuron, Guildford, United Kingdom

PURPOSE: To investigate the therapeutic potential of two human Retinal Progenitor Cells (hRPC) cell lines transplanted into subretinal space of Royal College of Surgeons (RCS) rats to rescue host retinal structure and function.
METHODS: Fetal eye tissue was procured in compliance with IRB and GTP guidelines. 18 week fetal retinal progenitor cells were cultured and expanded to passage 8 and frozen to provide banks of hRPCs. Cells were revived from P8 banks and grown to P9, and transplanted into subretinal space of RCS rats at 2.5x104 cells/µl. RCS rats were injected in the right eye (OD) with A) hRPC line A; B) hRPC line B; C) vehicle only (V, HBSS-NAC); D) untreated controls and compared to baseline control without injection. Group A and B were injected subretinally with 2 µl of cells. Animals were immunosuppressed with oral Cyclosporine A throughout study and IP dexamethasone for 14 days post-transplant. Visual acuity (VA) tests with optokinetic nystagmus (OKN) were conducted at 5 and 12 weeks post-transplant. At 12 week eyes were harvested, and retinal histology assessed.
RESULTS: VA measurement showed that rats treated with hPRC line A (OS vs OD: 0.38 vs 0.46, c/d, $p < 0.05$ or V (OS vs OD: 0.33 vs 0.44, c/d, $p < 0.05$) preserved visual acuity 5 weeks following injection initially. At 12 weeks post-injection the protective activity for VA was not sustained in the V treated animals (OS vs OD: 0.26 vs 0.29, c/d, $p < 0.2$) whereas a sustained protective effect on VA decline was seen in group A (OS vs OD: 0.22 vs 0.47, c/d, $p < 0.01$). VA in hPRC line A treated eyes was better than those treated with V (0.47 vs 0.29, $p<0.05$). There was no difference between treated and untreated eyes in group B and D at both time-points. Statistical analysis of ONL measurement data demonstrated that hRPC line A led to significant preservation of the ONL compared with vehicle ($p<0.05$). Transplant survival was demonstrated in 2/10 Group A eyes. Transplanted cells were distributed throughout the neural retinal layers, including the ONL. Occasional differentiation into rhodopsin and opsin blue positive retinal phenotypes were observed within the surviving graft.
CONCLUSIONS: hRPCs were expanded successfully to P8. hRPC transplantation was well tolerated. No pathologies were noted at 12 weeks after cell treatment. Transplanting hRPCs to the subretinal space of RCS rats can be achieved with immunosuppression without obvious adverse reactions. hRPC line A showed promising results in arresting decline in VA over time in RCS rats , most likely achieved through host photoreceptor rescue rather than by cell replacement.

LITHIUM INCREASES p63 LEVELS IN CULTURED HUMAN LIMBAL EPITHELIAL STEM CELLS.

Agate Noer, Erik O. Johnsen, Aboulghassem Shahdadfar, Charlotte L. Ness, Bjørn Nicolaissen, Morten C. Moe

Ophthalmology, Oslo University Hospital, OSLO, Norway

p63 (isoform ΔNp63α) is a putative stemness marker for limbal epithelial stem cells (LESCs), and is essential for the proliferative potential of stem cells in stratified epithelia. The niche for LESCs is the limbus, located between the clear cornea and bulbar conjunctiva. LESCs are responsible for and able to renew and repair the corneal epithelium throughout life. In a number of disorders and after trauma, limbal stem cell deficiency (LSCD) may occur, and this can be treated by isolation and cultivation of LESCs from a healthy eye followed by transplantation to the affected eye. It is known that the percentage of p63-bright cells affect the success rate of the transplantation. Thus, we wanted to reveal whether lithium, a known Wnt signaling inducing agent, may increase the expression of p63 in human LESC cultures.

Small limbal biopsies (1x1-2mm) were dissected from donor corneas and cultured in a standard medium at $37^{O}C$ and 5% CO_2 under different concentrations of lithium ($LiCl_2$). The cells were cultured for 3-6 weeks and medium was changed every 2-3 days.

The epithelial cells migrated from the limbal biopsy to form an epithelial sheet. Lithium enhanced the expression of p63 compared to controls, and this was confirmed by qRTPCR. Further studies mapping epigenetic alterations of the lithium treatment are currently conducted.Lithium induced upregulation of p63 in LESC could be clinically important by increasing the long term success of limbal stem cell therapy.

DIFFERENTIATION POTENTIAL OF HUMAN LIMBAL FIBROBLASTS AND BONE MARROW MESENCHYMAL STEM CELLS INTO CORNEAL EPITHELIUM

Kishore Reddy Katikireddy, Reza Dana, Ula Jurkunas
Ophthalmology, Schepens Eye Research Institute, Mass. Eye and Ear, Boston, MA, United States

Purpose: Human limbal fibroblasts (LFs) and bone marrow mesenchymal stem cells (BM MSCs) are known for its multipotency. Specifically, a side population of stage-specific embryonic antigen-4 (SSEA4)-positive LFs has been shown to differentiate into a variety of cell types. The present study compared the stem cell characteristics of SSEA4+ and SSEA4- LFs to those of BM MSCs, and determined their potential to differentiate into the corneal epithelial phenotype.

Methods: Human cadaveric limbal tissue (n=6) was treated with dispase to remove the epithelium and endothelium. Single cell suspensions were obtained by digesting the stroma with 0.025% trypsin. Stem cell enrichment was performed by exposure of BM MSCs and LF cells in KnockOut ESC/iPSC medium for 12-15 days. LF and BM MSCs were sorted for SSEA4+ and SSEA4- cells by Magnetic-Activated Cell Sorting. Cell doubling time (CDT), stem cell (SC) marker analysis, and colony forming efficacy (CFE) were performed on sorted LF and BM MSCs. Epithelial phenotype was achieved using induction and differentiation media. Differentiated cells were characterized for corneal cytokeratins (CKs).

Results: After separation, enrichment SSEA4+ LFs 97.4 ± 0.6% and BM MSCs 93.5 ± 0.7% were achieved. The CDT of SSEA4+ LFs was 102 ± 1 hr and SSEA4- LFs was 58.2 ± 1.5 hrs ($p<0.02$). CDT of SSEA4+ BM MSCs was 105 ± 1 hr. and SSEA4- BM MSC was 56.3 ± 2 hrs ($p<0.02$). LF and BM MSC subgroups were negative for pan-cytokeratin. After enrichment, SSEA4+ cells showed the ability to form cell aggregates, while SSEA4- cells were mostly adherent to the culture plates. The transcript levels of SC markers OCT4, SOX2, Nanog and Rexo1 were higher in SSEA4+ than SSEA4- of LF and BM MSCs ($p<0.05$). Upon induction and differentiation, both SSEA4+ LFs and BM MSCs exhibited an epithelial morphology and positivity for CK3, CK12, and CK8, with high CFE ($p<0.001$), whereas the SSEA4- cells exhibited a fibroblast morphology and were negative for corneal epithelial markers.

Conclusion: Although both LFs and BM MSCs express stem cell markers and have some transdifferentiation potential, only SSEA4+ LFs clearly demonstrate the ability to differentiate into corneal epithelial cell phenotype. These findings establish a potential alternative source of corneal epithelial cells that can be harvested for ocular surface reconstruction.

PARTIAL LIMBAL STEM CELL DEFICIENCY (LSCD) - DO WE NEED TO DISTURB THE FELLOW EYE?

Virender S. Sangwan[1], Jayesh A. Vazirani[1], Sayan Basu[1], Indumathi Mariappan[2]

[A]Cornea amd Uveitis Service, [B]Srikant and Sudhakar Stem Cell Laboatory, [1]L V Prasad Eye Institute, Hyderabad, India

Introduction:
Limbal stem cell deficiency(LSCD) clinically manifests with recurrent or persistent epithelial defects, vascularization, pannus formation, conjunctivalization of the corneal surface and loss of normal corneal clarity. Cell based therapy for restoration of the ocular surface in limbal stem cell deficiency has been utilized with good results at various centers across the world.
Purpose:
To report the outcomes of autologous cultivated limbal epithelial transplantation(CLET) utilizing the healthy part of the affected eye or the fellow eye as a source of limbal stem cells in patients with partial LSCD
Methods:
This retrospective study included 70 eyes of 70 patients with unilateral partial LSCD who underwent autologus CLET between 2001 and 2011. The limbal biopsy was taken either from the healthy part of the limbus of the same eye or from the healthy fellow eye. Cells were cultivated using a xeno free explant culture technique. Primary outcome measures were visual acuity and graft survival rate.
Results:
The mean follow up was 17.5 ± 7 months. The mean age of patients was 24 ± 12.5 years. Male:female ratio was 4:1. In 36 eyes the limbal biopsy was taken from the contralateral eye and in the remaining 34 eyes from the ipsilateral eye. The mean pre-operative visual acuity was 1.1 ± 0.6 logMAR, which improved to 0.8 ± 0.6 logMAR(p=0.04). The one year graft survival was 85 ± 7 percent in the contralateral group and 71 ± 8 percent in the ipsilateral group(p=0.74). Failure of limbal transplantation was seen in 9 eyes in the contralateral group and 10 eyes in the ipsilateral group.
Conclusions:
Ocular surface restoration in partial LSCD is possible with cell-based therapy. Outcomes are similar irrespective of whether the limbal biopsy is taken from the healthy part of the ipsilateral eye or the contralateral eye.

REDOX REGULATION OF NEURAL STEM AND PROGENITOR CELLS IN A MOUSE MODEL OF MATERNAL INFLAMMATORY RESPONSE CONTRIBUTES TO MILD BRAIN OVERGROWTH AND AUTISM-RELATED BEHAVIORS.

Janel Le Belle[1], Jantzen Sperry[1], Amy Ngo[1], Harley Kornblum[2]

[A]Psychiatry, [B]Psychiatry and Biobehavioral Sciences, Pharmacology and Pediatrics, [1]UCLA, Los Angeles, CA, United States

Autism Spectrum Disorders (ASD) is a heterogeneous set of developmental disorders characterized by deficits in social interaction and communication. Although ASD is highly heritable, the identification of its causes has been hindered by the heterogeneity of the syndrome. However, one of the more common endophenotypes in autism is brain overgrowth. Although there are known genetic causes of extreme brain overgrowth, a less severe but more pervasive brain overgrowth has been recently identified in retrospective studies using pediatric head circumference and MRI data. No mechanisms for this mild brain overgrowth or the specific behavioral consequences of the overgrowth are currently known. Despite the high heritability of ASD, there are also clear environmental components to autism pathogenesis and one of these known environmental risk factors is maternal inflammation, which may be caused by infection or other factors that induce an immunological response. Our study investigates neuroanatomical, cellular substrates, and the potential signaling mechanisms of brain overgrowth that may be associated with autism using a mouse model of Maternal Inflammatory Response (MIR). It is our hypothesis that mild MIR ex-

posure in early gestation can cause brain overgrowth via mechanisms dependent upon the NADPH oxidase (NOX) enzyme system and activation of the PI3K/AKT signaling pathway. Activation of this pathway is known to enhance neural stem and progenitor cell proliferation and neurogenesis. To test this hypothesis we developed an experimental model of low MIR that results in mild brain overgrowth and increased cortical thickness. We found the MIR-exposed offspring display abnormal autism-like behaviors which correlate with the amount of brain overgrowth. We show that this brain overgrowth is caused at least in part from an increase in stem and progenitor cell proliferation which we observed in the SVZ in vivo and in clonal assays in vitro. Even though our model of mild MIR exposure is based on a single injection of very low dose (8 ug/kg) lipopolysaccharide at an early gestational age (E9), we observe an increase in Iba1+ microglia throughout the brain post-natally. This suggests that there is a sustained immune activation in the brains of MIR-exposed offspring long after the initial exposure to MIR. Finally, we tested the hypothesis that the MIR-induced phenotype is dependent upon the production of reactive oxygen species generated by NOX and the subsequent activation of PI3K signaling by showing that brain overgrowth can be prevented by NOX inhibition.

AUDITORY HAIR CELL FATE DETERMINATION BY COOPERATIVE ACTIVITY OF PAX2 AND SOX2

Judith S. Kempfle[1], Albert SB Edge[2]
[1]Otolaryngology, MEEI Harvard Medical School, Uni Tuebingen, Tuebingen, Boston, Germany, [2]Otolaryngology, MEEI, Harvard Medical School, Boston, MA, United States

The sound-sensing hair cells of the inner ear lack mechanisms for spontaneous regeneration. The cochlea harbors cells with stem cell properties, but even after damage they do not appear to be recruited for hair cell replacement. When cultured in vitro, inner ear stem cells proliferate and differentiate into hair cells, neurons and supporting cells. Two transcription factors, Pax2 and Sox2, play an important role in the differentiation of inner ear stem cells. Our data suggest synergistic effects of Pax2 and Sox2 on expression of transcription factor Atoh1, which is sufficient and essential for the formation of a hair cell from a sensory progenitor cell and is upregulated at the time that hair cells differentiate. Only mouse inner ear stem cells that co-expressed Pax2 and Sox2 in vitro differentiated into hair cells. Overexpression of Sox2 or Pax2 alone increased Atoh1 expression and the number of hair cells in vitro, but co-transfection of both factors led to robust up-regulation of Atoh1 and increased numbers of hair cells from inner ear stem cells. Our biochemical data show that both transcription factors are needed simultaneously in the same cell, where they co-bind to the regulatory region of Atoh1 to activate Atoh1 expression.
We show for the first time that Pax2 and Sox2 act together to activate Atoh1 expression and that both factors have a role in cell fate specification. Our data provide a mechanism that could form the basis for future approaches to regeneration of hair cells.

INNER EAR STEM CELLS FOR TISSUE REGENERATION OF THE AUDITORY ORGAN

Marta Roccio, Stefan Hahnewald, Pascal Senn
Department of Clinical Research, University of Bern, Bern, Switzerland

Hearing impairment is the most frequent human sensory deficit and is mainly caused by the irreversible loss of neurosensory cells in the cochlea.
Previous studies have shown the presence of stem/progenitor cells within the mammalian auditory epithelium, vestibular organs and spiral ganglia, however the regenerative capacity of these organs is extremely poor, in contrast to birds and amphibians.
Stem/progenitor cells can be isolated through a sphere-forming assay in vitro or through prospective isolation using FACS and can give rise in vitro to the differentiated cell types of the tissue of origin. We are currently investigating a number of approaches to efficiently and reliably isolate and expand these cells from rodent as well as human adult and fetal tissues. Besides opening new venues in terms of tissue regeneration and repair, stem cell culture in vitro

provides a useful tool for drug screening to analyze hair cell regeneration and discover novel neurotrophic factors to increase auditory neurons survival.
Even if an exclusive stem-cell based hearing loss therapy may not be feasible in the future, stem cell technology can be used to improve current cochlear implant (CI) technology and therefore translate into a clinical benefit of hearing impaired individuals. We are developing a specifically modified CI electrode array in order to release neurotrophic and chemoattracting factors for induction of neuronal sprouting, guided migration and stable locking of the nerve endings on the electrode surface.
We show here how stem/progenitor cells isolated specifically from the spiral ganglia of early postnatal animals are in vitro expanded and further differentiated into auditory neurons and used for in vitro bioassays. Maturation is tested using marker expression and functionality through electrophysiological measurements on Multi Electrode Arrays (MEAs).
Our approach should lead to a deeper understanding of the regenerative potential within the human inner ear and to novel strategies for optimizing CI prostheses, leading to a gapless interface between the electrode and the neurons.

MOTOR NEURONS GENERATED FROM ALS PATIENT-SPECIFIC IPS CELLS RECAPITULATE KEY ASPECTS OF DISEASE

Evangelos Kiskinis[1], Jackson Sandoe[1], Gabriella Boulting[1], Brian J. Wainger[2], Luis Williams[1], Clifford J. Woolf[2], Kevin Eggan[1]
[1]Stem Cell and Regenerative Biology, Harvard University, Boston, MA, United States, [2]FM Kirby Neurobiology Center, Boston Children's Hospital and Department of Neurobiology, Harvard Medical School, Boston, MA, United States

Amyotrophic Lateral Sclerosis (ALS) is a fatal neurological condition characterized by selective death of motor neurons. Discovery of treatments for ALS and the understanding of mechanisms that cause it have been hampered by an inability to culture motor neurons isolated from patients and by the complex genetic nature of most cases. Patient-specific induced pluripotent stem cells (iPSCs), generated by epigenetic reprogramming of somatic cells, provide an invaluable tool for in vitro disease modeling, and offer a unique opportunity to study how genetic variants that cause neurological diseases modify the human, neural-types sensitive to degeneration. However, the extent to which iPSC-derived neurons are useful for studying adult onset conditions such as ALS, and whether any phenotypes observed in culture are due to disease-causing variants rather than idiosyncratic variation between iPSC-lines, remain significant questions. Here, we show that motor neurons produced from patient-derived iPSCs harboring the ALS-causing SOD1+/A4V mutation exhibited several phenotypes observed in the SOD1 mouse model and ALS patient histology. In particular, ALS-motor neurons decrease in numbers over long-term culture, with the largest motor neurons being selectively lost. Although ALS-derived motor neurons do not form large SOD1 aggregates, a typical pathological phenotype in post mortem patients, they exhibit signs of ER stress and mitochondrial impairment as well as altered electrophysiological properties. Importantly, these findings were absent in other neuronal types and were rescued following correction of the disease-causing genetic variant by homologous recombination, effectively demonstrating that these were direct effects of the ALS-causing mutation. Our results provide an insight to the functional defects that physiological levels of mutant SOD1 lead to, in patient motor neurons and add further credence to the notion that the promotion of protein-refolding is a therapeutic strategy worthy of consideration in SOD1-related ALS. More broadly our study demonstrates that iPSC technology can be used to probe an adult-onset neurological disease such as ALS.

PATIENT-SPECIFIC IPS-DERIVED NEURAL MODEL FOR DD-EDS

Fengming Yue[1], Tomoki Kosho[2], Sakiko Shirasawa[3], Tadayuki Yokoyama[3], Daihachiro Tomotsune[1], Katsunori Sasaki[1]

[A]Dept of Histology and Embryology, [B]Department of Medical Genetics, [1]Medical School of Shinshu University, Matsumoto, Japan, [2]Bourbon Corporation, Kashiwazaki, Japan

Ehlers-Danlos
syndrome (EDS) is a heterogeneous connective tissue disorder involving skin and joint laxity and tissue fragility. Our colleague, Kosho established a new type of EDS, characterized progressive connective tissue fragility (skin hyperextensibility, joint hypermobility, deformity, subcutaneous hematoma), congenital abnormalities (craniofacial feature, delayed motor development, congenital multiple joint contractures), and CHST14 (CSs) mutation, deficiency of D4ST1(DSs), impairment of decorin-mediated assembly of collagen fibrils. It was named D4ST1-deficient EDS (DD-EDS, Kosho type). In this project, we establish patient-specific iPS-derived neural model for DD-EDS to demonstrate pathophysiological features in those mutant neurons. The undifferentiated status and pluripotency of established DD-EDS iPS cells were determined with Oct3/4, Nanog, SSEA-3 and SSEA-4 and teratoma formation. Cellular morphology was found different between DD-EDS-iPS and normal iPS cells, such as small size of cells, obscure cellular boundary, and many vacuoles in cytoplasm. In comparison to normal iPS cells, deficiency for CHST14 resulted in decreased neural progenitor development and diminished mature neurons. CSs and DSs have important roles in neural precursor proliferation, neuronal differentiation, migration and neuroprotection. This is evidenced by decreased DD-EDS iPS-derived neurogenesis, and consistent with clinical symptom, delayed motor development. Patient iPS cell-derived DD-EDS model will be helpful to reveal mechanism of rare heterogeneous disease and discover effective therapeutic drugs.

EVALUATION OF HUMAN EMBRYONIC STEM CELL (HESC)/HUMAN INDUCED PLURIPOTENT STEM CELL (HIPSC)-DERIVED ASTROCYTES AS A MODEL SYSTEM TO STUDY APOLIPOPROTEIN E SECRETION

William L. Blake[1], Lorraine F. Lanyon[1], Claire M. Steppan[1], Sandra J. Engle[1], Kelly Bales[2], Gayathri Ramaswamy[2]
[1]Pfizer/PDM-NCE, Groton, CT, United States, [2]Pfizer/RU-Neuroscience, Cambridge, MA, United States

.
Apolipoprotein E (apoE) is an important lipid transport protein in plasma and brain. In the central nervous system (CNS), apoE is primarily produced by astrocytes and secreted as a high density lipoprotein-like particle. Human apoE has three isoforms: apoE2 (cys112, cys158), apoE3 (cys112, arg158), and apoE4 (arg112, arg158). ApoE is strongly associated with risk for developing Alzheimer's disease (AD) in a genotype dependent manner (apoE4>apoE3>apoE2) . ApoE has been found to play an important role in the removal of β-amyloid $_{1\text{-}42}$ from the brain, a key protein fragment responsible in part for the neuropathology of AD. Increased apoE production in animal models of AD has been associated with a reduction in β-amyloid $_{1\text{-}42}$. Human astrocytoma (CCF-STTG1) cells have been widely used as a model system to study apoE secretion in the CNS. Using the potent LXRα agonist T0901317 as a tool compound, we sought to evaluate the use of hESC and hiPSC derived astrocytes as a model system to study apoE secretion.
We derived astrocytes from both hESCs and hiPSCs, and compared them to primary human astrocytes and the astrocytoma cell line. The hESC/hiPSC-differentiation protocol entailed aggregate formation and subsequent plating of aggregates in the presence of small molecules to establish neural rosettes, treatment of resulting neuroprogenitors with epidermal growth factor (EGF) and ciliary neurotophic factor (CNTF) to obtain glial progenitors, and final differentiation to mature astrocytes by CNTF treatment.

The resulting hESC or hiPSC-derived cells expressed glial fibrillary acid protein (GFAP; 99% of cells), stained positive for astrocyte markers (s100β, glutamate transporters, excitatory amino acid Transporters 1 and 2), and secreted apoE. When treated with T0901317, astrocytoma cells showed a 17-fold increase (over vehicle) in apoE secretion at maximal dose (10μM). Similar treatment with T0901317 increased apoE secretion by 2.3-fold in primary human astrocytes . In stem cell derived astrocytes, the increase was more moderate (hESC: LXR -1.7-fold; hiPSC: LXR-1.4-fold).
Overall, the four astrocyte lines tested showed an increase in apoE secretion when treated with T0901317. However, the amount of apoE secreted differed among the various astrocyte lines. Our data suggest that hPSCs may be potentially developed into a model system to study apoE secretion.

W-3187

PSYCHOSINE ANTAGONIZES CRITICAL SURVIVAL AND PROLIFERATION PATHWAYS IN OLIGODENDROCYTE PROGENITOR CELLS: THERAPEUTIC IMPLICATIONS FOR KRABBE DISEASE

Christopher J. Folts, Nicole Scott, Mark Noble
Dept. of Biomedical Genetics, University of Rochester School of Medicine & Dentistry, Rochester, NY, United States

Lysosomal storage disorders (LSDs) represent some of the most devastating of genetic diseases. In one such LSD, Krabbe Disease, infants who present with the more prevalent early onset form of the disease typically do not survive beyond two years of age and have limited treatment options, most of which are palliative. The severe neurodegeneration and demyelination observed in patients has been attributed to the accumulation of the toxic sphingolipid psychosine, and both the accumulation of psychosine and myelin damage are observed in twitcher mice, a naturally occurring mouse model of the disease. Little attention has been paid, however, to the biology of stem and progenitor cells in these diseases. We found significant reductions in the pool of actively dividing oligodendrocyte progenitor cells (O-2A/OPCs)--cells needed for the generation of myelinating oligodendrocytes during CNS development and for tissue repair under conditions of myelin damage--in major white matter tracts of twitcher mice, even before symptoms are apparent. We also observed in primary O-2A/OPCs that pathophysiological exposure to psychosine in vitro is sufficient to cause cell death, as well as suppression of self-renewing division and differentiation at sublethal concentrations, via the antagonism of critical pro-survival and pro-mitotic signaling pathways. O-2A/OPCs are more sensitive to psychosine than oligodendrocytes, and appear to be the most sensitive cell type thus far identified. To develop possible new therapeutic interventions for Krabbe disease, we have undertaken a high-throughput, high-content screen of FDA-approved compounds and other compounds in primary O-2A/OPC progenitor cells, analyzing multiple parameters through use an adherent cell cytometer (Celigo™) enabling non-invasive, single-cell, FACS-type fluorometric analysis on adherent cells. We have identified 25 candidate protective agents through this multi-parameter screening effort. Although structurally- and functionally-diverse, these compounds share the ability to protect multiple essential cellular processes antagonized by psychosine. In vivo analysis of these compounds is ongoing. In sum, the O-2A/OPCs that are needed for CNS myelination and tissue repair are exquisitely sensitive to psychosine toxicities, both in vitro and in vivo. Using these cells as our starting point, we hope to expand our understanding of the cellular and molecular mechanisms of psychosine toxicity so as to yield novel therapies for the treatment of Krabbe Disease.

DEVELOPMENT AND TRANSCRIPTOME PROFILING OF A NEURONAL MODEL OF LESCH-NYHAN DISEASE

Liam Crapper, Carolina Gigek, Gilles Maussion, Carl Ernst
McGill Group for Suicide Studies, Douglas Research Hospital, Montreal, QC, Canada

Lesch-Nyhan disease (LND) is a rare genetic disorder caused by the disruption of the gene HRPT1. LND has a variety of metabolic and neurological symptoms including crystals in the urine, gout, dystonia, intellectual disability, and chronic self-injury. While the high penetrance of the self-injury phenotype in LND is unique, similar challenging behaviors can be observed in many developmental disorders. The causes of neurological symptoms in LND remain

unknown and to date no treatments have been effective. Human post-mortem studies and animal models of LND show impaired dopaminergic functioning. These studies provide the strongest link between HPRT1 dysfunction and the neurological symptoms of LND; however, dopaminergic impairment alone is not sufficient to cause self-injury. We have developed a novel model of LND using a shRNA knockdown of HPRT in immortalized fetal neural progenitor cells from the ventral midbrain. We have differentiated the progenitors into mature neurons and examined global alterations in gene expression using RNAseq. This study is the first to use high-throughput analysis in a neuronal model of LND, and will provide information vital to the understanding of LND pathogenesis and show pathways which may be involved in the challenging behaviors of other developmental disorders.

A strategy to optimize tissue regeneration is the use of nanofiber matrices containing growth factors (GFs). This strategy is to ensure the correct distribution of stem cells, enhancing their proliferative and differentiation capacity at the injury site, thus preventing the cells from migrating to other locations. The bioavailability of these factors can be obtained by the incorporation of GFs into nanofibers by the electrospinning technique. This aim of this work has been to produce aligned nanofiber matrices with incorporated epidermal GF (EGF) to evaluate their influence on the differentiation of mesenchymal stem cells into neural precursors. Aligned scaffolds with and without EGF were produced by electrospinning, using emulsion consisting of poly(lactic-co-glycolic acid) (PLGA) 15% (w/w), Span-80 0.2%, 1,1,1,3,3,3-Hexafluoro-2-propanol with an aqueous phase containing PBS, albumin (BSA) and 1mg/mL of EGF. The matrices were evaluated for morphology fiber diameter and degradability. Stem cells from human exfoliated deciduous teeth (SHEDs) were cultivated on the scaffolds and were evaluated for the following biological tests: (1) cell adhesion after 6 hr incubation by using DAPI staining, (2) cell viability analyzes after 6, 24, 48 and 72 hours cultivation by MTT assay, (3) cytotoxicity assay on days 4, 7, 14 and 21, through the dosage of the enzyme lactate dehydrogenase (LDH) and (4) neuronal differentiation by phase contrast microscopy, immunofluorescence and electrophysiology. The control group was the cells cultured on wells directly on the culture plates. PLGA/BSA and PLGA/BSA/EGF scaffolds showed aligned fibers, absence of beads, with an average diameter of 537±73nm and 581±79 nm, respectively. There is no difference between the morphology and diameter of both scaffolds ($p<0.05$). The adhesion assay showed that the cells adhere more on PLGA/BSA/EGF than PLGA/BSA scaffolds (p 0.05). Using confocal microscopy, it is possible to observe that SHEDs adhere onto scaffolds, following the same orientation of aligned fibers. The amount of metabolically active cells cultivated, using MTT assay, on both scaffold groups was similar ($p<0.05$). On all days of analyzes both scaffolds were similar to the control group and different from the Triton group, which represents the maximum release of LDH ($p<0.001$). Therefore, this data confirms that the scaffolds are atoxic for the SHEDs. Concerning neuronal differentiation, samples cultivated on both scaffolds and on the control group showed cells with neural phenotype, labeling positively for nestin and GFAP markers. Analyzes are being made to quantify the number of cells positive for each marker in relation to the total number of cells to evaluate the real influence of the alignment of the fibers and EGF in neurogenesis. An increased number of cells

cultivated on PLGA/BSA/EGF, in comparison with other groups, exhibited the capacity to produce sodium current consistent with functional neuronal cells when exposed to neuronal inductive media. Both scaffolds appeared to be good supports for cell adhesion and viability with low cytotoxicity. Scaffolds produced with the incorporation of the EGF showed an improvement in cell adhesion and presence of sodium channels. Therefore, the suggestion is that these matrices can be a possible option for use as biomaterials in neural tissue engineering because they provide stimulus for the cells supporting cellular connectivity.

ASSOCIATION BETWEEN MESENCHYMAL STEM CELLS, FROM HUMAN EXFOLIATED DECIDUOUS TEETH PULP, AND ELECTROSPUN SCAFFOLDS AS A STRATEGY FOR NERVOUS SYSTEM INJURIES

Kerlin Quintiliano[1], Thayane Crestani[1], Davi Silveira[2], Virginia E. Helfer[2], Annelise Rosa[3], Eduardo Balbueno[2], Daniela Steffens[3], Geraldo P. Jotz[4], Diogo A. Pilger[2], **Patricia Pranke**[5]

[1]Hematology and Stem Cell Laboratory, Faculty of Pharmacy; Post-graduate Program in Neuroscience - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [2]Hematology and Stem Cell Laboratory, Faculty of Pharmacy - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [3]Hematology and Stem Cell Laboratory, Faculty of Pharmacy; Post-graduate Program in Material Science - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [4]Post-graduate Program in Neuroscience; Department of Morphological Sciences - Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [5]Hematology and Stem Cell Laboratory, Faculty of Pharmacy; Post-graduate Program in Material Science - Federal University of Rio Grande do Sul; Stem Cell Research Institute, Porto Alegre, Brazil

Scaffolds produced by the electrospinning technique can act as supports for proliferation and differentiation of mesenchymal stem cells (MSCs), providing an alternative for application in regenerative medicine. The scaffold process of nervous tissue regeneration can be improved through the presence of neurotrophic factors such as NGF (Nerve Growth Factor), which plays a central role in the development, maintenance and survival of neurons. This study has aimed to develop scaffolds with aligned and random nanofibers with and without incorporated NGF and to evaluate biological and physicochemical parameters. MSCs were extracted from human deciduous teeth pulp. The following groups were developed and characterized, scaffold with: random nanofibers control (RC), random nanofibers with NGF (RN), aligned nanofibers control (AC) and aligned nanofibers with NGF (AN). The physicochemical analyzes performed were nanofiber morphology and diameter. The biological parameters assessed on the scaffolds were cellular adhesion and proliferation, cytotoxicity, as well as neural differentiation (gene expression for enolase, β-III tubulin and nestin). In all the groups, nanofibers with homogeneous morphology without beads were observed. The nanofiber average diameter was 610±174 nm, 585±109 nm, 537±73nm and 543±128 nm for RC, RN, AC and AN scaffolds, respectively ($P > 0.05$). The adhesion test showed no significant difference between the four groups of scaffolds and the control group (cells cultured directly on well culture plates). This indicates a satisfactory interaction between the cells and the scaffolds, as they showed a similar adhesion pattern to the control. The LDH quantification demonstrated that all groups of scaffolds were similar to the negative control ($P>0.05$), suggesting that they are nontoxic for cells for the 21 days evaluated. All scaffold groups showed similar proliferation rates to the control group at both periods assessed (4 and 7 days). This shows that cell proliferation is sustained when MSCs are cultured on these structures. For neural differentiation analysis, MSCs were cultured on scaffolds or well culture plates for 21 days with neural induction media or with conventional media for MSC culture (control). Gene expression of NSE (Neuron Specific Enolase), β-III tubulin and nestin presented a similar pattern in the MSCs cultivated on the AC scaffold group, cultivated without neural induction media, when compared to the gene expression in the MSCs cultivated with neural induction media seeded directly on well culture plates. This indicates that aligned nanofiber scaffolds could possibly stimulate MSCs for neural differentiation with no other stimuli except the alignment itself. Nestin and NSE expression were up-regulated while β-III tubulin was down-regulated in all scaffold groups not subjected to neural induction. When MSCs were cultured on scaffolds with neural induction media, nestin upregulation was only evident in the AN scaffolds showing a 2.6-fold increase, possibly influenced by NGF presence. MSCs on AC scaffolds treated with neural induction media up-regulated NSE and down-regulated β-III tubulin and nestin expression. This could indicate cellular mechanisms underlying mature neuronal differenti-

ation. This data suggests that the association between MSCs and scaffolds are appropriate candidates for further evaluation as neural tissue engineering strategies using animal models representative of nervous system injuries.

SOX6 REGULATED BY MACROPHAGE MIGRATION INHIBITORY FACTOR PROMTES CELL SURVIVAL AND MAINTENANCE OF MOUSE NEURAL STEM/PROGENITOR CELLS

Shigeki Ohta[1], Aya Misawa[1], Hideyuki Okano[2], Yutaka Kawakami[1], Masahiro Toda[3]
[A]Div of Cellular Signaling, Inst for Adv Med Res, [B]Physiology, [C]Neurosurgery, [1]Keio Univ School of Medicine, Tokyo, Japan

Macrophage migration inhibitory factor (MIF) was identified as a factor that can support the proliferation and/or survival of murine neural stem/progenitor cells (NSPCs) in our previous study. We newly discovered that MIF increases the expression of Sox6, but not Sox1 or Sox2 gene in NSPCs *in vitro*. During neural development, Sox6 was expressed in the ventricular zone of ganglionic eminence (GE) of mouse brains at embryonic day 14.5 (E14.5), cultured NSPCs from E14.5 GE, and NSPCs and neural progenitor cells in the sub-ventricular zone (SVZ) around the lateral ventricle (LV) of the adult mouse forebrain. Retrovirally-expressed Sox6 in NSPCs increased cell viability and the number of primary and secondary neurospheres, thereby supporting cell survival and/or self-renewal ability. The differentiation potential of NSPCs was inhibited by retroviral Sox6 overexpression in NSPCs. Sox6 increased Hes1 and Bcl-2 expression and the phosphorylation of Akt in NSPCs. MIF was shown to activate Stat3 in NSPCs in our previous study. Constitutively-activated Stat3 up-regulated Sox6 gene expression and ChIP analysis showed that MIF increased Stat3 binding to the Sox6 promoter in NSPCs, indicating that Stat3 is a downstream molecule regulated by MIF which promotes Sox6 gene expression. The ability of MIF, which can increase the number of primary and secondary neurospheres was inhibited by Sox6 gene silencing, suggesting that Sox6 may play a key role as a downstream molecule of MIF to support NSPC stemness.

MODULATING THE KYNURENINE PATHWAY TO PROMOTE STEM CELL REPAIR IN MULTIPLE SCLEROSIS.

Chai K. Lim[1], **Simon Jones**[2], Juliana Croitoru-Lamoury[2], Gilles J. Guillemin[1], Bruce J. Brew[3]
[1]Australian School of Advance Medicine, Macquarie University, Sydney, Australia, [2]St Vincent's Centre for Applied Medical Research, The University of New South Wales, Sydney, Australia, [3]Department of Neurology, St Vincent's Hospital, Sydney, Australia

Background: The current therapeutic strategies for multiple sclerosis (MS), such as IFN-β, are of limited efficacy. There exist no treatments that can regenerate or repair damaged myelin and therefore reverse neurological disability in MS. The kynurenine pathway (KP) is a major metabolic pathway that catabolises tryptophan. Tryptophan metabolism is aberrant in a number of inflammatory conditions, including MS. The KP yields several neuroactive downstream metabolites; one of the most biologically significant is quinolinic acid (QUIN). Our group has previously shown QUIN to be neurotoxic and gliotoxic at concentrations of >150nM and >350nM respectively. We have also demonstrated that the KP is fully expressed and functional in both mouse and human mesenchymal stem cells and partially in neural stem cells (NSC). Furthermore the KP is activated by type I & II interferons.
Aim: To explore the potential of modulating the KP to optimise stem cell function therefore promoting remyelination of neurons. We hypothesise that chronic activation of the KP impairs the proliferation and differentiation of NSC.
Methods: Murine NSC were cultured as previously described in our lab and treated with 100 IU/ml IFN-β alone or in combination with 50 nM QUIN. Levels of tryptophan, kynurenine and QUIN were measured in mice with EAE, the widely accepted murine model of MS. Tryptophan and kynurenine were quantified using HPLC. This was expressed as kynurenine:tryptophan (K/T) ratio; a reliable measure of KP activation. Concentrations of QUIN were assessed using GCMS.

Results: Treatment of NSC with IFN-β significantly attenuated their proliferation. Interestingly the addition of QUIN, at a basal concentration of 50 nM, recovered NSC proliferation *in vitro.* Furthermore we found that mice with EAE had an activated KP, as reflected by an increased K/T ratio of 27.14 ± 6.67 in diseased mice compared to 16.6 ± 2.12 in control animals. We also observed that *in vivo* levels of QUIN increased almost two-fold with EAE progression from 129.64 nM ± 18.93 to 227.82 nM ± 54.06 (n=8).
Conclusions: We have shown that NSC are strongly influenced by endogenous KP metabolites and, in the right KP metabolic conditions, can proliferate appropriately. However, in mice with EAE the KP is significantly activated - as measured by an increased K/T ratio and elevated QUIN. Chronic activation of the KP generates neurotoxic levels of QUIN and reduces available tryptophan. This is likely to affect NSC proliferation, differentiation and subsequent remyelination. Results here provide a vital platform for investigating how manipulation of the KP in stem cells could be crucial for the repair of neurons in MS.

ENHANCED REMYELINATING AND IMMUNOMODULATORY EFFECTS OF NEURAL STEM CELLS BY TRANSDUCTION OF NEUROTROPHIN 3

Jingxian Yang[1], Guang-Xian Zhang[2]
[1]Department of Pharmacology, Liaoning University of Traditional Chinese Medicine, Dalian, China, [2]Department of Neurology,, Thomas Jefferson University, Philadelphia, PA, United States

The therapeutic potential of neural stem cells (NSCs) on experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis (MS), has been recently suggested; however, the clinical and pathological improvement is limited. To enhance their therapeutic effect, we in the present study transduced bone marrow derived NSCs (BM-NSCs) with Neurotrophin 3 (NT-3), a potent neurotrophic factor that possesses both neuroprotection and immunomodulation capacities, with a novel Tet-on system to control NT-3 expression. We provide evidence that this approach significantly reduced central nervous system (CNS) inflammation and neurological deficits of ongoing EAE compared to conventional NSC therapy, together with the following advantages: 1) Enhanced BM-NSC proliferation and differentiation of oligodendrocytes and neurons, while inhibited differentiation of astrocytes, thus promoting remyelination and neuronal repopulation, and reducing astrogliosis; 2) Enhanced the anti-inflammatory capacity of BM-NSCs, thus more effectively suppressed CNS inflammation and accelerated endogenous and exogenous remyelination; 3) The easy accessibility of BM-NSCs provides another advantage over brain-NSCs for MS therapy. 4) A Tet-on system can control NT-3 expression as desired. Thus, our study provides a novel approach to break the vicious inflammation-demyelination cycle, and pave the way to an easily accessible, inducible and highly effective therapy for CNS inflammatory demyelination.

HUMAN PLURIPOTENT STEM CELL-DERIVED RADIAL GLIAL LIKE CELLS WITH STABLE REGIONAL IDENTITIES

Laura Ostermann[1], **Julia Ladewig**[1], Franz-Josef Müller[2], Philipp Koch[1], Oliver Brüstle[1]
[1]Reconstructive Neurobiology, Bonn, Germany, [2]Department of Psychiatry and Psychotherapy,, Centre for Integrative Psychiatry,, Kiel, Germany

Key challenges associated with the biomedical application of pluripotent stem cell (PSC)-derived neural cells are their controlled patterning towards distinct regional subtypes and the maintenance of an acquired regional phenotype across multiple passages of in vitro expansion. Previous studies have shown that rosette-type long-term self-renewing neuroepithelial stem cells (lt-NES cells) generated from human PSC undergo gradual posteriorization into an anterior hindbrain phenotype, which might be due to regionalizing effects of the growth factors employed for in vitro proliferation (Koch et al., PNAS 106:3225-30, 2009). During normal CNS development, early NES cells give rise to radial glia (RG) cells, which represent a major source of regionally determined neurons in the embryonic and fetal brain. Here we explored whether PSC-derived neural stem cells (NSC) can be coaxed into RG-like cells

and whether those maintain a stable regional phenotype. Using partially differentiating conditions we were able to establish a NSC population, which exibits features of multipotent neuro- and gliogenic RG cells. These RG-like NSC could be expanded for at least 25 passages and expressed classical NSC markers such as nestin and SOX2 as well as markers typically associated with RG including SOX9, CD44, AQP4 and HOP, while the lt-NES cell markers PLZF, DACH1, ZO-1 and MMRN1 were down-regulated. We next asked whether these cells retain their regional phenotype during in vitro proliferation. To that end we generated RG-like cells from anterior, hindbrain- and spinal cord-patterned rosette-type NSC. We found that RG-like cells with those regional identities continue to express transcription factors appropriate for their positional identity across multiple passages of in vitro expansion while maintaining their differentiate potential into neurons and glia. Thus, conversion into RG-like cells may provide a route for conserving the regional identity of pre-patterned early NSC.

THE 9-O-ACETYL GD3 GANGLIOSIDE AS A SURFACE MARKER FOR NEURAL PROGENITOR CELLS

Marcelo F. Santiago, Fernanda Gubert, Camila Zaverucha-do-Valle, Michelle Furtado, Nicoli Mortari, Bruno Diaz Paredes, Rosalia Mendez-Otero
Instituto de Biofisica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

In adult mammals, neurogenesis persists in two regions: the subventricular zone (SVZ) around the lateral ventricles and the subgranular zone in the hippocampus dentate gyrus. Neural stem cells can be isolated from these areas and are characterized as self-renewable multipotent cells capable of originating neurons, astrocytes and oligodendrocytes. In vitro, these cells can be identified using neurosphere assays, but in vivo their precise identity remains unclear because exclusive markers have not yet been found. The 9-O-acetyl GD3 ganglioside (CD60b) was described as an antigen associated with cellular migration and axonal extension during the development of the nervous system. In the adult, the ganglioside expression is down regulated in most of the brain but remains in a very few specific regions including the SVZ. In this work, we have used magnetic activated cell sorting (MACS) to isolate highly expressing 9-O-acetyl GD3 (CD60b+) cells from the SVZ and we compared the neurosphere formation in CD60b+ and CD60b- populations. We analyzed cells obtained from rats in three different ages: E16, P21 and P90 (adult). In E16, there was no significant difference in neurosphere diameter and in the number of formed neurospheres comparing CD60b+ and CD60b- populations. In P21 and P90 animals, however, the CD60b+ cells were able to form a higher number of neurospheres when compared to the CD60b- population. In P21, the mean neurosphere diameter was also higher in the CD60b+ population.
Furthermore, the phenotypic analysis of the adult SVZ shows that CD60b+ cells do not bind to the PNA (peanut agglutinin) antigen, an excluding marker for NSCs. On the other hand, a subpopulation of CD60b+ cells co-label with the early neuroepithelial intermediate filament Nestin and the neuroblast marker doublecortin.
Based on these results we show that the 9-O-acetyl GD3 ganglioside is expressed in a subset of neural stem cells/progenitor cells in the young/adult SVZ and we suggest that this antigen could be used as a surface marker for isolation/enrichment of adult NSCs.

AN INDUCED PLURIPOTENT STEM CELL MODEL OF NEUROTOXICITY IN PROGRANULIN-DEFICIENT FRONTOTEMPORAL DEMENTIA

Amanda R. Mason[1], Sami Barmada[1], Lauren H. Martens[2], Xialian Xu[2], Aaron Daub[1], Robert V. Farese, Jr[2], Steven Finkbeiner[1]
[A]Gladstone Institute of Neurological Disease, [B]Gladstone Institute of Cardiovascular Disease, [1]Gladstone Institutes, San Francisco, CA, United States

Frontotemporal Dementia (FTD) is the most common dementia in patients younger than 60. FTD patients exhibit behavioral changes or language impairment and progress to death in 6-9 years. No effective treatments exist. Disease symptoms are caused by massive neuronal loss in the frontal and temporal lobes. Among the known ge-

netic causes of FTD, Progranulin (PGRN) haploinsufficiency is one of the most common. The goal of this study is to model neuronal death caused by PGRN haploinsufficiency using cortical neurons derived from FTD patient induced pluripotent stem cells (iPSCs). We present preliminary data that FTD patient fibroblasts can be reprogrammed to iPSCs and then differentiated to neuronal subtypes. Additionally, neurons from mice lacking PGRN exhibit time-dependent neurodegeneration in culture. Exogenous PGRN can rescue neurodegeneration and affects protein clearance pathways in cortical neurons, suggesting that protein homeostasis is critical for maintaining neuronal health in FTD. Future studies will investigate survival and proteostasis phenotypes in iPSC-derived neurons.

PREDICTING THE SUCCESS OF POTENTIAL THERAPEUTICS FOR ALS USING PATIENT-SPECIFIC INDUCED PLURIPOTENT STEM CELLS

Kevin J. Kim, Pamela A. Schein, Lee L. Rubin
Dept. of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States

Amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig's disease, is a fatal neurodegenerative disease affecting 20,000 to 30,000 people in the U.S., with an estimated 5000 new cases every year. Following degeneration of both upper motor neurons from the motor cortex and lower motor neurons from the brainstem and spinal cord, ALS patients undergo loss of motor function and eventually die from respiratory failure within 3 to 5 years from the onset of symptoms. While most ALS cases are sporadic, about 10% of the cases are familial, with mutations in the genes superoxide dismutase 1 (*SOD1*), TAR DNA-binding protein 43 (*TDP-43*), and *C9ORF72*. The only FDA-approved drug for ALS, Riluzole, has, at best, a modest effect, extending lifespan by 3 to 5 months. Therefore, discovering new and better therapeutics is quite important. Yet, despite some mechanistic insights obtained from studying some of the familial cases, past drug discovery attempts have not yielded successful therapies. The recent failures of Olesoxime and Dexpramipexole in Phase III clinical trials reveal the limitation of conventional approaches to finding truly effective ALS treatments. In part, this may be because many clinical candidates that show efficacy in the standard murine models of ALS have failed in the clinic, suggesting that this ALS model is not sufficiently predictive of the response of ALS patients. In addition, the heterogeneity of the disease may complicate the identification of individual patient response to specific agents. To better address these issues, we established a platform using disease relevant cells derived from induced pluripotent stem cells (iPSCs) of multiple patients to serve as the basis for testing potential therapeutics that may rescue the disease types found in patient subpopulations. IPSCs from control and ALS patients were differentiated into enriched populations (>50%) of motor neurons and cultured on mouse glial cells to provide an *in vitro* environment similar to that of the adult CNS. The co-culture was optimized for an automated 384-well assay and quantified using a high content imaging system. Testing of a selection of previous clinical drug candidates showed varying effectiveness of each compound across different lines of ALS motor neurons. In this study, we demonstrate that disease-relevant cells derived from an array of patient-specific iPSCs can be used to test the effectiveness of potential therapeutics towards different forms of ALS and may serve as a valuable and more predictive preclinical model.

RAPID NEUROEPITHELIUM DERIVATION FROM HUMAN PLURIPOTENT STEM CELLS USING FULLY DEFINED, SMALL MOLECULE INHIBITOR INDEPENDENT, AND ADHERENT CULTURE CONDITIONS

Ethan Lippmann, Maria Estevez-Silva, Randolph Ashton
Biomedical Engineering, University of Wisconsin-Madison, Madison, WI, United States

The embryonic neuroepithelium gives rise to the entire central nervous system (CNS) *in vivo*, making it an important tissue for developmental studies and a prospective cell source for regenerative applications. Current protocols for deriving highly pure neuroepithelial cultures from human pluripotent stem cells (hPSCs) *in vitro* consist of either embryoid body-mediated neuralization followed by a selective, manual isolation step or adherent differentiation using small molecules to suppress mesendodermal fates and promote neuroepithelium formation upon passaging.

Herein, we demonstrate a protocol where hPSCs maintained under defined conditions can be differentiated in an adherent monolayer to yield neuroepithelium (>90% $Pax6^+$/N-$cadherin^+$) within 6 days using a medium consisting of only DMEM/F12, sodium bicarbonate, selenium, ascorbic acid, transferrin, and insulin. Using this method, H9 human embryonic stem cells (hESCs) previously cultured under defined conditions routinely reach purities of 99-100% $Pax6^+$ neuroepithelium regardless of whether they are differentiated on an undefined (Matrigel) or defined (recombinant vitronectin peptide) substrate. In contrast, hPSCs maintained on mouse embryonic fibroblasts (MEFs) exhibit much lower neuroepithelial differentiation efficiency using this method (1-40% $Pax6^+$), but transferring the hPSCs to feeder-independent conditions for two passages is sufficient to regain high efficiency. The hPSC-derived neuroepithelium defaults to anterior forebrain identity and can be rapidly patterned to caudal ($HoxB4^+$) and ventral ($Nkx6.1^+$) fates, indicating the neuroepithelium is responsive to lineage patterning cues. Overall, because this protocol is defined and requires no small molecule inhibitors or manual enrichment steps, it can be easily scaled and widely used to derive neuroepithelia from which large quantities of neural cells can be generated for basic and translation research.

TRANSCRIPTOMES OF PROLIFERATING NEURAL STEM CELLS, DIFFERENTIATING PROGENITORS AND NEWBORN NEURONS IDENTIFY LONG NON-CODING RNAS AS NOVEL PLAYERS IN CORTICOGENESIS

Julieta Aprea Perez[1], Silvia Prenninger[1], Tanay Ghosh[2], Dimitra Alexopoulou[1], Elke Wessendorf[1], Andreas Dahl[1], Matthias Groszer[2], Michael Hiller[3], Federico Calegari[1]

[1]DFG–Research Center and Cluster of Excellence for Regenerative Therapies, Dresden, Germany, [2]Institut du Fer à Moulin, INSERM UMR-S 839, Université Pierre & Marie Curie, Paris, France, [3]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Transcriptome analysis of somatic stem cells and their progeny is fundamental to identify the molecular mechanisms regulating the transition from proliferation to differentiation. However, analysing transcriptomes of individual cell types in complex tissues remains a challenge. We generated a RFP/GFP double-reporter mouse line to isolate proliferating neural stem cells, differentiating progenitors and newborn neurons that coexist as intermingled cell populations in the developing cortex. Transcriptome sequencing of these three cell types revealed numerous uncharacterized protein-coding genes and several long non-coding (lnc)RNAs with highly specific and transient expression patterns. Most identified lncRNAs overlapped genes implicated in neurogenesis and shared with them a nearly identical expression pattern suggesting that lncRNAs control neural stem cell differentiation by regulating the expression of cell fate determinants. Finally, we investigated the function of one lncRNA during cortical development and found that it is involved in neurogenic commitment of neural progenitors as well as survival of newborn neurons. Our study provides the most comprehensive and quantitative transcriptome resource during the switch of neural stem from proliferation to differentiation to date and identifies crucial roles of lncRNAs during mammalian corticogenesis.

EFFICIENT NON-VIRAL REPROGRAMMING OF MOUSE FIBROBLASTS DIRECTLY INTO NEURONS

Ellen Amalia Force, Joseph LoTurco
Physiology and Neurobiology, University of Connecticut, Storrs, CT, United States

Mouse embryonic fibroblasts (MEFs) can be directly reprogrammed into neurons with the introduction of three transcription factors, Ascl1, Brn2 and Myt1L, by virally-mediated transgenesis (Vierbuchen et al. 2010). This dramatic type of direct reprogramming, independent of passing through induced pluripotent stem cell stages, presents unique opportunities for exploring control of neuronal identity and the production of neurons from non-neural proliferative cells. In this study, our goal was to test whether induced neurons (iNs) could be produced by trans-

fection of plasmid DNA, bypassing the use of virus and genomic integration of transgenes. We used the liposomal transfection reagent FuGene 6 to transfect Tau-EGFP MEFs with plasmids encoding the three transcription factors, Ascl1, Brn2 and Myt1L. Each expression plasmid contained the ubiquitously active CAG promoter, the cDNA for each respective transcription factor, a polyadenylation signal, and two piggyBac transposon terminal repeats flanking the entire cassette. On their own, PB-pCAG-Ascl1, PB-pCAG-Brn2 and PB-pCAG-Myt1L can be used as episomal expression plasmids, or in combination with a plasmid expressing piggyBac transposase (pCAG-PBase) they can be used to non-virally deliver genomically integrated transgenes. Thus, MEFs were transfected with either BAM alone, or along with pCAG-PBase, to compare the effectiveness of genomically integrated plasmids to episomal plasmids. Five days post-transfection, cells were switched from a fibroblast media to a neural differentiation media. Cells were fixed 7, 10 and 13 days post-transfection, and assessed for the presence of neurons by GFP and β-III-tubulin (Tuj1) expression. Seven days post-transfection few Tuj1+ cells were observed in transfections without pCAG-PBase (~400 Tuj1+ cells/well). The morphologies of these cells at day 7 were generally quite simple, with minimal branching on few processes, but became increasingly more complex with longer and more branched processes by 13 days post transfection. Cells given the pCAG-PBase displayed the same progression of growth and complexity, but were present in approximately double the number as those without pCAG-PBase. At day 7, ~750 Tuj1+ cells/well were observed, and this increased to ~1500 cells by day 13. These results show that MEFs can be directly reprogrammed into neurons by transfection of plasmid DNA and may not require genomic integration of transgenes.

INTERMITTENT ENVIRONMENTAL ENRICHMENT: A NOVEL STRATEGY FOR UNTANGLING THE VARIABLES REGULATING ADULT HIPPOCAMPAL NEUROGENESIS

Catherine-Alexandra Gregoire, David Bonenfant, Adalie Le Nguyen, Anne Aumont, Karl J.L. Fernandes
Universite de Montreal, Montreal, QC, Canada

The hippocampal dentate gyrus (DG) is a rare niche where neurogenesis is preserved throughout life and in which the neurons are implicated in the processes of learning and memory. Remarkably, adult neurogenesis is highly stimulated by environmental enrichment (EE), including variables such as running, environmental complexity, social interactions and stress, which exerts powerful effects on brain physiology. However, the relative contribution of individual EE variables to hippocampal neurogenesis remains a longstanding and poorly understood issue. To help untangle the effects of these variables, we developed a novel experimental paradigm based on intermittent exposure to EE. Adult male CD1 mice were alternated daily between two environments for 4 weeks; by comparing experimental groups in which only one of the two environments differed, individual EE variables could be effectively isolated. We found that intermittent voluntary exercise was sufficient to maximally increase the proliferation, neuroblast and post-mitotic neuron stages of neurogenesis, and to elicit changes in depolarization-associated c-fos expression within the dentate gyrus. Surprisingly, neither social enrichment nor chronically increased levels of stress-associated plasma corticosterone had a persistent impact on neurogenesis. Moreover, environmental complexity (inanimate objects, social enrichment and novelty) effectively buffered corticosterone increases, yet did not affect basal or running-induced neurogenesis. Mouse strain, handling and type of running apparatus were excluded as potential confounding variables. These findings help resolve the effects of distinct variables on adult neurogenesis, and this intermittent EE paradigm will serve as a useful tool for rationally designing more effective and targeted EE approaches.

HNK-1 IDENTIFIES A SUBPOPULATION OF IMMATURE NEURONAL CELLS WITH PROLIFERATION CAPACITY IN THE ADULT MAMMALIAN CAROTID BODY

Veronica Sobrino, Ricardo Pardal
Fisiología Médica y Biofísica, Instituto de Biomedicina de Sevilla (IBiS). Hospital Universitario Virgen del Rocío/CSIC/ Universidad de Sevilla., Sevilla, Spain

The carotid body (CB) has recently been described as a neurogenic niche in the adult mammalian peripheral nervous system (PNS). This peripheral chemoreceptor organ is responsible for the detection and communication of hypoxemia to the central nervous system (CNS). Under maintained low O2 conditions, the CB contributes to physiological adaptation of the organism by increasing three-fold its size, mainly due to an increase in the number of chemoreceptor neuronal cells. This physiological neurogenesis has been partially identified as the result of proliferation and differentiation of a resident population of CB stem cells (CBSCs) within this niche. However, we cannot discard a parallel proliferation of neuronal cells, since different groups have described cell divisions in CB neuronal cells under hypoxic conditions.
By combining immunohistochemistry and flow cytometry techniques, we have found that the human natural killer-1 (HNK-1) glyco-epitope identifies, among other positive cells, a subpopulation of neuronal cells with proliferation capacity and expression of low levels of the differentiation gene, tyrosine hydroxylase (TH). In response to chronic hypoxia, these cells divide and complete differentiation into TH+ (HNK-1 negative) neuronal cells, to contribute to the physiological adaptation of the organ.
Proliferation and differentiation of these neuroblast-like immature neuronal cells is triggered by hypoxia. However, we have found that this activation process needs hypoxia-induced mature neuronal cell exocytotic activity. Blocking of exocytosis with the voltage-gated calcium channel blocker cadmium abrogates the process. Hence, we have demonstrated the existence of a subpopulation of HNK-1+ neuroblast-like cells in the CB, whose activation by hypoxia-induced neuronal activity leads to an increase in the number of neuronal cells in the organ, and therefore to physiological adaptation of the tissue to the persistence of the stimulus.
We are currently testing the functional role of HNK-1 in proliferation and maturation of CB neuroblast-like cells. HNK-1 is a membrane glycoprotein that has been classically described as a neural crest marker during development. More recently, this protein has been proposed to be involved in intercellular adhesion, cell migration and synaptic plasticity in the central nervous system (CNS). Since CB neuronal cells tend to form highly cohesive glomeruli, we hypothesize that HNK-1 is important for new neuronal cells to remain attached to the neuronal glomerulus, to be able to complete differentiation including the formation of synaptic contacts with sensory nerve fibers present in the neuronal glomerulus.
Understanding the physiology of the CB neurogenic niche is crucial not only to learn more about adult neurogenic niches but also to understand the physiopathology of the organ and to improve the use of this tissue for therapeutic purposes.

W-3207

EFFECTS OF EPIDERMAL GROWTH FACTOR ON NEURAL STEM CELLS IN JUVENILE, ADULT, AND OLD RATS AFTER POST-NATAL IRRADIATION

Olle R. Lindberg, Magdalena Rosinski, Georg Kuhn
Institute of Neuroscience and Physiology, University of Gothenburg, Gothenburg, Sweden

Ionizing irradiation is currently one of the primary experimental models for stem cell ablation. The young brain is particularly sensitive to irradiation, in part because of the high prevalence of dividing stem and progenitor cells. Irradiation treatment at a young age can permanently abolish the neural stem cells of the brain. The neurogenic niches of the subventricular zone (SVZ) and the dentate gyrus, not only suffer a reduction of the stem cell pool after irradiation, but the niche itself is permanently altered. With a decreased ability to support proliferation or migration of stem cells, irradiation-induced changes in the neurogenic niche contribute to long-term detrimental effects of irradiation. EGFR (epidermal growth factor receptor) signaling is one of the main characteristics of proliferative neural progenitor cells. EGFR stimulation via EGF infusion results in a drastic restructuring of the SVZ, including induction of extensive proliferation and migration of glial-like progenitors. We have previously described EGF-induced hyperproliferative polyp-formation and dysplastic changes in the SVZ.
The high proliferative capacity of EGF-responsive cells in the naïve SVZ makes them vulnerable to the initial cytotoxic effects of irradiation treatment. However, EGF stimulation via infusion could potentially aid in the recovery of the irradiated stem cell niches, short and long term.

In the current study we are investigating the effects of EGF infusion on the brain in young, adult and old rats after post-natal whole-brain irradiation. Animals received irradiation (8Gy) at post-natal day 9 (P9) and were treated with intracerebroventricular infusion of EGF for two weeks at P21, P80, and one year after irradiation. EGF infusion at P21 and P80 increased the volume of the irradiated SVZ compared to irradiated vehicle controls. The effects of EGF on the irradiated SVZ were overall greater after EGF infusion at P21 compared to P80. In addition, no differences in SVZ volume or proliferation were observed in vehicle-infused P80 animals, indicating a recovery of the SVZ after irradiation. One year after irradiation no significant differences in either proliferation or volume were observed between any of the groups. However, EGF-induced proliferative 'hot spots' in the form of polyps, protruding into the ventricular space, were still found in both sham-treated and irradiated animals. These polyps were observed after EGF infusion at all three different time points, including in animals receiving irradiation. The EGF-induced polyps were surprisingly similar phenotypically and in terms of mitotic activity. The ability of EGF to create a proliferative niche in the, to neurogenesis, unfavorable environments of the aged and the irradiated SVZ is surprising. It could help increase our knowledge on stem cell-niche interactions and how to aid the recovery of neurogenesis after irradiation, and possibly how to slow down the age-related decline in neurogenesis.

W-3208

PICK1 AND PKCα REGULATE JAGGED1 ACTIVATION TO CONTROL NEUROGENESIS

Robert Beattie[1], Antje Grabosch[2], Marion Rukavina[2], Verdon Taylor[1]

[1]Biomedicine, University of Basel, Basel, Switzerland, [2]Molecular Embryology, Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany

During formation of the brain in mammals, neural stem cells (NSCs) transit through sequential periods of expansion, neurogenesis and gliogenesis. Notch ligands are expressed by differentiating progenitors and activate lateral inhibition signals through Notch, maintaining NSCs and blocking transcription of pro-neurogenic factors. Deletion of Delta or Notch from NSCs results in precocious neurogenesis and aberrant brain formation. However, Notch signaling has long been proposed to be bidirectional through ligands such as Jagged1 (Jag1) which is also a type I membrane protein. The molecular mechanisms controlling the transition from stem cell division, where Notch plays a maintenance role, to daughter cell differentiation are poorly understood. Through biochemical and transgenic analysis, we show that PICK1 and PKCα regulate proteolytic activation of the Notch ligand Jag1 to release its intracellular domain (ICD). Nuclear translocated Jag1ICD regulates neurogenesis during cortical development. We propose that Jag1 acts as a signal integrator to modulate neural progenitor fate and drive the onset of differentiation in the developing brain. This model provides a novel paradigm for reciprocal lateral signaling through a Notch ligand to modulate cell fate.

LOSS OF DICKKOPF 1 RESTORES NEUROGENESIS IN OLD AGE AND COUNTERACTS COGNITIVE DECLINE

Désirée R. M. Seib[1], Nina S. Corsini[3], Kristina Ellwanger[2], Christian Plaas[4], Alvaro Mateos[1], Claudia Pitzer[4], Christof Niehrs[2], Tansu Celikel[5], Ana Martin-Villalba[1]

[A]Molecular Neurobiology, [B]Molecular Embryology, [1]DKFZ-ZMBH Alliance, German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]Institute of Molecular Biotechnology (IMBA), Vienna, Austria, [3]Sygnis Bioscience, Heidelberg, Germany, [4]Laboratory of Neural Circuits and Plasticity, University of Southern California, Los Angeles, CA, United States

Adult mammalian neurogenesis takes place in two neurogenic niches in the brain, the subventricular zone of the lateral ventricles and the subgaranular zone of the dentate gyrus. The process of neurogenesis, including the birth of new progenitors, their neuronal differentiation, survival and finally their functional integration into the network, can be influenced by various intrinsic and extrinsic factors within the microenvironment. Specifically, ageing is one factor that leads to a decrease in adult neurogenesis. This age-related decrease in adult hippocampal neurogenesis has been associated with the decline of cognitive functions in the aging population. Although several pathways are known to regulate multiple aspects of adult neural stem cell biology, the molecular basis of the reduction of neurogenesis in the aging hippocampus remains unclear.
Wnt signals are important regulators of adult hippocampal neurogenesis. Here we show that expression of the Wnt antagonist Dickkopf-1 (Dkk1) increases with age in the dentate gyrus and that its loss enhances hippocampal neurogenesis. Conditional deletion of Dkk1 in adult neural stem cells increases their Wnt activity, leading to enhanced self-renewal and a higher production of immature neurons. This Wnt-expanded progenitor population subsequently differentiates into mature glutamatergic granule neurons with increased dendritic complexity.
We also find an increased number of Arc-positive dentate granule cells in Dkk1 mutants, which indicates an increased activity of the neuronal network. Mice that lack Dkk1 show enhanced spatial working memory and memory consolidation, whereby learning itself is not affected. Notably, the performance of middle-aged Dkk1-mutants was set back to the levels exhibited by control young animals. Dkk1 mutant mice also show reduced behavioral despair and increased hedonic behavior. In summary, our findings show that exclusive deletion of Dkk1 in adult neural stem cells increases their levels of Wnt activity and counteracts the age-related decrease in neurogenesis and its associated cognitive decline. Furthermore, it improves affective behavior in the general population.

W-3212

REPROGRAMMING FIBROBLASTS INTO NOCICEPTIVE NEURONS.

Brian Wainger[1], Elizabeth Buttermore[1], Julia Oliviera[1], Naomi Tsujimoto[2], Isaac Chiu[1], Justin Ichida[3], Lee Rubin[2], Kevin Eggan[2], Clifford Woolf[1]

[1]FM Kirby Neurobiology Center, Boston Children's Hospital, Boston, MA, United States, [2]Department of Stem Cell and Regenerative Biology, Harvard Stem Cell Institute, Cambridge, MA, United States, [3]Broad CIRM Center for Regenerative Medicine and Stem Cell Research, Keck School of Medicine of USC, Los Angeles, CA, United States

The study of pain in humans is confounded by subjective interpretation as well as discordance between severity of pain and pathology. Similarly, animal models and heterologous expression studies show marked limitations, and many drugs that appeared promising in animal studies ultimately failed in the clinic. The use of stem cell technology to develop nociceptors offers

a promising approach to modeling pain. Unlike many neuronal subtypes, nociceptors have a very well-defined and specific assortment of receptors and transducers. The most characteristic of these include the tetrodotoxin (TTX)-resistant sodium channel NaV1.8 and the capsaicin receptor, TrpV1. However, production of nociceptors has proven difficult, with little success using traditional morphogen-based approaches and the production of only a low percentage of capsaicin-responding cells using a recent small molecule-based screening approach (Chambers et al, 2012). We have taken a different technique, using forced transcription factor reprogramming of fibroblasts, as has been used to make generic and specific neuronal subpopulations (Vierbuchen et al, 2010; Son et al, 2011). Using TrpV1 or NaV1.8 Cre drivers to generate reporters in mouse embryonic fibroblasts, we have obtained efficient conversion from the fibroblasts into functional neurons that exhibit robust currents in response to capsaicin. The neurons also have TTX-resistant sodium currents with voltage and kinetic properties consistent with NaV1.8. We are currently performing additional characterization using immunohistochemistry, expression profiling, calcium imaging, and patch clamp. In the future, we hope to use the reprogramming technique to evaluate pain and neuropathy phenotypes and to screen for potential analgesics in human cells.

IDENTIFICATION AND CHARACTERIZATION OF RETINAL GANGLION CELLS DERIVED FROM HUMAN INDUCED PLURIPOTENT STEM CELLS

Jason S. Meyer, Manav Gupta, Akshayalakshmi Sridhar
Biology, Indiana University-Purdue University Indianapolis, Indianapolis, IN, United States

Derived from patient samples, human induced pluripotent stem cells (hiPSCs) have the potential to differentiate into any cell type of the body, providing a unique tool for cell replacement, disease modeling, and drug screening. To serve in this capacity, however, hiPSCs must be directed to properly differentiate to the cell type of interest. We have previously demonstrated the ability to differentiate hiPSCs to a retinal lineage, whereupon retinal photoreceptor and retinal pigment epithelium cells were the most abundant cell types produced. The ability to derive retinal ganglion cells (RGCs) from hiPSCs would not only serve as a novel model of human retinogenesis, but would also have profound implications for diseases such as glaucoma or other optic neuropathies. In the current study, we characterize the ability of hiPSCs to generate RGC phenotypes, including those cells expressing the RGC-specific transcription factors Brn3 and Islet-1. Furthermore, treatment of these cells with intrinsic and/or extrinsic factors known to influence the development of specific retinal cell types caused enhanced RGC specification from a more primitive retinal progenitor cell fate. Thus, the data presented within this study demonstrates that under the appropriate conditions, hiPSCs can serve as a reliable source of patient-derived RGCs. These results allow for future studies in which these hiPSC-derived cells may be utilized for studies of a variety of optic neuropathies afflicting the retinal ganglion cell population.

IN VITRO MODELS OF MEDIUM SPINY AND VON ECONOMO NEURON DYSFUNCTION IN FRONTOTEMPORAL DEMENTIA

Kelly M. Haston[1], Hengameh Zahed[2], William W. Seeley[4], Michael C. Oldham[5], Steven Finkbeiner[3]
[A]Roddenberry Center for Stem Cell Biology and Medicine and Keck Program in Brain Cell Engineering, [B]Gladstone Institute of Neurological Disease, [C]Taube-Koret Center for Huntington's Disease Research and the Hellman Family Foundation Program, [1]UCSF Gladstone Institutes, San Francico, CA, United States, [2]The Selective Vulnerability Research Laboratory, UCSF Memory and Aging Center, San Francico, CA, United States, [3]Eli and Edythe Broad Center of Regeneration Medicine and Stem Cell Research, UCSF, San Francico, CA, United States

Frontotemporal dementia (FTD) is the second most common form of early onset dementia after Alzheimer's disease, and is characterized by degeneration of the frontal lobe and other brain regions. FTD has a heterogeneous clinical presentation, including changes in behavior, language, and movement. Large-scale brain networks are affec-

ted, with atrophy most prevalent in network-associated regions. Specific neurons from these regions are selectively vulnerable: in particular, von Economo neurons (VENs), large CTIP2-positive glutamatergic neurons found in layer Vb of the frontoinsula and anterior cingulate cortex. Furthermore, a 25% decrease in striatal volumes relative to healthy controls has also been reported, and the vulnerable population in this region is unknown. We hypothesize that medium spiny neurons (MSNs), GABAergic DARPP32-positive projection neurons with dense spines on their dendrites, which account for >90% of the neurons in the striatum are the afflicted population. The goal of this work is to develop direct reprogramming protocols to derive human in vitro models of FTD in two neuronal subtypes potentially affected in FTD, MSNs and VENs. To accomplish this we have used novel network-level transcriptome analysis from the anterior cingulate cortex, frontoinsula, and striatum to elucidate co-expression modules and "instructive factors" that will drive the in vitro development of MSNs and VENs. We introduce the "instructive factors" into human fibroblasts (FB) or iPSC-derived neural precursor cells (NPCs) derived from both healthy controls and FTD patients. Additional tools include mouse embryonic fibroblasts (MEFs) isolated from a double transgenic mouse model expressing reporters driven by promoters of either the dopamine D1 and D2 receptor, to indicate specific MSN sub-populations. Direct reprogramming of these MEFs will allow us to detect whether different combinations of instructive factors alter the ratio of the derived D1 to D2 expressing MSNs. Analysis includes morphology and immunofluorescence of the neuronal marker MAP2, along with other MSN and VEN specific proteins, to identify successfully reprogrammed cells. However, in collaboration with Sigma Aldrich, we are also developing human iPSC lines with Zinc Finger Nuclease-mediated insertion of fluorescent reporters driven by promoters for genes highly expressed in VENS and MSNs, such DISC1 and DAPRP-32 to allow selection of reprogrammed cells. Development of these reporter lines will allow us to use FACS or laser capture to isolate individual neurons and perform single cell gene expression analysis to determine if the reprogrammed cells are expressing appropriate MSN and VEN gene profiles. Ultimately, using novel robotic microscopy technology, we will perform longitudinal single-cell survival analysis, which will uncover differences in the ability to derive and maintain MSNs and VENs in control and FTD patient cells. Preliminary data suggest overexpression of multiple VEN factors in control FB and NPCs generates the distinctive VEN spindle morphology in Map2-positive cells, while overexpression of MSN factors promotes induced neurons that are both single and double positive for the dopamine D1 and D2 receptors.

MODIFICATIONS IN NEUROSPHERE CULTURE CONDITIONS INFLUENCE NEURONAL DIFFERENTIATION OF CELLS FROM MEDIAL GANGLIONIC EMINENCE

Simone A. Romariz[1], Daisyléia Souza Paiva[1], Maria Elisa Calcagnotto[2], Gabriela Filoso Barnabé[3], Beatriz Monteiro Longo[1]

[1]Neurophysiology, Universidade Federal de São Paulo, São Paulo, Brazil, [2]Biochemistry, Universidade Federal do Rio Grande do Sul, São Paulo, Brazil, [3]Ludwig Institute for Cancer Research, São Paulo, Brazil

Neural stem cells (NSC) from the medial ganglionic eminence (MGE) of the developing brain are responsible for the origin of most inhibitory interneurons in the cortex and hippocampus of the mature brain. *In vitro* these cells preserve the ability to differentiate into inhibitory interneurons. NSC can be cultivated as neurospheres, cell aggregates in suspension, which provide expansion of neural progenitors that differentiate into three cell types: neurons, astrocytes and oligodendrocytes, characterizing an attractive method to study the potential and applicability of NSC for cell replacement therapy in neurological diseases. Here, we tested whether modifications in culture conditions (in the presence of retinoic acid and / or removal of growth factors) influence neuronal differentiation and specification of MGE-derived NSC *in vitro*, enhancing the population of inhibitory interneurons.
MGE from rat embryos (E14) were dissected and the cells were grown as neurospheres in four distinct culture conditions: 1) in the presence of epidermal growth factor (EGF) and fibroblast growth factor-2 (FGF-2) (group E/F); 2) with EGF/FGF-2 plus retinoic acid (RA) (group E/F+RA); 3) only RA (group mitogens free MF+RA) and 4) absence of either EGF/FGF-2 and RA (group MF). In all conditions, the culture medium DMEM/F12, L-glutamine, N2 supplement and antibiotic were present. After 7 days in these culture conditions, neurospheres were plated on an adherent substrate to differentiate for 10 days. The pattern of differentiation was analyzed by immunofluorescence and

flow cytometry using specific markers for neural progenitors (Nestin), astrocytes (GFAP), neurons ([[Unsupported Character - Symbol Font ]]tubIII) and specific inhibitory neurons (Neuropeptide Y – NPY and Parvalbumine - PV).
Neurospheres that grew in the absence of the growth factors EGF and FGF-2 (MF) were smaller when compared to cells cultured in media rich in mitogenic factors (E/F). Also, data from flow cytometry and immunofluorescence indicated that neurospheres cultured only with RA (MF+RA), showed a significantly larger proportion of neurons (23,35% of β-tubIII-positive cells) when compared to the group E/F (2,96%). On the other hand, the media containing EGF/FGF-2 plus RA (E/F+RA) impaired the differentiation of cells, because it increased the number of undifferentiaded neural precursors (40,44% of Nestin-positive cells versus 22,17% E/F, 15,99% MF+RA and 9,39%% MF). Among the inhibitory neuron markers analyzed, the
presence of PV-positive neurons (23,84 %) was higher compared with NPY (43,36%), and a greater percentage of inhibitory neurons was found in the group MF.
Our data suggest that variations in media composition were able to modify the pattern of neuronal differentiation *in vitro*. The absence of EGF and FGF-2 and the addition of retinoic acid affects the neurosphere growing potential and the cell fate by increasing the population of neurons and inhibitory neurons. Cells cultured under specific conditions may be used, in the future, for transplantation into the nervous system aiming diseases that need neuronal replacement.

W-3216

RELATIVE AND COMBINATORIAL EFFECTS OF NICHE-DERIVED FACTORS ON THE BEHAVIOR OF ADULT FOREBRAIN NEURAL PRECURSORS

Sandra E. Joppe, Anne Aumont, Karl J. Fernandes
Universite de Montreal, Montreal, QC, Canada

A complex issue in the study of adult neurogenesis is how neural precursor cells are regulated by the variety of molecules present within their local niche. The subventricular zone of the lateral ventricles is the principal neurogenic niche of the forebrain, and contains a large number of regulatory molecules, such as EGF, FGF, BMP, PDGF, VEGF, SHH and Notch/Delta families. These niche-derived factors have typically been studied individually, and so their relative and combinatorial effects on neural precursor cell behaviors (proliferation, differentiation and survival) remain poorly understood. Here, our objective was to perform a side-by-side comparison of the above niche-derived factors on neural precursor cell cultures isolated from the forebrain of adult mice. First, neurosphere suspension cultures were treated during neurosphere formation and analyzed to assess the effects of individual niche-derived factors on neural precursor cell proliferation and survival. Second, adherent cultures of dissociated neurospheres were treated with these individual factors and analyzed by Western blotting to measure changes in neural precursor cells differentiation. Third, multi-passage experiments were performed to examine long-term effects on neural precursor cell expansion and lineage specification. Finally, combinations of niche-derived factors are currently being tested to determine whether particular factors have additive or dominant effects on neural precursor cell behavior. Preliminary results reveal widely differing impacts of niche-derived factors on the biological properties of cultured neural precursors, and indicate that that particular factors can exert additive or dominant effects with used in combination. We are currently complementing our in vitro findings using in vivo approaches. These experiments will help reveal which niche-derived factors are the most influential regulators of neural precursor cells behavior.

W-3217

THE SPECIFICATION AND MATURATION OF NOCICEPTIVE NEURONS FROM HUMAN EMBRYONIC STEM CELLS

Erin M. Boisvert[1], Shawn E. Hallowell[3], Sandra J. Engle[3], Xue-Jun Li[2]
[A]Genetics and Developmental Biology, [B]Neuroscience, [1]Univ. of Connecticut Health Ctr., Farmington, CT, United States, [2]Genetically Modified Models RCOE, Pfizer Worldwide Research and Development, Groton, CT, United States

It has been estimated that in America alone chronic pain directly affects more than 116 million adults. Nociceptive neurons play an essential role in the sensation of pain as they are responsible for transmitting painful stimuli to the nervous system. However, a major limitation in studies to determine the mechanisms of action as well as potential therapeutics in the human system has been a lack of nociceptive neurons to evaluate. Based on our successful generation of neural lineage cells and spinal progenitors from human embryonic stem cells (hESCs), we investigated the specification and maturation of nociceptive neurons from hESCs by establishing a chemically defined system. Human ESCs were first differentiated into the neural lineage using our differentiation paradigm as previously described. The addition of retinoic acid and bone morphogen factor 4 (BMP4) at specific time points and concentrations yielded a high population of neural crest progenitor cells (AP2a+, P75+). These progenitors were then dissociated and plated onto coated coverslips for terminal differentiation in the presence of neurotrophic factors. Several weeks after differentiation, nociceptive neurons (TrkA+) were generated in the cultures. These mature neurons also stained positive for sodium channel markers (Nav 1.7, Nav1.8) as well as P2X3 which plays a role in the peripheral response to pain. Furthermore, the overexpression of Neurogenin 1 (Ngn1) a key player in the decision of a neural crest progenitor cell to differentiate into a nociceptive neuron, promoted the expression of sensory neuron related genes (Brn3a, TrkA) in the cultures. The optimal time window for Ngn1 expression to generate the highest population of mature nociceptive neurons, as well as the functional capabilities of these cells is under investigation using our recently established Ngn1 inducible hESC system. Overall this study provides insight into the mechanisms underlying the specification of nociceptive neurons from hESCs and it generates a potential tool for high throughput screens of therapeutic agents for pain.

MICROENVIRONMENTAL CHANGES REGULATE NOTCH SIGNALING PATHWAY IN SUBVENTRICLULAR ZONE NEURAL STEM CELLS IN PATHOLOGICAL CONDITIONS.

Manideep Chavali[1], Adan Aguirre[2]

[A]Material Sciences and Engineering, [B]Department of Pharmacological Science, [1]Stony Brook University, Stony Brook, NY, United States

In the normal brain, different cell types and signaling cues create a niche that instruct stem cells to proliferate, migrate and differentiate in order to maintain tissue homeostasis. The unique microenvironment and the cytoarchitecture of subventricular zone (SVZ) maintain neural stem cells (NSCs; type B) and transit amplifying progenitor cells (NPCs; type C) pool size in the adult mammalian brain. Under normal conditions, basal processes of type B cells are in contact with blood vessels and slowly divide to generate type C cells. Thus, the niche sustains cellular homeostasis, but in pathological conditions microenvironmental changes can profoundly affect stem cell behavior, exposing the cells to factors they would not normally encounter. We hypothesized that these factors disturb the natural balance, thus neural stem cells adapt to new conditions in what is believed to be an effort to stop ongoing damage and promote repair. While signaling pathways and related effects of the adult SVZ-niche remain fairly well understood, pathways activated following injury and resulting outcomes are not completely known. Identification of these signaling cues and their outcomes is crucial for developing cell-based strategies to promote functional repair from endogenous stem/progenitor cells. Using animal models of acute subcortical white matter (SCWM) demyelination, we demonstrate that during peak demyelination, Notch signaling in SVZ type B cells is downregulated and the stem cell numbers are decreased. The signaling molecules involved in this pathway were restored back to normal after remyelination. Intriguingly, we also found that in SVZ, vascular network expresses delta 1 (DLL1) ligand, which is required for the activation of notch signaling. During demyelination the number of type B cells contacting the blood vessels were reduced from the ependyma as compared to control conditions. Our data suggests that during demyelination, type B cells lose contact with blood vessels (BVs) and this leads to a loss of self renewal capacity; generating higher number of type C cells, which initiate the remylineation process. Currently we are investigating what signaling cues lead to this contact breakage and the expression of adhesion molecules involved in the anchorage of type B cells to BVs.

W-3221

TRANSFORMATION OF NEURAL STEM CELLS BY NOTCH1 IN VIVO

Sivaraman Natarajan[1], Yaochen Li[1], Emily Miller[1], Michael Taylor[2], Timothy Stearns[1], Roderick Bronson[3], Susan Ackerman[1], Jeong Yoon[4], Kyuson Yun[1]

[1]The Jackson Laboratory, Bar Harbor, ME, United States, [2]Division of Neurosurgery, Program in Developmental and Stem Cell Biology, Hospital for Sick Children, Toronto, ON, Canada, [3]Dana Farber Cancer Institute, Boston, Boston, MA, United States, [4]Maine Medical Center Research Institute, Scarborough, ME, United States

Notch signaling plays an important role in regulating survival, proliferation and maintenance of normal and cancer stem cells in the brain. For example, loss-of-function mutations in Notch pathway genes result in precocious depletion of neural stem cells in the mouse brain, and inhibition of the Notch pathway in neural stem cells and glioma stem cells blocks self-renewal of these cells in vitro. Activation of the Notch pathway results in localization of the intercellular domain of Notch receptors (NICD) to the nucleus, where it binds to transcriptional cofactors to activate many downstream target genes. While activation of the Notch pathway is observed in many human cancers, including brain cancer, it is unknown whether Notch1 activation is sufficient to cause brain tumor formation. To test whether Notch1 has oncogenic function in neural stem and progenitor cells in vivo, we expressed an activated form of NOTCH1 (N1ICD) in the developing mouse brain. N1ICD;GFAP-cre mice were viable but developed severe ataxia and seizures, and died by weaning age. Analysis of transgenic embryonic brains revealed that N1ICD expression induced p53-dependent apoptosis. When apoptosis was blocked by genetic deletion of p53, 30~40% of N1ICD;GFAP-cre;p53+/- and N1ICD;GFAP-cre;p53-/- mice developed spontaneous medulloblastomas. Interestingly, Notch1-induced medulloblastomas most closely resembled the sonic hedgehog (SHH) subgroup of human medulloblastoma. However, when compared to medulloblastomas induced by activation of the SHH pathway (Ptch+/-), Notch1-induced tumors expressed significantly higher levels of genes involved in translational control, chromatin structure, and cellular metabolism, suggesting differences in epigenetic mechanisms of cellular transformation by the two stem cell pathways. In summary, this study demonstrates that elevation of Notch1 activity in neural stem cells can cause cellular transformation when combined with other oncogenic events, such as p53 loss; however, the mechanism of transformation is not through stem cell expansion but rather through induction of DNA damage and epigenetic changes.

W-3222

MICROCEPHALY ASSOCIATED PROTEIN WDR62 REGULATES NEUROGENESIS THROUGH JNK1 IN THE DEVELOPING NEOCORTEX

Zhiheng Xu, Dan Xu, Feng Zhang
Institute of Genetics and Developmental Biology, Chinese Academy of Sciences, Beijing, China

Mutations of WD40-repeat protein 62 (*WDR62*) have been identified recently to cause human MCPH (autosomal recessive primary microcephaly), a neurodevelopmental disorder characterized by decreased brain size. However, the underlying mechanism is unclear. Here, we investigated the function of WDR62 in brain development and the pathological role of *WDR62* mutations in MCPH. We used shRNAs to deplete WDR62 expression in neural progenitor cells (NPCs) via *in utero*
electroporation (*IUE*) in the brain and found that WDR62 knockdown leads to premature differentiation of NPCs. The defect can be rescued by wild-type human *WDR62* but not the five MCPH associated mutant and a mutant that is unable to interact with and activate JNK1. We explored the potential underlying mechanism by which WDR62 affects the coordinated proliferation and differentiation of NPCs. The presence of multiple spindle poles and centrosomes and disturbed mitotic orientation (increase of asymmetric divisions) in WDR62 knockdown NPCs indicates the deregulation of mitosis. In addition, the interaction between WDR62 and JNK1 is essential for WDR62's ability to activate the JNK signaling. JNK1 depletion also leads to premature NPC differentiation and over-expression of JNK1 can rescue WDR62 depletion-incurred different defects. Thus our findings indicate that WDR62 is required for the timing of neurogenesis via JNK1 and provide an insight into the molecular mechanisms underlying MCPH pathogenesis.

W-3223

NESTIN-EXPRESSING HAIR FOLLICLE STEM CELLS FORM THE WHISKER SENSORY NERVE IN LONG-TERM 3D CULTURE

Sumiyuki Mii[1], Jennifer Duong[1], Yasunori Tome[1], Aisada Uchugonova[2], Fang Liu[3], Yasuyuki Amoh[4], Norimitsu Saito[4], Kensei Katsuoka[4], **Robert M. Hoffman**[1]

[1]AntiCancer Inc., San Diego, CA, United States, [2]Department of Biophotonics and Laser Technology, Saarland University, Saarbruecken, Germany, [3]Department of Anatomy, Second Military Medical University, Shanghai, China, [4]Department of Dermatology, Kitasato University School of Medicine, Kanagawa, Japan

Nestin-expressing hair follicle stem cells can differentiate into neurons, Schwann cells, and other cell types. In the present study, vibrissa hair follicles, including their sensory nerve stump, were excised from transgenic mice in which the nestin promoter drives green fluorescent protein (ND-GFP), and were placed in 3D culture supported by Gelfoam®. The whisker nerve stump was regenerated via trafficking nestin-expressing stem cells originating in the bulge of the whisker in Gelfoam® histoculture. The growing nerve fibers had growth cones on their tips expressing F-actin, indicating they were growing axons. The growing whisker sensory nerve was highly enriched in ND-GFP cells which played a major role in its elongation and interaction with other nerves in 3D culture, including the sciatic nerve, the trigeminal nerve, and the trigeminal nerve ganglion. The results of the present report suggest a major function of the nestin-expressing stem cells in the hair follicle is for growth of the follicle sensory nerve. The results also demonstrate the use of Gelfoam® histoculture and hair follicle nestin-expressing stem cells for nerve regeneration.

W-3224

DEVELOPMENTAL CUES INDUCE THE DIFFERENTIATION OF NEURAL CREST DERIVED ORAL MUCOSA STEM CELLS INTO THERAPEUTIC DOPAMINERGIC LIKE NEURONS

Javier Ganz[1], Yael Barhum[1], Tali Ben Tzur[1], Ina Arie[2], Sammy Poor[3], Shareef Araidy[3], Sandu Pitaru[2], Daniel Offen[1]

[A]Neurosciences Laboratory, [B]Oral Biology Dept, [1]Tel Aviv University, Tel Aviv, Israel, [2]Oral & Maxillofacial Dept, Baruch Padeh Medical Center, Poria, Israel

The oral mucosa possesses a high regenerative capacity regardless of the individual's age. Recently, a unique neural crest-like stem cell population (hOMSC) was isolated from the lamina propria of the adult human oral mucosa. In development, neural crest cells are the embryonic origin of the oral mucosa lamina propria, which is formed by migrating neural crest cells from the midbrain in the 4-somite stage. hOMSC exhibit pluripotency and neural crest stem cell markers and differentiate into neuroectodermal lineages. This phenotype is not affected by the donor age. These findings and the midbrain-related lineage origin make the hOMSC population an attractive candidate for cell replacement in Parkinson's disease. The aim of this study was to assess hOMSC ability to differentiate into dopaminergic-like neurons in vitro in response to developmental cues and to test the capacity of this differentiated population to improve symptoms in the hemi-Parkinsonian rat model. The results indicate that hOMSC express constitutively a repertoire of neural and dopaminergic markers: tyrosine hydroxylase (TH), Lmx1a and Nurr1. Exposure of hOMSC to a new differentiation medium consisting of soluble factors known to induce dopaminergic differentiation, induced a neuronal-like morphology in the large majority of the cells, downregulation of stem cells markers and upregulation of the characteristic dopaminergic markers TH, Pitx3, DAT, Nurr1, Otx2 and Lmx1a/b. A significant increase in the dopamine release was observed in DA-differentiated hOMSC (hOMSC-DA). Transplantation of hOMSC-DA into the striatum of hemiparkinsonian rats improved their behavioral deficits as determined by amphetamine-induced rotational behavior, motor asymmetry and motor coordination tests. These improvements were accompanied by the presence of hOMSC-DA expressing TH and increased levels of dopamine in the transplanted hemispheres. These results demonstrate for the first time that soluble factors involved in dopaminergic

differentiation induce hOMSC differentiation into dopaminergic-like neurons in vitro that are capable of improving motor function in hemiparkinsonian rats following their transplantation in vivo.

W-3225

UTILISING PATIENT-DERIVED IPSCS TO UNCOVER CELLULAR PHENOTYPES IN PARKINSON'S DISEASE

Elizabeth M. Hartfield[1], Hugo J. Fernandes[1], Michiko Yamasaki-Mann[1], Helen Christian[2], Jane Vowles[1], Samuel Evetts[1], Kevin Talbot[1], William S. James[1], Michele Hu[1], Sally Cowley[1], Richard Wade-Martins[1]
[A]The Oxford Parkinson's Disease Centre, [B]Department of Physiology, Anatomy and Genetics, [1]University of Oxford, Oxford, United Kingdom

Human induced pluripotent stem cells (hiPSCs) offer the potential to study otherwise inaccessible cell types. Critical to this is the directed differentiation of iPSCs into functional cell lineages. This is of particular relevance to research into neurological disease, such as Parkinson's disease (PD) in which midbrain dopaminergic neurons degenerate during disease progression but are unobtainable until post-mortem. The Oxford Parkinson's Disease Centre has recruited ~900 subjects (PD patients and controls) into its clinical cohort, with a target to collect 2000 subjects over 5 years. We have identified patients carrying mutations in the Leucine-Rich Repeat Kinase 2 (LRRK2) and Glucocerebrosidase (GBA) genes, two of the most commonly mutated genes found in PD. Thus far, 20 LRRK2, 24 GBA, 16 idiopathic PD and 21 control iPSC lines have been generated.
We have differentiated hiPSC lines into midbrain dopaminergic neurons and performed a comprehensive characterisation to confirm dopaminergic functionality by demonstrating dopamine synthesis, release and re-uptake. The neuronal cultures include cells double-positive for tyrosine hydroxylase (TH) and G protein-activated inward rectifier potassium channel 2 (GIRK2), representative of the A9 population of substantia nigra pars compacta (SNc) neurons vulnerable in PD. We used a combination of electrophysiology and calcium imaging to characterise the maturation of the slow autonomous pace-making (2-5 Hz) and spontaneous synaptic activity typical of mature SNc dopaminergic neurons
We then sought to examine autophagy pathways in these neurons using a combination of Western blot, immunocytochemistry and electron microscopy (EM). Initial data indicate increased levels of the lysosomal protein LAMP1 in all PD genotypes and EM analysis in LRRK2 patients indicated an expanded lysosomal compartment, as compared to controls. Increased levels of LC3B were also observed in patient neurons, indicating an upregulation of autophagosome formation. GBA is a lysosomal enzyme and we have found a ~45% decrease in GBA activity in neurons from GBA mutation carriers and a ~20% decrease in GBA activity in idiopathic patient neurons, compared to controls.
hiPSC-derived dopamine neurons from PD patients have perturbations in the cellular pathways responsible for processing damaged proteins and organelles which may implicate a common lysosomal dysfunction in multiple PD aetiologies.

W-3226

NOVEL NEURAL INDUCTION METHOD FOR EFFICIENT GENERATION AND CHARACTERIZATION OF NEURAL STEM CELLS (NSC) DERIVED FROM PARKINSON'S DISEASE (PD) PATIENT SAMPLE IPSC LINES

Marian S. Piekarczyk[1], Tori Sampsell-Barron[1], Kun Bi[1], Spencer B. Hermanson[1], Connie S. Lebakken[1], Laurie J. Reichling[1], Ramya Sundararajan[2], Malini Vangipuram[2], Mohan Vemuri[3], Yiping Yan[3], J. William Langston[2], Birgitt Schuele[2]
[1]Primary and Stem Cell Systems, Life Technologies, Madison, WI, United States, [2]Parkinson's Institute and Clinical Center, Sunnyvale, CA, United States, [3]Primary and Stem Cell Systems, Life Technologies, Frederick, MD, United States

Parkinson's disease (PD) is one of the most common neurodegenerative disorders affecting a million people in the United States alone, with 50,000 Americans being diagnosed with PD each year. The absence of physiologically relevant cellular models for PD represents a major bottleneck for PD research. Novel models are urgently needed to

accelerate the discovery of disease mechanisms and drug targets and for screening purposes which could rapidly translate into a wide range of clinical and therapeutic applications. Patient-specific iPSC-derived cell types have become an attractive tool for disease modeling *in vitro*.
For neuronal differentiation, one commonly used approach is embryoid body (EB) formation followed by neural rosette isolation and expansion. This approach can generate neural stem cells (NSCs) which can differentiate into different neuronal cell types and glia and can be cryopreserved for further maturation. The current limitation is that the process is laborious, inefficient, and the cells usually need to be further purified. To overcome these limitations, we developed a novel neural induction method that allows for the generation of NSCs from iPSCs within 7 to 14 days without the need for EB formation. In this study, we differentiated 4 PD iPSC lines and 2 age-matched control lines into neural stem cells using a novel neural induction/expansion media to differentiate iPSC from an adherent monolayer on different matrices or feeder cells. We demonstrate that the generated NSCs are karyotypically normal, express known NSC markers: Nestin, Sox1 and Sox2. Furthermore, gene expression analysis distinguishes these NSCs from their parental iPSCs and fibroblasts, and clusters them together with control NSCs derived from H9 ESCs.
In summary, the novel neural induction media allows for efficient generation of NSCs from PD patient sample iPSCs and has the potential for large scale NSC generation to be utilized for high throughput/high content screening and drug discovery.

INVESTIGATING THE CONTRIBUTION OF INFLAMMATION TO IDIOPATHIC PARKINSON'S DISEASE USING HUMAN PLURIPOTENT STEM CELLS

Leah Boyer[1], Christopher Tse[1], Benjamin Campbell[1], Beate Winner[2], Zacharias Kohl[2], Kaoru Saijo[3], Christopher K. Glass[3], Juergen Winkler[2], Fred H. Gage[1]

[1]Salk Institute, La Jolla, CA, United States, [2]University Hospital Erlangen, Erlangen, Germany, [3]UC San Diego, La Jolla, CA, United States

Parkinson's Disease (PD) is the most common neurodegenerative movement disorder. Historically, PD has been considered a strictly neuronal disease; however, clinical observations and evidence from animal models suggest inflammation may contribute to disease progression. It remains controversial whether glial activation, and the resulting inflammatory cascade, is a result or a cause of neuronal death. Towards resolving this distinction, we have established cultures of human embryonic stem cell derived dopaminergic neurons, and primary human astrocytes and microglia. These neural cells are used to investigate the glial inflammatory response to extracellular insults, and the neuronal response to pro-inflammatory mediators. We have found that the glial derived pro-inflammatory response can be serially propagated between astrocytes and microglia following a single inflammatory insult. Our human cell based model also establishes the neurotoxic response to a glial derived increase pro-inflammatory cytokines, allowing us to study the inflammatory contribution to the pathological development of PD in a human system. The glial cells are also the foundation of a targeted compound-screening platform for agonists of orphan nuclear receptor Nurr1, whose dual role as both neuro-protective and anti-inflammatory renders it an ideal target for therapeutic intervention in PD. Furthermore, we are differentiating iPS cells from PD patients and controls into neural subtypes to investigate the contribution of inflammation to the progression of idiopathic forms of this degenerative disease. We aim to understand the role of inflammation in PD and identify key molecular events involved at early stages in PD to exploit as potential targets for therapeutic intervention.

W-3228

NOVEL ELECTROPHYSIOLOGICAL PHENOTYPE AND ION CHANNEL COMPOSITION IN IPS NEURONS FROM LRRK2 PARKINSON'S PATIENTS

Leonardo Rodriguez[1], Peter Miu[2], Sally Mak[1], Xin Jiang[2], Faneng Sun[1], Scott Marzano[1], Y. Anne Haung[1], Yanping Li[1], James W. Langston[1], Birgitt Schüle[1]

[1]The Parkinson's Institute, Sunnyvale, CA, United States, [2]Molecular Devices, Sunnyvale, CA, United States

Parkinson's disease (PD) is one of the most common neurodegenerative diseases of aging. There is no cure or effective way to slow disease progression, and the causes of the disease remain obscure. Our goal is to develop a functional experimental tool to study PD using induced pluripotent stem cell (iPSC)-derived dopaminergic (DA) neuron from a patient with LRRK2 parkinsonism. Here, we examine the differences in ion channel expression electrophysiological output, and dopamine release in LRRK2, p.G2019S iPS-derived neurons. We derived iPSCs from patients carrying the most common PD mutation in the leucine-rich repeat kinase 2 (LRRK2) gene, p.G2019S from patient skin fibroblasts using a 4-factor retroviral approach. All iPSCs were characterized for pluripotency, differentiation potential, and were karyotypically normal. Then, we differentiated iPSCs into neural progenitor cells (NPCs) using our published embryoid body approach and dual SMA inhibition. For final neuronal maturation, we differentiated NPCs into dopaminergic (DA) neurons using smoothened agonist (SAG) and fibroblast growth factor 8 (FGF8) for the first 10 days and then further differentiated cells in brain-derived neurotrophic factor (BDNF), glial-derived neurotrophic factor (GDNF) and cyclic adenosine monophosphate (dcAMP) for another 25 days.
For the *electrophysiological studies*, we analyzed the functional profiles of endogenously expressing ion channels, such as voltage-activated inward and outward currents in developing and mature neurons, to evaluate the functional similarity of these cells to primary neurons and used specific K ion channel blocker 4-aminopyramidine (4AP) and the Na ion channel blocker tetrodotoxin (TTX). This was performed on an automated patch-clamp robotic machine. For *assessment of channel composition*, we designed a custom ion channel qPCR array with 48 genes to look at the expression at three time points for DA neuron development, Na channels, K channels and Ca ion channels. Day 0 is the NSC stage before differentiation begins, day 10 is when we switch from our induction media to our maturation media, and the final time point is after full maturity is reached at day 35. Finally, we were assessing dopamine release in these LRRK2 mutant neurons by stimulation of the cells with high KCl and supernatant is measured for DA using HPLC.
Our data show differences between the LRRK2 mutant and control lines. We believe these differences are caused by the LRRK2 mutation. Thus we have a functional PD model-in-a-dish to facilitate drug discovery.

DEVELOPMENT OF HIGH THROUGHPUT FUNCTIONAL SYNAPTIC ASSAYS IN NEURONS DERIVED FROM HUMAN INDUCED PLURIPOTENT STEM CELLS

Pascal Laeng[1], Chris M. Hempel[2], James J. Mann[2], Jeffrey R. Cottrell[2], David J. Gerber[3]
[A]Cellular Pharmacology, [B]MANTRA group, [1]Galenea Corp, Wakefield, MA, United States

Dysfunctions in synaptic transmission play a critical role in many central nervous system diseases. Phenotypic characterization of synaptic dysfunction in human neurons derived from induced pluripotent stem cells (iPSCs) has been limited by the low degree of functional synaptic maturation observed in these cells and the lack of sensitive, high throughput assays that enable efficient screening of synaptic function. We have previously described the development of a high-throughput screening system for identifying modulators of synaptic function (Hempel CM et al., 2011) that can be applied to address these limitations. We have used an upgraded version of the system to measure evoked functional synaptic activities in cultures of human neurons derived from iPSCs. We compared synaptic responses measured in human neuronal cultures to those of rat and mouse cortical neuronal cultures to estimate their degree of functional synaptic maturation and activity in response to various pharmacological agents.
Methods: Post-mitotic human neurons derived from iPSCs (hiPSC-neurons) and primary neuronal cultures isolated from rat or mouse embryonic cortex were seeded in 96-well plates. For analysis of the ability of neurons to initiate action potentials following field stimulation, neurons were loaded with Fluo-4. For analysis of presynaptic function, cultures were infected with an adeno-associated virus (AAV) used to deliver a synaptophysin-pHluorin fusion fluorescent reporter construct (sypHy). Cultures were analyzed between 2 and 8 weeks in vitro on the upgraded MANTRA™ (Multiwell Automated NeuroTRansmission Assay) system or on a fluorescence microscope imaging system. For both systems, fluorescence imaging was performed in parallel with field stimulation trains.

Results: We found that hiPSC-neurons exhibit expected neuronal and synaptic morphology and can be reliably transduced with AAV to express sypHy with no signs of cytotoxicity. Human iPSC-neurons showed robust Ca^{2+} responses to field stimulation trains with voltage thresholds similar to those of rat neurons, suggesting reliable generation of action potentials. The hiPSC-neurons at 3-8 weeks in vitro displayed measureable levels of evoked presynaptic activity on the MANTRA system. Evoked presynaptic responses in hiPSC-neurons show similar frequency-dependent characteristics to those of rodent neurons. Follow- up fluorescence microscopy analysis confirmed the synaptic localization of sypHy signals in hiPSC-neurons. Although presynaptic responses were lower in hiPSC-neurons than in rat primary neuronal cultures, several conditions were found to increase the responses in hiPSC-neurons. Treatment with a compound that modulates presynaptic function yielded similar effects in hiPSC-neurons and rodent primary neuronal cultures. Also, co-culturing hiPSC-neurons with glia resulted in a robust increase in presynaptic responses to field stimulation. Experiments are ongoing to examine whether human astrocytes derived from iPSC can also promote synaptic functionality of human neurons.
Conclusions: The high-throughput capacity of the MANTRA system can be used to quickly characterize the functional and pharmacological properties of synaptic activities in hiPSC-neurons derived from iPSC. Ultimately, our high throughput synaptic assays can be used to characterize synaptic abnormalities in neurons derived from patients and to screen for compounds that restore normal synaptic transmission.

PATIENT-SPECIFIC IPSC-DERIVED NEURONAL CELL MODELS OF HUMAN TAUOPATHIES

M. Catarina Silva, Chialin Cheng, Surya Reis, Wen-Ning Zhao, Steven Sheridan, Tau Consortium, Stephen J. Haggarty
Department of Neurology, Center for Human Genetic Research, Massachusetts General Hospital & Harvard Medical School, Boston, MA, United States

Neurodegeneration is caused by progressive loss of neuronal structure and function in the brain, and has been shown in many cases to be strongly associated with the presence of potentially deleterious protein aggregates. Given the prevalence of neurodegenerative disorders, and lack of effective therapeutics, new approaches for early diagnostics and to identify disease-modifying therapeutic targets are required. Recent advances in human genetics have led to the discovery of genetic susceptibility factors in a growing number of neurodegenerative disorders, including the frontotemporal dementia-spectrum disorders (FTD-s) consisting mainly of FTD, progressive supranuclear palsy (PSP) and corticobasal syndrome. In the case of FTD-s, coding and non-coding genetic variation in the MAPT gene, which encodes the microtubule-associated protein tau, have been identified as the main cause. With the long-term goal of elucidating the molecular basis of tau-associated neurodegeneration in the context of specific FTD-s, we have begun characterizing disease-associated phenotypes using patient-specific induced pluripotent stem cell (iPSC) models. From these FTD-s iPSCs, we have derived expandable, self-renewing neural progenitor cell (NPC) lines and differentiated NPCs. The differentiation of these NPCs provides a system to investigate in cellulo pathology, with tau expression at physiological levels and in the appropriate genetic and cellular context, offering a unique opportunity to focus on the early events of pathogenesis. Our initial findings using western blot analysis and a panel of tau antibodies reveal that while tau levels are almost undetectable in proliferative NPC, expression increases over 5 weeks of differentiation with a predominant expression of 3R form of tau. In FTD-s cells, tau reached higher levels and at an earlier time-point relative to control cells, over the course of neuronal differentiation. Overall, our findings support the relevance of using patient-derived iPSCs and neuronal cells for investigating the molecular mechanisms of FTD-s. Characterization of tau post-translational modifications, aggregation and processing into lower molecular weight fragments is on-going. In addition, we are pursuing the development of high-content, image-based assays that can support high-throughput screening of chemical, RNA interference (RNAi), and ORFeome libraries for modifiers of tau phenotypes, including clearance through autophagy pathways. We anticipate that expansion of this iPSC-based platform will enable the discovery and validation of effective disease-modifying, targeted therapeutics, with relevance for a large group of tauopathies and other dementias, such as Alzheimer's disease.

W-3233

ADVANCING TRANSLATIONAL NEURAL REGENERATIVE MEDICINE BY USING PIG INDUCED PLURIPOTENT STEM CELLS

Amalia Gallegos Cardenas, Kai Wang, Erin T. Jordan, Rachel C. West, Franklin D. West, Jeong-Yeh Yang, Steven L. Stice
Animal and Dairy Science, University of Georgia, Athens, GA, United States

The generation of pig induced pluripotent stem cells (iPSCs) opened the possibility to evaluate allograft and autologous neural cell therapy as a viable option for human patients. However, it is necessary to demonstrate whether pig iPSCs are capable of in vitro neural differentiation similar to human iPSCs in order to perform in vitro and in vivo comparative studies and to determine optimum differentiation conditions for forming functional neural therapeutics. A recent report from our group demonstrated that pig iPSCs can differentiate in vitro into neuron and glial cells and were capable of in vitro directed differentiation into motoneurons in the presence of motoneuron signaling factors. Multiple labs have generated pig iPSCs that have been characterized using pluripotent markers such as SSEA4 and POUF51. However, correlations of pluripotent marker expression profiles among iPSCs lines and their neural differentiation potential has not been fully explored. Because neural rosettes (NR) are composed of neural stem cells, our goal was to demonstrate that NR from pig iPSCs can be generated, isolated, and expanded in vitro from multiple porcine iPSCs lines similar to human iPSCs and that the level of pluripotency in the starting porcine iPSCs population (POUF51 and SSEA4 expression) could influence NR development.
Three lines of pig iPSCs from different donors, M1 (porcine mesenchymal stem cells), F1 (porcine fibroblast cells) and one sub-line from F1 (SLF1) were cultured on matrigel coated plates in mTeSR1 medium and passaged every 3-4 days. For neural induction, pig iPSCs were disaggregated using dispase and plated. After 24 hours, cells were maintained in N2 media (77% DMEM/F12, 10 ng/ml bFGF and 1X N2) for 15 days. To evaluate the differentiation potential to neuron and glial cells, NR were isolated, expanded in vitro and cultured for three weeks in AB2 medium (AB2, 1X ANS and 2mM L-Glutamine). Immunostaining assays were performed to determine pluripotent (POU5F1 and SSEA4), tight junction (ZO1), neural epithelial (Pax6 and Sox1), neuron (Tuj1), astrocyte (GFAP), and oligodendrocyte (O4) marker expression.
In this study we showed that all pig iPSCs were negative for NR markers Pax6 and Sox1. However, Line F1 ($POU5F1^{high}$ and $SSEA4^{low}$) showed a high potential to form NR in comparison to the other 2 lines M1 ($POU5F1^{low}$ and $SSEA4^{low}$) and SLF1 ($POU5F1^{low}$ and $SSEA4^{high}$) upon differentiation. The NR immunocytochemistry results from Line F1 showed the presents of Pax6+ and Sox1- NR cells at day 9 post-neural induction and that ZO1 started to localize at the apical border of NR. At day 13, NR cells were Pax6+ and Sox1+, and ZO1 was localized to the lumen of NR. After isolation and culture in vitro, NR cells expressed transcription factor OTX2 through 2 passages, but was not detected in later passages. However, rosette cytoarchitecture was present up until passage 7 and were still Pax6+/Sox1+. NR at passage 2 were cryopreserved and upon thaw showed normal NR morphology and were Pax6+/Sox1+. To characterize the plasticity of NR, cells were differentiated. Tuj1 expression was predominant after differentiation indicating a bias towards a neuron phenotype. These results demonstrate that F1 pig iPSCs ($POUF51^{high}$ and $SSEA4^{low}$) have a high potential to form NR and neural differentiation parallels human iPSCs neurulation events. Porcine iPSCs should be considered as a large animal model for determining the safety and efficacy of human iPSCs neural cell therapies.

ELUCIDATING THE DEVELOPMENTAL MATURITY OF PLURIPOTENT STEM CELL DERIVED NEURAL PROGENITOR CELLS

Kimberly Loo, Xavier Gaeta, Michaela Patterson, William E. Lowry
Molecular, Cellular and Developmental Biology, University of California, Los Angeles, Los Angeles, CA, United States

Human pluripotent stem cells (hPSCs) have the potential to differentiate into many cell types, yet it is not known how similar the process of PSC in vitro development reflects the in vivo development. Recent work from the Lowry lab has found that both human embryonic stem cells and human induced pluripotent stem cells make cells that

are more similar to cells found only very early in fetal development. From this work, the Lowry lab identified a set of 88 genes whose expression appears to distinguish mature tissue derived cells from those generated from hPSCs. Among some of the differences observed between hPSC progeny and their respective natural counterparts are genes thought to only be expressed in early embryos, such ¬¬as LIN28, DPPA4, and TCF7L1. Furthermore, a second set of "maturity/specification" genes fails to be properly induced during in vitro differentiation. Both findings suggest incomplete specification or maturity of the PSC-derivatives. We hypothesize that gene manipulation experiments will be able to bring PSC derivatives closer to their natural counterparts on a global transcriptome level.
In attempts to make PSCs that more accurately reflect their natural postnatal tissue derived counterparts, experiments were performed using lentivirus infections aimed to overexpress several maturation/specificity genes in PSC derived neural progenitor cells (NPCs). Real-time reverse-transcription PCR (qRT-PCR) was used to quantify gene expression levels at the RNA level, while immunofluorescence was used to quantify expression levels at the protein level. Further, a functional assay was performed to evaluate the effects of the gene manipulations by determining whether the cells have a higher propensity to generate neuronal or glial cells.

W-3235

MODELING HEREDITARY SPASTIC PARAPLEGIAS USING HUMAN PLURIPOTENT STEM CELLS.

Kyle Denton[1], Ling Lei[1], Jeremy Grenier[1], Craig Blackstone[2], Xue-Jun Li[1]
[1]Department of Neuroscience, University of Connecticut Health Center, Farmington, CT, United States, [2]Cell Biology Section, Neurogenetics Branch, National Institute of Neurological Disorders and Stroke, Bethesda, MD, United States

Hereditary spastic paraplegias (HSPs) are a heterogeneous group of genetic disorders that result in progressive lower limb spasticity due to a length-dependent degeneration of axons, most severely affecting corticospinal motor neurons. Affected neurons display "dying back" axonopathy, particularly in the spinal cord, resulting in lost lower motor neuron innervations which produce lower limb spasticity and weakness. Although there are 55 distinct genetic loci where mutations are associated with HSP, one form, SPG4, accounts for nearly 50% of all cases of HSP. Autosomal dominant SPG4 mutations affect the SPAST gene, which encodes the microtubule-severing ATPase spastin. The lack of a human neuronal model of SPG4 has led us to generate human induced pluripotent stem cells (iPSCs) from affected patients using both the Cre-excisable STEMCCA lentiviral system and an episomal reprogramming method, which avoids transgene integration. These iPSCs expressed the standard set of pluripotency markers and maintained a normal karyotype after many passages. Using a well-established differentiation protocol, we found that the HSP iPSCs were able to differentiate into telencephalic glutamatergic neurons with similar efficiency as control iPSCs. Importantly, we found that the SPG4 neurons displayed a significant increase in axonal swellings after 6 weeks of differentiation (SPG4 = 0.824±0.238 swellings per 100 µm axon vs. control = 0.016±0.014 swellings per 100 µm axon), which previous studies have shown to be caused by microtubule-based transport defects. In addition, these swellings stain strongly for mitochondria and tau, suggesting the accumulation of axonal transport cargoes in these regions. This finding is in agreement with two knock out mouse models that lack spastin expression, and provides evidence that these iPSCs can be used to model HSP in vitro. To support these findings we have also generated four Tet-On spastin-inducible H9 embryonic stem cell lines that allow the overexpression of several spastin isoforms fused to GFP, including an ATPase-defective form of spastin (K388R). Cells expressing K388R spastin display normal neural differentiation; however, the localization of the mutant spastin is perturbed at all stages of differentiation observed, with strong colocalization with microtubules. In cells expressing a mutant M1 spastin isoform, we observed a significant decrease in the percentage of motile mitochondria. Overall, this study provides insight into the usefulness of a human stem cell model of SPG4, which should prove valuable for future studies aimed at dissecting the mechanism of axonal degeneration in this neurodegenerative disease.

EXOGENOUS ADULT MOUSE POST MORTEM NEURAL PRECURSORS PROMOTE FUNCTIONAL RECOVERY IN A MOUSE MODEL OF PARKINSON DISEASE AND DIFFERENTIATE IN TH-POSITIVE NEURONS

Stephana Carelli, Andrea Raspa, Toniella Giallongo, Anna Maria Di Giulio, Alfredo Gorio
Health Sciences, University of Milan, Milan, Italy

Parkinson's disease is the second most common neurodegenerative disease, after Alzheimer's disease, and the most common movement disorder. Drug treatment and deep brain stimulation can ameliorate symptoms, but the progressive degeneration of dopaminergic neurons in the substantia nigra eventually leads to severe motor dysfunction. The transplantation of stem cells has emerged as a promising approach to replace lost neurons in order to restore dopamine levels in the striatum and
reactivate functional circuits. Post Mortem Neural Precursor Cells (PM-NPCs) are a subclass of SVZ-derived neural progenitors, capable of surviving hours after donor death. The *in vitro* differentiation yields more
neurons (about 30-40%) compared to regular NPCs. Recently from a transgenic mouse strain expressing green fluorescent protein (GFP) under the promoter C of the ubiquitin gene (C57BL/6-Tg(UBC-GFP)30Scha/J) we isolated PM-NPCs-GFP, from mice at 6 hours after death (T6). The potential of PM-NPCs in terms of replacement therapy was investigated in a mouse model of Parkinson disease. The degeneration of dopaminergic neurons was obtained with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine
(MPTP) at the dosage of 36 mg/kg intraperiteoneally. Then the lesion was
stabilized by a second injection (i.p.) of the drug at the dosage of 20 mg/kg. 1x 10^5 of PM-PCs-GFP were administered to C57/BL mice by stereotaxic
injection unilaterally in the striatum 3 days after the second MPTP administration. The effects of transplanted cells were determined by means of performance tests aimed at detecting behavioral improvements. In order to perform histology studies aimed at investigating the fate of transplanted precursors after transplantation, animals were perfused 2 weeks after transplantation. Our results show that animals treated with T6 GFP-PM-NPCs had a remarkable improvement of parameters measured
by means of both horizontal and vertical grid tests (wall time, forepaw fault
and time required to grab on the grids while turning and climbing down) starting with the third day after transplantation. These improvements were
very significant and the average values were close to control. This was maintained throughout 2 weeks of experimental observation. By means of immunofluorescence staining we observed that the majority of transplanted
T6 GFP-PM-NPCs were vital and able to migrate ventrally and caudally from the injection site lengths as far as 1000 microns into the striatum, and could reach the ipsilateral and contralateral substantia nigra pars compacta. Moreover, morphological analysis revealed that transplanted cells in the striatum can differentiate into dopaminergic (40%), cholinergic (40%), and gabaergic neurons (20%). These data suggest how these cells may represent a liable source for cellular therapy in neurodegenerative disorders such as Parkinson Disease

W-3237

GENERATION OF AN INDUCIBLE MODEL OF STRIATAL ENRICHED PHOSPHATASE EXPRESSION IN HUMAN INDUCED PLURIPOTENT STEM CELL DERIVED NEURONS

Sandra J. Engle[1], Jeffrey Stock[1], Thao Nguyen[2], Thomas Lanz[2]
[1]Pharmacokinetics, Dynamics and Metabolism, Pfizer, Groton, CT, United States, [2]Neuroscience Research Unit, Pfizer, Cambridge, MA, United States

Striatal enriched phosphatase (STEP, PTPN5) is a brain-enriched tyrosine phosphatase. Activation of STEP promotes the internalization of NMDA and AMPA receptors and the inactivation of ERK, p38, Pyk2 and Fyn, key molecules involved in synaptic strengthening and memory formation. STEP knock-out mice show increased phosphorylation of NMDA and AMPA receptor subunits as well as ERK and enhanced performance in hippocampal-dependent learning and memory tasks. Dysregulation of STEP has been associated with neurological disorders including schizophrenia, Alzheimer's disease, Huntington's disease and Fragile X. It has been suggested that inhibition of STEP may mitigate

symptoms associated with these disorders. To facilitate the study of STEP in neuronal function, we have generated human induced pluripotent stem cells (hiPSC) carrying a loxP-flanked target site in the AAVS1 locus (PPP1R12c). Recombinase-mediated cassette exchange was used to introduce a tet-inducible STEP containing a point mutation in the catalytic domain (C300S). $STEP_{(C300S)}$ continues to bind substrates but, lacking enzymatic activity, cannot dephosphorylate and disengage them. The “trapped” substrates can be immunoprecipitated and evaluated in an effort to identify novel STEP substrates and to determine how these substrates change with differentiation from neural progenitors to mature neurons.

W-3238

FIBRIN-BASED NICHE SUPPORTS IN VITRO DIFFERENTIATION OF NEURAL PROGENITORS FROM HUMAN PERIPHERAL BLOOD AND IN VIVO SURVIVAL OF TRANSPLANTED CELLS IN RATS

Tara S, Lissy K. Krishnan
Thrombosis Research Unit, Biomedical Technology Wing, Sree Chitra Tirunal Institute for Medical Sciences & Technology, Poojappura,Trivandrum, India

Adult stem cells are being extensively studied as autologous source in regenerative medicine. Rare presence of NPC among the heterogenous and multipotent monocyte population necessitates further commitment to neural lineage and expansion by *in vitro* culture to obtain sufficient numbers of pure NPCs population for transplantation which may
be a promising strategy for the treatment of spinal cord injury (SCI). There
are challenges associated with cell transplantation including poor cell homing and survival at the injured site due to unfavorable mileu which
necessitates a good cell carrier for successful transplantation. The hypothesis of this study is that a fibrin-based biomimetic niche may support *in vitro* proliferation and lineage commitment of circulating NPCs, and the same may act as promising cell carrier for successful transplantation.
After experimenting with different concentrations of matrix molecules, the selected composition showed induction of human and/or rat NPCs to
neurons. The essential niche components identified were: adhesive proteins like fibrin, fibronectin, laminin and gelatin; growth factors in hypothalamus extract and platelet growth factor; hyaluronic acid and the medium supplemented with fetal calf serum, growth factors, retinoic acid and potassium chloride (KCl). The peripheral blood mononuclear cells (PBMNCs) were isolated from human and/or rat blood (Inbred Wistar strains) and the non plastic-adherent cells were cultured on the composed matrix for 10-15 days. Cells were analyzed at different time intervals for the expression and distribution of neural specific markers using immuno cyto chemistry. For *in vivo* experiments, contusion type SCI model was created using an impactor with ~150 dyne cm^{-2} force. The fluorescent tagged lineage committed cells (~$75x10^2$/site) mixed with fibrinogen composite was clotted at the site of injury using thrombin and cells suspended in culture medium was delivered in control sites. Basso, Beattie and Bresnahan (BBB) scoring was done weekly to evaluate the locomotor recovery and fluorescent imaging to visualise cell survival. Tissue sections were collected after 1 week and 4 weeks after transplantation for histological analysis.
Neural-like cells (NLCs) were observed in the standardized niche in human PBMNC culture from day5 but for rat PBMNC, NLCs were seen by day 10. The cells expressed neural progenitor marker nestin and the intermediate neural marker beta-tubulin3. Synaptophysin was expressed by a low percentage of cells at day 14. A small percentage of the cells were also positive for Map-2, a mature neuronal marker and GFAP, a glial marker. *In vitro* proliferation studies indicated that these NLCs were non-proliferative. The lineage commitment was independent of the presence of retinoic acid. Microscopically, cell to cell communication was observed to be improved upon KCl addition. Ninety percent of animals showed clinical signs of SCI, and improvement in BBB score was evident in most animals. Survival of transplanted cells was significant in test animals as compared to controls. Histological sections of the tissue collected from injured site at 1 week was comparable to that collected at 4 weeks, suggesting the prolonged survival but poor proliferation of transplanted cells.

Conclusion: Fibrin based niche supported *in vitro* differentiation of NPC from PBMNC and *in vivo* homing and survival of transplanted NLCs. So the bio mimetic fibrin matrix acts as a good cell delivery vehicle for SCI.

W-3241

MECP2E1 ISOFORM MUTATION CAUSES SYNAPTIC DYSFUNCTION IN RETT SYNDROME PATIENT IPSC DERIVED NEURONS

James Ellis, Ugljesa Djuric, Aaron Y.L. Cheung, Wenbo Zhang, Alina Piekna, Jason Hendry, P. Joel Ross, Peter Pasceri, Dae-Sung Kim, Michael Salter
Hospital for Sick Children, Toronto, ON, Canada

Rett Syndrome (RTT) is caused primarily by mutations in the X-linked MECP2 gene that affect two alternative transcripts encoding distinct MECP2e1 and MECP2e2 proteins. MECP2e1 is more highly expressed in the brain and rare patient mutations that affect only MECP2e1 protein have been described, but the cellular consequences of MECP2e1 mutation are unknown. We report the first MECP2e1-specific mutant cellular disease model by generating induced Pluripotent Stem Cells (iPSCs) from a RTT patient with a heterozygous 11bp deletion in exon 1.
We isolated four RTTe1-iPSC lines from this patient and differentiated them into neurons for phenotyping. The iPSC and neurons derived from them retain an inactive X-chromosome and express only the mutant MECP2 allele, indicating that MECP2 is not subject to erosion of X-chromosome inactivation over time as the iPSCs are passaged. Single cell Fluidigm expression arrays demonstrate that roughly 80% of the differentiated cells are mature neurons of predominantly cortical origin, and that MECP2e1 mutation does not affect neuronal fate choices in comparison to control neurons. Efficient differentiation required modified protocols for each line but consistently revealed a reduced soma size. These RTTe1 neurons exhibit subtle expression changes to a subset of MECP2 target genes. Infection of iPSC derived neural progenitor cells with a MECP2e1 isoform-specific lentivirus vector under the control of an internal mouse Mecp2 promoter rescues the soma size defect in a cell autonomous manner. Thus MECP2e1 mutation causes cell morphology and gene expression changes that may affect neuronal function.
We performed whole-cell patch-clamp recordings in RTTe1 and control neurons to investigate the cellular basis of RTT phenotypes. Mutant neurons had higher input resistance and exhibited decreased numbers of action potentials evoked by injecting depolarizing currents. Evoked action potentials in mutant neurons also had smaller amplitude and prolonged half duration that may be attributed to a significant decrease in voltage-gated Na+ currents. Furthermore, RTTe1 neurons had dysfunctional synaptic activity with decreases in both frequency and amplitude of miniature excitatory postsynaptic currents. Our findings demonstrate that MECP2e1 mutation causes dysfunction of Na+ channels and synaptic activity in addition to a cell autonomous soma size defect. These observations highlight that lack of MECP2e1 alone causes many RTT phenotypes in human neurons.

W-3242

RHOA REPRESSES PROLIFERATION IN THE CEREBELLUM AND IS A POTENTIAL TUMOUR SUPPRESSOR IN MEDULLOBLASTOMA FORMATION.

Dominik Herzog[1], Joao B. Relvas[2], Ueli Suter[3], Verdon Taylor[1]
[1]Department of Biomedicine, University Basel, Basel, Switzerland, [2]Glial Cell Biology, IBMC, Porto, Portugal, [3]Institute of Cell Biology, ETH, Zürich, Switzerland

We and others have recently shown an important role for the small GTPase RhoA in regulating proliferation and apical anchoring of neural stem cells in the developing mouse nervous system. The expression of RhoA negatively correlates with the grade of malignancy in gliomas and RhoA has been described to influence proliferation and migration in different glioma cell lines. However, the involvement of RhoA in postnatal cerebellar development and cerebellar tumour formation has not been addressed to date. We found that conditional ablation of RhoA from Nestin::Cre expressing radial glia resulted in viable mice that displayed disturbed cerebellar structure and postnatal hyperplasias that resemble early stage medulloblastomas. These RhoA conditional knockout (cKO) mice have increased proliferation in the external germinal layer (EGL) of the cerebellum as well as in granule cell precursor

(GCP) primary cell cultures in vitro supporting a cell autonomous function for RhoA. In the EGL of cKO mice the hyper-proliferation is accompanied with increased cell numbers resulting in tumour-like growths on the surface of the cerebellum. Furthermore mitotic GCP are not restricted to the outer EGL and invade the meningeal space forming ectopic hyperplastic tissue. Although proliferating cells are observed in these ectopic areas of EGL in the cKO, at ages where the EGL and proliferation in wild type mice is no longer present, the mutant cells are not transformed as they exit the cell-cycle and differentiate without forming tumours. In primary cell culture, GCPs from cKO mice have an increased basal proliferation rate in the absence of the mitogen Shh and this basal proliferation is insensitive to Shh inhibitors. In addition, the RhoA-deficient GCPs display enhanced responsiveness to Shh in vitro. We have preliminary evidence that the effect of RhoA to repress GCPs proliferation and regulate Shh activity is, at least partially, via regulation of ROCK. Taken together, RhoA represses proliferation in the cerebellum potentially by interacting with the Shh signalling pathway. Loss of Rho/ROCK signalling in the cerebellum leads to pre-neoplastic transformation of GCP which may make them more susceptible to medulloblastoma formation showing a potential role for RhoA as a tumour suppressor.

W-3243

SENSORY NEURON TRAJECTORIES ARE REGULATED BY AN RNA-BINDING PROTEIN THAT MODIFIES EXPRESSION OF A NEUROTROPHIN

Shinsuke Shibata, Hideyuki Okano
Department of Physiology, Keio University, School of Medicine, Tokyo, Japan

Segregation of touch and pain sensation pathways into the spinal cord is regulated to assure no cross-talk but it is not known how. Several lines of evidence support the idea that control of the release of neurotrophic factors is important for establishing normal trajectories for sensory axons. Here we demonstrate that the developmental release of one such factor is controlled by the RNA-binding protein Musashi2 (Msi2), known as one of the stem cell markers. This transient up-regulation by Msi2 plays a critical role in spinal mechanoreceptive network projection because the major msi2 knockout mice phenotype is hypersensitivity to touch sensation due to abnormal projection of mechanoreceptive axons into the pain receptive area. Thus, appropriate recognition of touch and pain as distinct sensations requires the embryonic surge of a neurotrophic factor under post transcriptional control of a RBP. We propose a novel regulatory mechanism for the segregation of sensory perception.

W-3244

ESTABLISHING AN IN-VITRO HUMAN SCHIZOPHRENIA MODEL FOR THE ANALYSIS OF DISEASE-ASSOCIATED NEURONAL SUBTYPES

Ralda Nehme[1], Ali Hussain[2], Karlijn van der Ven[3], Jurgen Del-Favero[3], Rolf Adolfsson[4], Annelie Nordin[4], Roy Perlis[5], Christine T. Finn[7], Raju Kucherlapati[8], Stephen J. Haggarty[6]
[1]Stanley Center for Psychiatric Research, Broad Institute of Harvard and MIT, Cambridge, MA, United States, [2]Department of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States, [3]Department of Molecular Genetics, VIB, Flanders, Belgium, [4]Faculty of Medicine, Department of Clinical Sciences, Psychiatry, Umea University, Umea, Sweden, [A]Psychiatry Center for Experimental Drugs and Diagnostics, [B]Department of Neurology, [5]Harvard Medical School and Massachusetts General Hospital, Boston, MA, United States, [6]Psychiatry, Dartmouth-Hitchcock Medical Center, Lebanon, NH, United States, [7]Department of Genetics, Harvard Medical School, Boston, MA, United States

Schizophrenia is a disabling neuropsychiatric disorder that affects 1% of the world population. Despite its high prevalence, significant financial burden and high heritability (80%), the cellular and molecular mechanisms underlying schizophrenia are poorly understood. The strongest known risk factor for schizophrenia is a heterozygous deletion at human chromosomal locus 22q11.2 (22q11.2 deletion syndrome, 22qDS), affecting a region containing approximately 60 genes, many which regulate brain development.

Evidence from several sources such as brain imaging analyses and human post-mortem studies suggest that schizophrenia is a disorder of cortical neuron dysfunction, in particular layer III pyramidal projection neurons, characterized by thinning of the cerebral cortex and reduced dendritic spine density. Furthermore, genome-wide association studies (GWAS) implicate several genes involved in synaptic structure and function. Strikingly, mice carrying a deficiency in the region orthologous to 22q (mouse chromosome 16) exhibit defective neuronal differentiation and network formation. However, human prefrontal cortex differs enormously from the mouse, underscoring the need for human cellular models. Thus, we chose to study schizophrenia by developing and analyzing neurons and neural networks in cells from individuals with 22qDS. In order to generate a human in vitro system to recapitulate neuronal development, we obtained skin fibroblast from three patients with 22q11.2 deletion syndrome, and three unaffected individuals. We used the non-integrating Sendai virus to generate multiple induced pluripotent stem cell (iPSC) lines from each 22qDS and control fibroblast line. We validated at least three iPSC clones per individual. To test the hypothesis that 22qDS schizophrenia patients have defects in layer III pyramidal neurons, we are currently deriving layer III pyramidal neurons from both the 22qDS and the control iPSC lines. We are developing platforms to validate the identity of the generated neurons at a single cell level to determine their expression profile, and to evaluate their capacity to form functional synapses.
Our system will enable the cellular and molecular analysis of a neuronal cell type highly associated with schizophrenia, and sets the stage for the development of analogous frameworks for the derivation and examination of additional neuronal subtypes associated with schizophrenia and other psychiatric disorders.

W-3245

DIRECT DERIVATION AND PROSPECTIVE ISOLATION OF SCHWANN CELL PRECURSORS FROM HUMAN PLURIPOTENT STEM CELLS

Bipasha Mukherjee-Clavin[1], Soojung Shin[2], Gabsang Lee[1]
[1]Institute for Cell Engineering, Johns Hopkins University School of Medicine, Baltimore, MD, United States, [2]Life Technologies Corporation, Frederick, MD, United States

Introduction: Genetic and acquired peripheral neuropathies are a significant source of disability, yet few effective treatments are available. Because of the role Schwann cells play in myelination and neuroregeneration, transplantation of Schwann cells or their precursor may offer a potential therapy in a subset of neuropathies. Here we report the derivation of Schwann cell precursors from human pluripotent stem cells. Method: A previously reported protocol for neuronal differentiation also yields Schwann cell precursors in close apposition to the neurons. Using dual-SMAD inhibition (with LDN-193189 and SB431542), followed by a cocktail of three small molecules (SU5402, CHIR99021 and DAPT) and subsequent treatment with ascorbic acid and cAMP, human embryonic (H9) and human induced pluripotent stem cells are effectively differentiated into putative Schwann cell precursors, using defined conditions. Results: Real time PCR demonstrates significant enrichment of PMP22, cadherin19, and myelin protein zero, and immunocytochemistry shows expression of S100B in the putative Schwann cell precursors. Additionally, we found that FACS for surface marker cd49d, an alpha4 integrin, allows for prospective isolation of this cell population following differentiation. Conclusion: Using a modified dual-SMAD inhibition protocol, we report the direct derivation and prospective isolation of Schwann cell precursors, in defined conditions.

SELECTIVE ABLATION OF THE TUMOR AFTER NSCS TRANSPLANTATION BY CONTROLLING THE IMMUNE SUPPRESSION.

Go Itakura[1], Yoshiomi Kobayashi[1], Yuichiro Takahashi[1], Satoshi Nori[1], Soraya Nishimura[1], Morito Takano[1], Tsunehiko Konomi[1], Hiroki Iwai[1], Akio Iwanami[1], Yoshiaki Toyama[1], Masaya Nakamura[1], Hideyuki Okano[2]
[A]Orthopedic surgery, [B]Physiology, [1]Keio university, Tokyo, Japan

Previously, we reported functional recovery after transplantation of mouse as well as human induced pluripotent stem cell-derived neurospheres (iPSC-NS) into rodents spinal cord injury (SCI) models (Tsuji et al, PNAS 2010; Nori et al, PNAS 2011). Although iPSCs are useful for SCI treatment, tumorigenicity of transplanted cells should be resolved before clinical applications. In this study, we sought to determine the feasibility of the selective ablation of the grafted cells by controlling the immune suppression.
We used human glioblastoma cell line (U251) and neurospheres derived from a human iPSC line (253G1), which is already evaluated as an unsafe clone in our previous study. First, we transplanted U251 cells into the intact spinal cord of NOD/SCID mice as well as C57BL6J mice with immune suppressors. In vivo bioluminescent imaging (BLI) was used to evaluate the survival of transplanted cells chronologically. The graft survival rate was 100 % (n = 9/9) in the NOD/SCID mice group, 0 % (n = 4/4) in the C57/BL6J mice group without immune suppressor and 100 % (n = 11/11) in the C57/BL6J mice group with immune suppressors. After confirming the growth of the grafted cells in the C57/BL6J mice with immune suppressors, immune suppression was discontinued. Then the grafted cells were rejected immediately. Through the histological evaluation, we confirmed the ablation of the grafted cells.
Next, we transplanted the 253G1-derived neurosphere into the spinal cord of BALB/Ca mice with immune suppressors. The graft survival rate was 100% (n = 17/17). The BLI-photon counts of the grafted cells increased gradually 6 weeks after transplantation, followed by the deterioration of motor function. After discontinuing the immune suppression, we observed the immediate rejection of the grafted cells and motor functional recovery in all the mice (n = 6/6). Through the histological analysis, we also confirmed the ablation of the graft derived tumor.
Taking advantage of the immune rejection, controlling a graft survival could be a safety lock against iPSC-NS derived tumor in the cell therapy for SCI.

ELECTRICALLY EXCITABLE SMALL NETWORKS OF NEURONS IN A HUMAN IPS 3-D SFEB SYSTEM.

Michael W. Nestor, Daniel Paull, Samson Jacob, Andrew A. Sproul, Abdulaziz Alsaffar, Brian A. Campos, Scott A. Noggle
The New York Stem Cell Foundation, New York, NY, United States

Three-dimensional aggregation cultures allow for complex development of differentiated human induced pluripotent stem cells. However, this approach is not easily amenable to live cell imaging and electrophysiological applications due to the thickness and the geometry of the tissue. Here, we present an improvement on the traditional aggregation method by combining the use of cell culture inserts with serum-free embryoid bodies (SFEBs). The use of this technique allows the structures to maintain their three-dimensional structure while thinning substantially. We demonstrate that this technique can be used for electrophysiological recording as well as live-cell calcium imaging combined with electrical stimulation, akin to organotypic slice preparations. This provides an important experimental tool that can be used to bridge 3-D structures with traditional monolayer approaches used in stem cell applications.

W-3248

SINGLE CELL CHARACTERIZATION OF MOTOR NEURONS DERIVED FROM HUMAN FIBROBLASTS AND PLURIPOTENT STEM CELLS

Sulagna Ghosh[1], Kevin Eggan[2], Steven McCarroll[1]
[1]Stanley Center for Psychiatric Research, The Broad Institute, Cambridge, MA, United States, [2]Dept. of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States

The recent advent of cellular reprogramming and iPS technology provides a powerful new means for modeling human diseases in a systematic, high-throughput and patient-specific manner. Despite the promise, effective modeling of complex neurological disorders has been hampered by our limited understanding of the inherent variability and heterogeneity of neuronal populations derived from pluripotent stem cells and patient fibroblasts. A method is needed to more rigorously classify in vitro derived neurons into discrete subtypes, both to diagnose the source

of cellular heterogeneity and to guide the development of standardized protocols for generating disease relevant cell subtypes. This study in particular aims to use single cell expression assays to better characterize the diversity and distribution of motor neuron subtypes in cultures generated via lineage specific reprogramming and transdifferentiation protocols. We anticipate that the results from this study will not only help model cell to cell variation in motor neuron cultures but also inform aspects of disease modeling that have previously been limited by cellular heterogeneity.

DERIVATION AND ISOLATION OF NKX2.1-POSITIVE BASAL FOREBRAIN PROGENITORS FROM HUMAN EMBRYONIC STEM CELLS

Noelle D. Germain[1], Erin Banda[2], Michaela Tolman[2], Janice Naegele[2], **Laura B. Grabel**[2]
[1]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, United States, [2]Biology, Wesleyan University, Middletown, CT, United States

Human embryonic stem cell (hESC)-derived ventral forebrain progenitors are ideal candidates for cell-based therapies that aim to replace dysfunctional or damaged cortical or hippocampal GABAergic interneurons. GABA-expressing interneurons are the major inhibitory cells of the cerebral cortex and hippocampus. These interneurons originate in the medial (MGE) and lateral (LGE) ganglionic eminences of the ventral forebrain during embryonic development and show reduced survival and function in a variety of neurological disorders, including temporal lobe epilepsy (TLE). While human ESCs (hESCs) are readily differentiated *in vitro* into dorsal telencephalic neural progenitors, standard protocols for generating ventral subtypes of telencephalic progenitors are less effective. We now report efficient derivation of MGE-like GABAergic progenitors using a modified monolayer neural differentiation protocol and an established hESC reporter line in which green fluorescent protein (GFP) is driven by the endogenous Nkx2.1 promoter. Consistent with sonic hedgehog (SHH)-dependent specification of NKX2.1-positive progenitors in the embryonic MGE, we show a dose-dependent increase in the generation of NKX2.1:GFP-positive progenitors following SHH treatment *in vitro*. Characterization of NKX2.1:GFP-positive cells confirms their identity as MGE-like neural progenitors, based on gene expression profiles and their ability to differentiate into GABAergic interneurons. We are also able to generate highly enriched populations of NKX2.1:GFP-positive progenitors by fluorescence activated cell sorting (FACS), and transplantation studies are underway to test the ability of these cells to differentiate and restore inhibitory activity in the mouse hippocampus.

OPTIMAL TIME POINT OF NEURAL STEM CELL TRANSPLANTATION THERAPY IS AT THE SUB-ACUTE PHASE OF SCI IN NON HUMAN PRIMATE

Soraya Nishimura[1], Kenji Yoshida[6], Hiroki Iwai[1], Yoshiomi Kobayashi[1], Shinsuke Shibata[2], Hayao Ebise[6], Ikuko Koya[2], Takashi Sasaki[3], Atsushi Shimizu[4], Jun Kudoh[5], Yoshiaki Toyama[1], Masaya Nakamura[1], Hideyuki Okano[2]
[A]Dept of Orthopaedics surgery, [B]Dept of Physiology, [C]Center for Integrated Medical Research, [D]Dept of Molecular Biology, [E]Laboratory of Gene Medicine, [1]Keio Univ. Sch Med, Tokyo, Japan, [2]Genomic Science Laboratories, Dainippon Sumitomo Pharma Co., Ltd.,, Osaka, Japan

INTRODUCTION: The microenvironment of injured spinal cord significantly affects the survival, the differentiation phenotype and the distribution of neural stem cells (NSCs) transplanted into the spinal cord. Analyses of microenvironmental changes of injured spinal cord, which are critical to determine a therapeutic time-window of NSCs transplantation for spinal cord injury (SCI), was previously reported in rodent SCI models, but not in a non-human primate SCI model. Here, we examined the global gene expression analyses to investigate microenvironment of injured spinal cord in adult common marmosets (Callithrix jacchus) to determine an optimal time-window of NSCs transplantation therapy in a primate SCI model.

METHODS: Contusive SCI was induced at C5 level in adult female common marmosets using a modified NYU impactor as reported previously. The injured spinal cord samples were harvested from each experimental animal at 1, 2, 4 and 6 WPI. Transcriptome analyses, such as microarray and next generation sequencing, were performed using these samples. The control animals received only laminectomy without SCI. Histological analyses including immunostaining for GFAP, Iba-1 and chondroitin sulfate proteoglycans (CSPG) of injured spinal cord were also performed at 1, 2 and 6 WPI.
RESULTS: Transcriptome analyses revealed that the expressions of genes associated with inflammatory cytokines, reactive oxygen and T cell activation were significantly up-regulated at 1 WPI and decreased at 2 WPI and thereafter. In contrast, the expressions of genes about synaptic transmission and neurotransmitter secretion were down-regulated at 1 WPI and elevated at 2 WPI and thereafter. Next, we focused on each indivisual gene expression. The expression of transforming growth factor (TGF) β, which was known as anti-inflammatory cytokine was drastically increased at 1 WPI and then decreased at 2 WPI followed by a gradual decrease until 6 WPI. In contrast, the expressions of most pro-inflammatory cytokines were already declined at 1 WPI. The markers of macrophages such as CD14 and CD68 were dramatically up-regulated at 1 WPI and then decreased rapidly to the control level at 2 WPI, whereas the expression of CSPGs was increased at 2 WPI and thereafter. Histological analysis revealed that more macrophages or microglial cells infiltrated around the lesion epicenter at 1 WPI than at the other time-points. Immunohistology for GFAP and CSPG showed that the glial scar formation and the CSPG accumulation were more prominent at 6 WPI compared with that at 1 and 2 WPI.
CONCLUSIONS: Taken together, the acute inflammatory response after SCI was diminished at 2 WPI, however the glial scar formation and the CSPG accumulation were already irreversible at 6 WPI. These findings suggested that the optimal time-window of NSCs transplantation might be around 2 to 4 WPI at the sub-acute phase of SCI in non-human primates.

W-3253

IMPROVEMENT OF MOTOR AND SENSORY FUNCTIONS IN A RODENT MODEL OF CONTUSED SPINAL CORD INJURY FOLLOWING TRANSPLANTATION OF BDNF-OVEREXPRESSING HUMAN NEURAL STEM CELLS (F3.BDNF)

Da-Jeong Chang[1], Hwi-Young Cho[2], Dong Ah Shin[3], Seyoung Hwang[1], Nayeon Lee[1], Iksoo Jeon[1], Chunggab Choi[1], Seung-Hun Oh[1], Hyun Sook Kim[1], Hyunseung Lee[4], Kwan Soo Hong[4], Young Wook Yoon[2], **Jihwan Song**[1]
[1]CHA Stem Cell Institute, Department of Biomedical Science, CHA University, Seoul, Korea, Republic of, [2]Department of Physiology and Neuroscience Research Institute, Korea University College of Medicine, Seoul, Korea, Republic of, [3]Department of Neurosurgery, Yonsei University College of Medicine, Seoul, Korea, Republic of, [4]Division of Magnetic Resonance, Korea Basic Science Institute, Ochang, Korea, Republic of

Spinal cord injury (SCI) represents the major form of paralysis and disabilities, but its therapeutic option is currently very limited or none. Numerous efforts have been made to cure SCI using stem cells, which gave rise to some promising results in animal experiments. However, since the halt of human embryonic stem cell-based clinical trial by Geron, further efforts to develop more efficient stem cell-based transplantation strategies in SCI became less active or minimized. In this study, we evaluated the therapeutic potential of human neural stem cells overexpressing BDNF (F3.BDNF) in a rodent model of contused spinal cord injury. BDNF (brain-derived neurotrophic factor) is known to play important roles in neuronal survival, neuroprotection, axonal regeneration, etc. F3.BDNF cells ($1x10^6$ cells in 10 μl) were delivered to the injury site intrathecally at 7 days after contusion injury at T11 level, and the transplantation effects were monitored up to 10 weeks using animal MRI and behavioral analyses. 4.7T MRI analysis indicated that Feridex-labeled F3.BDNF cells were mainly populated in the injury site, of which size was shown to be significantly reduced, compared with the sham control group. Histological analysis further revealed that the volume of lesion cavity was significantly reduced, whereas the extent of myelination was greatly increased in the F3.BDNF cell-transplanted group. Importantly, the transplanted animals exhibited improved behavioral recovery, judged by BBB and CBS tests. We also observed that transplanted F3.BDNF cells gave rise to significant sensory recovery, according to von Frey pain test. Immunocytochemical staining indicated that the transplanted cells were differentiated into both neural and glial lineages. Retrograde labeling using Fluoro-Gold demonstrated that the transplanted cells

were engrafted into the host tissue. We also found that the transplanted animals exhibited reduced numbers of Iba1, iNOS and GFAP-positive cells, suggesting that they can also modulate inflammation and gliosis after SCI. Taken together, these results indicate that human neural stem cells overexpressing BDNF can contribute to the functional improvement in a rodent model of SCI significantly, providing a new therapeutic possibility to treat SCI patients in the future.
This study was supported by a grant of the Korea Healthcare technology R&D project, Ministry for Health, Welfare & Family Affairs (A111016). We are grateful to the MRI facility in the Division of Magnetic Resonance, Korea Basic Science Institute, Ochang, Korea.

DEFINITIVE NEURAL STEM CELLS CLONALLY GENERATED FROM PLURIPOTENT STEM CELLS PROMOTE RECOVERY FOLLOWING SPINAL CORD INJURY

Ryan Salewski, Robert A. Mitchel, Michael G. Fehlings
Institute of Medical Science, University of Toronto, Toronto, ON, Canada

Despite advances in medical and surgical care, current clinical therapies for spinal cord injury (SCI) have limited effectiveness. Axonal demyelination is a key pathogenic mechanism following SCI that leads to an interruption of signal transmission and contributes to axonal degeneration. Cell-based therapies using neural stem cells (NSC) animal models of SCI have shown positive outcomes. Pluripotent cell sources such as embryonic stem cell (ESC) and induced pluripotent stem cell (IPSC) provide a limitless supply of therapeutic cells, the later allowing for patient-specific treatments. NSCs derived using embryoid bodies (EB) from ESC/IPSC in transplant and have been shown tumorigenic potential. The default pathway of neutralization may be used as an alternative method to generate safer and more clinically relevant NSCs without an EB intermediate for use in SCI cell-based therapy.
Using the default pathway we generate clonally derived definitive NSC (dNSCs) from ESC and IPSC sources. These cells are transplanted in a mouse thoracic spinal cord injury model. dNSC-transplanted mice were compared to control mice using behavioral measures (BMS, gait analysis) and histopathological analysis of tissue as well as the role of remyelination in injury recovery was investigated using transmission electron microscopy.
The SCI group that received dNSC transplantation showed significant improved in locomoter function compared to control injury in BMS evaluation. The gait analysis showed improved swing speed, stride length and coordinated stepping compared to controls. Furthermore the cell treatment group had a greater total area of spinal cord, grey matter and a trend towards increased white matter. Immunohistological assessments 8 weeks post injury showed that dNSCs differentiated to primarily to OLIG-2 positive oligodendrocytes. These cells were shown to expressed myelin basic protein, associated with axon and displayed proper compact, multilayer myelination.
This study suggests that dNSCs clonally derived from pluripotent cell using the default pathway of neuralization improves motor function following SCI, while remaining safe and clinically relevant.

A MICRORNA PROFILE OF REDUCED MIR-34B/C AND INCREASED MIR-592 IN ADULT EPILEPTIC PATIENT-DERIVED BRAIN CELLS REVEALS POTENT DISEASE BIOMARKER AND SCREENING TOOL FOR TRANSPLANTABLE STEM CELLS

Naoki Tajiri[1], Hiroto Ishikawa[1], Kazutaka Shinozuka[1], Travis Dailey[1], Yuji Kaneko[1], Teresita J. Malapira[1], Carmelina Gemma[2], Fernando Vale[1], Cesar V. Borlongan[1]
[1]Neurosurgery & Brain Repair, Univ of South Florida Morsani College of Medicine, Tampa, FL, United States, [2]Anesthesiology & Pain Medicine, Univ of Washington, Seattle, WA, United States

Over three million Americans suffer from some form of epilepsy, with mesial temporal lobe epilepsy (TLE) being the most common, arising from the temporal lobe structures of amygdala, hippocampus and parahippocampal gyrus. While many antiepileptic drugs are available, temporal lobectomy is the definitive treatment for intractable TLE. The present study sought to further understand the pathophysiology of epilepsy in an effort to develop more ef-

fective treatments for this disorder. Under USF IRB approval, tissues from multiple brain regions were obtained from consenting TLE patients undergoing hippocampal resection. Specimens were processed for microRNA and RT-qPCR analysis, while alternate tissues were grown in culture for immunohistochemical assays. Approximately 800 microRNAs were examined. Results revealed that miR-34b and miR-34c were significantly upregulated in hippocampus and amygdala compared to the neocortex, with miR-34b/c expression highest in the amygdala. In contrast, levels of miR-592 were significantly downregulated in the hippocampus and amygdala compared to the neocortex. Sister brain tissues of profiled microRNA samples were then processed for RT-qPCR focusing on the identified novel microRNAs. RT-qPCR data generally support microRNA data. Notably levels of miR-34b/c were significantly upregulated, while levels of miR-592 were downregulated in the hippocampus and amygdala compared to neocortex. In tandem, immunocytochemical staining against stem cell markers and cell survival/death provided insights into the function of these miRs, in that distinct cell growth patterns were recognized from stem cells harvested from brain-specific regions with cell proliferation and differentiation reduced in the hippocampus and amygdala compared to the neocortex of TLE patients. Intra-amygdalar transplants of stem cells derived from the neocortex (i.e., reduced miR-34b/c but elevated miR-592 expression) of epileptic patients not only survived in the amygdala and migrated to the hippocampal lesions, but also reduced hippocampal cell loss in rats subjected to kainic acid-induced epilepsy. Parallel in vitro studies revealed that the administration of the supernatant from cultured human epileptic neocortical stem cells significantly reduced the kainic acid-induced cell death in primary human hippocampal cells compared to control treatments, suggesting that the rescue of the epileptic hippocampus by the transplanted stem cells likely involves a trophic factor mechanism. This study elucidates the key role of microRNAs in the disease pathology of epilepsy and their utility as a stem cell optimization tool for identifying efficacious stem cells for transplantation therapy. A better understanding of the role of microRNAs in the disease pathology of TLE may lead to novel (i.e., stem cell-based) biomarkers and treatments for epilepsy and relevant disorders.

LIFEMAP^{TM} DISCOVERY- THE STEM CELLS, EMBRYONIC DEVELOPMENT AND REGENERATIVE MEDICINE RESEARCH PORTAL

Ronit Shtrichman, Ron Edgar, Yaron Mazor, Idit Livnat, Ariel Rinon, Shani Ben Ari, Ella Buzhor, **Jacob Blumenthal**, Netta Shraga, Yoel Bogoch,, David Warshawsky
LifeMap Sciences Ltd., Tel Aviv, Israel

Understanding how cells differentiate during embryonic development is invaluable for the derivation of functional cells from stem cells *in vitro*. The LifeMap Discovery database has been created to bridge these two research areas, and bring knowledge from the *in vivo* into the *in vitro*. Knowing the genes expressed in developing cells and the signaling that derives their differentiation is essential information for identification and classification of stem cells, and suggestive mechanisms to help develop differentiation protocols and therapeutic products.
LifeMap Discovery, available free of charge to all academics at http://discovery.lifemapsc.com, traces the cellular differentiation that occurs during mammalian development as well as information of stem cells differentiation. The database is based on systematic assimilation of scientific data describing developmental paths to their fates. The database includes cells and anatomy development, supplemented with qualitative gene expression, signaling pathways, *in situ* hybridizations and high throughout experimental data, related diseases, images and relevant references.
The database is divided into the following parts:
1.
In vivo development - Cell lineages developed in the mammalian body.
2.
Stem cell differentiation - cultured cells and differentiation protocols.

3.
Gene expression and Signaling - how and where genes are expressed, what signals contribute to differentiation.
4.
Regenerative Medicine - development of stem cells into therapeutic products.
These different parts are connected and interlaced by computational and hand curated methods, most noteworthy, the *in vivo* entities are linked to their closest *in vitro* entities, based on gene expression analysis.
The value provided by LifeMap Discovery originates from the combined power of this data, which enables identifying, predicting and indicating possible differentiation paths and future regenerative medicine applications. LifeMap Discovery integrates symbiotically with the more elemental database GeneCards where rich information is available at the gene level, and MalaCards, that provides human disease information.

T-1002

STEMBOOK, A RESOURCE FOR STEM CELL RESEARCHERS AND EXTENSIBLE PLATFORM FOR BIOMEDICAL WEB COMMUNITIES

Lisa Girard*[1], Sudeshna (Co-presenter) Das*[2], Stephane Corlosquet[3], Paolo Ciccarese[2], Timothy W. Clark*[2], Brock (co-senior author) Reeve*[1]

[1]Harvard Stem Cell Institute, Cambridge, MA, United States, [2]MIND Informatics, Massachussetts General Hospital, Harvard Medical School, Boston, MA, United States, [3]MIND Informatics, Massachussetts General Hospital, Boston, MA, United States

StemBook (www.stembook.org), is an original, open-access, peer-reviewed “book” with chapters covering topics in stem cell biology, commentaries, protocols, journal clubs, news, and forums. Written by top researchers in the field worldwide and geared toward stem cell and non-specialist researchers, but also appropriate within an undergraduate and graduate developmental biology curriculum, StemBook is divided into sections that span the basic to the translational. It represents a one-of-a-kind background resource with an online infrastructure equipped to continue evolving along with the field it covers. There are currently over 80 commissioned chapters and over 60 published chapters in StemBook. Each chapter represents a citable reference and is indexed in PubMed by the National Library of Medicine and appears on the NCBI Bookshelf. Since StemBook’s launch in September 2008, readership continues to grow dramatically and averages approximately 10,00 unique visitors each month.
The Scientific Collaboration Framework (SCF), co-developed by the MIND Informatics team at Massachusetts General Hospital, and the Harvard Stem Cell Institute, is a reusable platform for advanced structured digital collaboration. The first instance of this framework was used to create StemBook and several other web communities are now participating in the SCF ecosystem. SCF makes heterogeneous resources available to the collaborating scientist and captures the semantics of the relationship among the resources. The technology allows the wealth of StemBook content to be processed and mined.
Newly-enabled features include online journal clubs, news feeds and editor-moderated discussion forums. We are also creating user interfaces to support text mining and annotation of articles with stem cell vocabulary and resources. We are using a state of the art annotation tool, DOMEO (www.annotationframework.org) to markup StemBook articles. The proteins, biological processes, cell types/lines and hypotheses/claims within these articles are annotated with controlled vocabulary/ontology terms using the DOMEO tool. Such an annotation process provides an added service to the readers, whereby they can search for a term of interest and can retrieve the articles as well as the relevant context within the article. The application of newly-available technologies for semantics-based linking of biomedical web communities enables a new level of agile trans-disciplinary and translational collaboration in applications of

stem cell biology and regenerative medicine and will enable faster progress towards new clinical applications of stem cells.
Incorporating these features in the context of a top quality collection of original content geared directly at the stem cell research community creates a powerful means of reaching this reader base.
In collaboration with the NIH Center for Regenerative Medicine, StemBook has recently launched a methods and protocols section that provides readers with high quality, validated protocols for a wide range of stem cell research techniques and is overseen by StemBook but involves the coordination of over 10 major stem cell core facilities around the country. This section is transitioning to a forms-based approach with WYSIWYG capabilities with which users will be able to directly submit protocols, which will then be validated by the core facilities and potentially published as a vetted protocol.

T-1003

ETHICS OF TRANSLATIONAL STEM CELL RESEARCH: WHAT VALUE JUSTIFIES FIRST-IN-HUMAN TRIALS?

Annelien L. Bredenoord, Johannes JM Van Delden
Medical Ethics, University Medical Center Utrecht, Utrecht, Netherlands

Pluripotent stem cell (PSC) research has great potential for regenerative medicine, but is at the same time accompanied by a fierce ethical and political debate. This debate, however, has almost exclusively focused on the contested moral status of the human embryo. There is however a set of ethical issues relevant to both human embryonic stem cell and induced pluripotent stem cell research that are not related to the moral status of the embryo: the ethical issues associated with moving PSCs from bench to bedside. The first PSC trials have been initiated and more are under way. In this paper we will examine the ethical specifics of early-phase PSC trials.
First-in-human trials are ethically challenging by nature, particularly because the needed evidence to reliably predict risk and benefit (testing in humans) is missing. Whereas many innovative interventions raise ethical issues, PSCs trials are a new cutting edge where many ingredients come together including the unique risks and characteristics of PSCs, the inherent uncertainty of first-in-human studies, the sensitivity of the preclinical research, the relative unreliability of animal models, the potential vulnerability of research participants, the tremendous scientific and commercial stakes and the high public and political attention. In the initial applications of a first-in-human PSC trial it is likely that the risks and uncertainties are higher than the direct-benefits for the research participants. As such a trial cannot be deemed therapeutic, the question becomes whether early-phase PSC trials can be justified otherwise when potential risks and uncertainties outweigh direct-benefits to research participants. A possible answer to this ethical dilemma is that such trials could still be morally acceptable when the *value* of the study is sufficient to justify the risks, i.e. there are sufficient potential benefits to science and society (instead of direct-benefits to participants). This, however, raises some further questions that are relatively unaddressed yet.
The concept of value is brought to bear in all influential codes of research ethics but is scantly discussed and elucidated. What exactly entails value in clinical research, and what kind of value is a trial expected to generate? If this is for example knowledge, then one could wonder how compatible this is with the Declaration of Helsinki that states that “the well-being of the individual research subject must take precedence over all other interests” (article 6). A strict interpretation of the Declaration of Helsinki may therefore imply that many if not most first-in-human studies are unjustifiable.
If the ethical permissibility of first-in-human PSC trials can be justified with an appeal to value, then this sets several additional criteria, for example regarding outcome measures, scientific design, value maximization, risk minimization, knowledge utilization, participant selection and informed consent.

CURRENT JAPANESE GUIDELINES ON ENSURING QUALITY AND SAFETY OF PRODUCTS DERIVED FROM PROCESSING OF HUMAN STEM CELLS

Takao Hayakawa[1], Takashi Aoi[2], Akihiro Umezawa[3], Keiya Ozawa[4], Yoji Sato[5], Yoshiki Sawa[6], Akifumi Matsuyama[7], Shinya Yamanaka[2], Masayuki Yamato[8]

[1]Pharmaceutical Research and Technology Institute, Kinki University, Osaka, Japan, [2]Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan, [3]Department of Reproductive Biology, National Research Institute for Child Health and Development, Tokyo, Japan, [4]Division of Hematology, Department of Medicine, Jichi Medical University, Tochigi, Japan, [5]Division of Cellular and Gene Therapy Products, National Institute of Health Sciences, Tokyo, Japan, [6]Department of Surgery, Osaka University Graduate School of Medicine, Osaka, Japan, [7]Division of Regenerative Medicine Development Assistance, Foundation for Biomedical Research and Innovation, Hyogo, Japan, [8]Advanced Biomedical Science Center, Tokyo Women's Medical University, Tokyo, Japan

Regenerative medicine using relevant products
derived from various human stem cells are being keenly anticipated in Japan due to limited resources of human organs and tissues transplantation and difficulty of treatments to cure various severe diseases. The more advances in stem cell science, the more people expect the effective and efficient translation into regenerative medicine. Identifying points to consider for ensuring quality, safety and efficacy of products derived from the various types of stem cells is crucial through product development for their rapid application in patients. Technical requirements for manufacturing and marketing authorization of cells/tissue-based products under the Japanese Pharmaceutical Affairs Law, are described in the Notification No. 1314 of Secretary-General of Pharmaceutical and Food Safety Bureau (PFSB), Ministry of Health, Labour and Welfare (MHLW), dated December 26, 2000. The 2006/2007 Scientific Research Group of the MHLW looked into preparing a revised version of "Guideline on Ensuring Quality and Safety of Products Derived from Processing of Human Cells/Tissue", which is Appendix 2 in the PFSB/MHLW 1314, in response to requests that Japan should push forward with appropriate regulations for regenerative medicine through the revision of assessment criteria that reflects rapidly developing science and technology, ethical viewpoints, and international trends. This revision, splitting the original guideline up into 2 different guidelines in order to make clearer the specific technical requirements for products derived from autologous cells and allogenic cells, led to the publication of the "Guideline on Ensuring Quality and Safety of Products Derived from Processing of Human Autologous Cells/Tissue" (PFSB/MHLW Notification 0208003) in February 2008, and the "Guideline on Ensuring Quality and Safety of Products Derived from Processing of Human Allogenic Cells/Tissue" (PFSB/MHLW Notification 0912006) in September 2008, respectively. However, further studies became necessary to identify specific issues related to products derived from processing of somatic stem cells, embryonic stem cells or induced pluripotent stem cells (iPSCs), all of which have been attracting a lot of attention in recent years. At this point, the MHLW decided to form in fiscal year 2008. a panel of experts (the authors of this presentation) for drafting guidelines on ensuring the quality and safety of products derived from processing of various human stem cells. At the presentation, we address the current guidelines concerning the basic technical requirements for ensuring the quality and safety of products derived from processing of human stem cells, which the MHLW released on September 7, 2012. The guidelines reflect the results of the study on the current situation

and future outlook, from a scientific and technological perspective, of the manufacture and clinical application of human stem cell-based products.

T-1005

REGULATION OF CELL AND TISSUE THERAPY - A WAY FORWARD FOR UNPROVEN INTERVENTIONS

Peter ONeill, Chih W. Teng
Management, Monash University, Melbourne, Australia

On 23th of July 2012, a district court in Washington DC ruled in favour of FDA seeking an injunction against Regenerative Sciences Inc., a company providing autologous stem cell therapy for orthopaedic injuries. The ruling of the court has given legitimacy to the FDA's push to regulate autologous therapies in the US. This may mean that autologous therapies, which are classified as excluded goods, will have to conform to the same review process as drugs, and be regulated in much the same way. This occurs against the background of the increasing number of private stem cell clinics and stem cell tourism, which largely go unregulated. This phenomenon occurs not only in the US, but also in countries such as the UK and Australia. Whether the decision by the district court works towards the progress of the field is spilt between two views.

Members of the scientific and bioethics community who favour the decision have cited the following prominent arguments. Firstly, robust methods must be applied to all therapies to ensure clinical results can be validated through a certified test/trial regime. Secondly, clear governance structures need to be in place to protect the patient from misleading claims.

The counterpoint adopted by professional and practitioner groups argues that the FDA has encroached into the practice of medicine. By adopting a legalistic approach the FDA has breached the sacrosanct line that separates the regulation of medical practice from the regulation of medical products. Furthermore, commercial entities and some patient advocacy groups contended that translation and commercialization of autologous cell therapies would be delayed if the current lengthy drug review process were instigated.

We thus contend that:

1. Funding providers such as insurance agencies and medicare heavily influence the rate of an innovations adoption into routine practice. Such entities provide financial assistance via subsidies and reimbursements that help offset the costs to patients. Without regulator approval or endorsement by relevant authorities, it is expected that the rate of adoption will slow tremendously.
2. Practitioner led commercialisation is heavily influenced by the ability to leverage on technology platforms that help deliver positive patient outcomes. Without access to enabling technologies that help deliver therapies closer to points of care, it is expected that the rate of adoption will decline.

Thus in terms of maximising the greatest good from these investments, it is paramount that attempts are made to reconcile conflict between rate of the commercialisation process and the rate of adoption.

Using Diffusion Theory as a theoretical lens for our case study, we collected information through interviews with key representatives of the international regenerative medicine industry.

Our findings suggest that to satisfy ISSCR Guidelines for the Clinical Translation of Stem Cells (2008:15-16) Recommendation 34, and the Australian TGA Excluded Goods Order Number 1 2011, a regulatory framework should encompass the following:

1.
The licencing of clinician-scientists (at practice level) to perform (excluded/autologous) stem-cell procedures
2.
The establishment of a controlled register of procedures that can be performed
3.
All patient data must be maintained on their personal-e-health record (and accessible by researchers)
4.
Limitations to the extraction of cell types at practice level
5.
Limitations of cellular manipulation ex vivo at practice level

LIFELINES: STEM CELL RESEARCH IN A GLOBALIZED WORLD

Brooke M. Ellison
School of Health Technology and Management, Stony Brook University, Stony Brook, NY, United States

Matters of science traditionally have been looked at from two sociological perspectives. The Sociology of Scientific Knowledge (SSK) argues that science is similar to other socially constructed phenomena, and is a product of context. From this perspective, science and culture have an inextricable relationship. World Polity Theory (WPT), on the other hand, makes the argument that science is a rationalistic entity that exists outside of cultural forces. However, as science becomes increasingly complex and multidimensional, these two theories leave room for additional analysis. Bourdieu's Field Theory brings to light how interactions between social actors make certain social realities possible, and create the environments for the development of policy matters. This theoretical approach is a necessary addition to better understand science as it is codified in policy. The scientific field of embryonic stem cell research is an ideal site to apply these theoretical frameworks.
Stem cell research is a matter of biology that incorporates complex epistemic questions like the status of life, respect for human dignity, and the value of science as a source of economic production. As a result, the policy surrounding human embryonic stem cell research takes on social contestation not directed to other areas of scientific investigation even within the biomedical sector. The globalized nature of stem cell research is seen in organizations like the International Society for Stem Cell Research (ISSCR). The culturally-determined nature of stem cell research is seen in the diversity of local concerns that it highlights: concerns that incorporate ethical, epistemic, and economic questions. Both of these competing ideas come into play as policymaking entities and powerful social actors negotiate ways to address the stem cell question.
This analysis investigates stem cell research legislation in four contexts: the US, UK, Germany, and China. Each of these cases presents a set of considerations, which changes the landscape of the political field in which stem cell research has evolved. In these cases, the impact of four social actors has been addressed: the Catholic Church, scientific community, pharmaceutical industry, and patient advocacy community. How these actors operate in each context is dependent on a confluence of social forces. The US' stem cell policymaking has been defined by a battle for epistemic authority on issues of life. The UK case illustrates the role of expertise as authority in democratic policymaking. The German case illustrates the ways in which collective memory of iconic events operates through social actors. And, China represents a control case, indicating how policy can evolve in circumstances where the political field is limited. Taken together, these cases illustrate how Sociology of Scientific Knowledge, World Polity Theory, and Field Theory can work together to explain complex modern science.
This analysis demonstrates the need for a more synthetic approach among analytical frameworks. In the US and Germany, there is a stem cell policy that has been characterized by some degree of ethical concern. Alternatively, in the UK and China, there is a stem cell policy that has been characterized by a degree of liberality. The result is four cases, two with a restrictive stem cell policy and two with a progressive stem cell policy, yet each with a set of dynamics that shapes the social field and influence how social actors operate within it.

T-1007

EMERGING PRIVACY CHALLENGES IN CELL THERAPY RESEARCH: THE CANADIAN CONTEXT

Sarah Burningham
Faculty of Law, University of Alberta, Edmonton, AB, Canada

Innovations in cell therapy research have the potential to revolutionize health care. However, the need for robust privacy protection of genetic information is particularly important in the context of cell therapy research, given policies, introduced to address pragmatic and logistical concerns associated with consent and withdrawal of consent, which have limited the rights of individuals to control and withdraw their tissue from research. For example,

most biobanks now use broad consent models and some policies and regulations limit the right of individuals to withdraw consent to tissue research to a time before a cell line is created.
Cell therapy research presents unique challenges for privacy regulation. While cell therapy research generally involves funding and research collaboration by multiple private and public actors, privacy regulation is traditionally divided on public-private lines, making application of privacy statutes to a given project challenging. Additionally, several recent studies have demonstrated that de-identified genetic information can be re-identified by combining this information with other identifying information available in publicly-accessible databases, challenging the notion that de-identification is a sufficient guarantee of privacy in this context. However, privacy legislation in Canada does not apply to de-identified information, meaning it falls outside the scope of legislative protection.
My objective is to provide an overview of privacy regulation of cell therapy research in Canada. I will identify challenges associated with privacy regulation and highlight gaps in the current legislative and judicial frameworks that apply to this research. In particular, I will argue that reform is needed to address the risks of re-identification respecting de-identified genetic information, as such information is currently excluded from the scope of privacy regulation.

A COLLABORATIVE ROLE FOR PATIENT ADVOCATES IN DEVELOPING REGULATORY SCIENCE FOR GOVERNMENT APPROVAL OF STEM CELL-BASED AND REGENERATIVE MEDICINES

Alan L. Jakimo[1], Bernard Siegel[2]
[1]Sidley Austin LLP, New York, NY, United States, [2]Genetics Policy Institute, Wellington, FL, United States

Stem cell science and regenerative medicine have benefited during the past decade from the efforts of patient advocates. Continuation of these efforts from patient advocates will be a key to the success of the increasing number of stem cell-based and regenerative medicines that undergo clinical translation and reach the stage of consideration by government regulators charged with approving market authorization applications submitted by the sponsors of these medicines. This raises the question as to whether patient advocates are sufficiently schooled in the language and dynamics of the regulatory approval process so that they can make a meaningful and thoughtful contribution to that process. At the same time, as a general matter, government regulators responsible for approving medical products are focusing their efforts on improving existing regulatory science tools and developing new ones. (FDA defines regulatory science as “the science needed to assess and evaluate a product’s safety, effectiveness, quality, and performance” and suggests that it “can be a critical link between cutting-edge discoveries and real-world diagnostics, treatments, and cures.”) Here we propose that patient advocates can play an important role in the development of regulatory science for medical products arising from SCS&RM.
First, we review how patient advocates have historically participated in the regulatory approval process, particularly with respect to medical products related to SCS&RM. Second, we review current efforts by government regulators, such as FDA, to improve regulatory science in general. Third, we suggest specific elements of regulatory science that need to be improved or freshly developed for SCS&RM-related medical products. Fourth, we hypothesize how patient advocates can participate in this process of improving and developing regulatory science for SCS&RM-related medical products.
We test our hypothesis by reference to a specific instance of the regulatory approval process for an SCS&RM-related medical product and the ongoing efforts of FDA in the field of regulatory science. We observe here the importance of collaboration between and among patient advocates and other stakeholders.
We conclude by suggesting a series of symposia in venues around the globe for training patient advocates in the intersection of regulatory science and the government approval process as it relates to SCS&RM medical products and in building relevant collaborations with other stakeholders. These symposia will require the participation of scientists and physicians.

INDUCED TUMOR GENERATING CELLS (ITGC) FOR A WIDE EVOLUTIONARY RANGE OF SPECIES

Ricardo A. Rossello[1], Ute Hochgeschwender[2], Rui Dai[2], Erich D. Jarvis[3]

[1]Biochemistry, University of Puerto Rico Medical Sciences Campus / University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, United States, [2]Neurobiology, Duke University, Durham, NC, United States, [3]Neurobiology, Duke University / Howard Hughes Medical Institute, Durham, NC, United States

Cells are fundamental units of life, but little is known about evolution of cell states. Induced pluripotent stem cells (iPSCs) are once differentiated cells that have been re-programmed to an embryonic stem cell (ESC) state, providing a powerful platform for biology and medicine. Previously, our group published findings that showed iPSC-like cells can be induced in vertebrate and invertebrate model organisms that span 550 million years from a common ancestor: in mammals, birds, fish, and fly. Parallel to this effort we noticed a large number of transformed colonies that were being formed. These cells were not stem cells, but, in some cases, had transformed characteristics. Here, we examine these cells for mouse, chicken, and quail, and noticed they had a variety of features. First, some of the cells expressed a high level of telomerase activity while others had none. These cells were separated into two distinct subsets. The first group had significantly high level of proliferative capacity, while the second group did not. Secondly, they all expressed OCT-4, TERT, SSEA1, KLF-5, and ERAS.
Because they expressed pluripotent markers, additional to Oct-4, Sox-2, KLF-4, and C-myc, a pluripotent state seemed to be present. Surprisingly the slow proliferating group contained a larger set of pluripotent markers than did the fast, self renewing cells. These cells were injected into mice testes to assess teratoma formation. However, in both cases, the tumor that ensued was unstructured, suggesting carcinogenicity. In addition, to reject the possibility of these cells being induced stem cells, we injected them into embryos. In all cases (n=10, per species), embryogenesis was halted.
To further characterize these cells _____

Targeting Cancer Stem Cells by “Signal-Smart” Oncolytic Viruses

Kaoru Terai Terai, Zhengian Liu, Emma Borrego-Diaz, Ayten Gadashova, Judith L. Larson, Tuba Esfandyari, **Faris Farassati**

Medicine, The University of Kansas-School of Medicine, Kansas, KS, United States

Cancer stem cells (CSCs) comprise a novel concept in molecular oncology. According to this concept, in resemblance to normal tissues, tumors contain a fraction of cells in charge of maintaining the functional and structural integrity of the tumor while generating different types of cells forming the malignant mass. These cells are referred to as CSCs and have been shown to be highly resistant to conventional chemo and radiotherapy. Although different studies have proven the validity of the concept of CSCs, the translational correlation between this concept and cancer therapy remains to be explored. In other words, if targeting cancer stem cells can result in a robust tumor regression remains as an attractive topic for investigation. In this regards, we have developed a novel version of oncolytic herpes viruses with the capability to target CSCs on cell-specific basis.
Oncolytic viruses are a promising class of replication competent viruses that in many cases, such as herpes model, have passed phase I clinical trials. These viruses replicate conditionally in the cancer cells leading to their destruction. Oncolytic virus therapy is based on the ability of viruses to effectively infect and kill tumor cells with minimal or no effects on normal tissues. While some viruses seem to have a natural preference for tumor cells, most viruses require the modification of their tropism to specifically enter and/or replicate in cancer cells. To this end, we have developed the first mutated version of herpes simplex virus-1(HSV-1) which is capable of replication in CSCs in a specific manner. CD133 is one of the most important markers for cancer stem cells involved in the biology of a number of human cancers. The virus developed in this work, referred to as Signal-Smart 2 or SS2 virus, shows specificity against CD133+ cells in three different models (liver cancer, colorectal cancer and melanoma) resulting in the loss of viability and invasiveness of these cells and eventual demise of the whole tumor cell population. The SS2 virus also showed a robust inhibitory activity against the growth of related tumor cells *in-vivo*. Additionally,

pre-established tumors regressed significantly once treated with this virus. The results of this study, not only introduce SS2 as a novel agent for targeting CSCs, but also establish CSCs in general (and CD133+ cells in specific) as a relevant target for future development of anti-cancer therapeutics. On the other hand, the concept of CSCs, as the main driving force behind the integrity of the tumor is further established by our studies.

HETEROGENEITY OF SINGLE CELL GENE EXPRESSION ACROSS PHENOTYPICALLY DISTINCT POPULATIONS OF SINGLE CELLS AS MEASURED BY RNASEQ.
J.F. Shuga, A. Leyrat, N. Li, B. Fowler, P. Chen, X. Wang, J. Wang, S. Weaver, M. Unger1 & J. A. West1,
1New Technologies, Fluidigm Corporation, South San Francisco, CA
Multi-cellular populations are fundamentally driven by the collective properties of individual cells. However, our understanding of gene expression dynamics derived from cultures or tissues are based on measurements made from the entire population. A growing body of data collected from individual cells has challenged these basic assumptions. The data suggest that properties driving lineage, development and disease emerge from the transcriptional heterogeneity and signaling architectures of distinct sub-populations of cells. To understand this heterogeneity more fully we have performed mRNA transcriptome analysis of single cells across a wide sampling of phenotypically distinct populations. Using a automated system the capture, imaging, and routine preparation of full-length mRNA-sequencing libraries of single cells we have enabled the delineation of transcriptional heterogeneity within and between cell populations at the level of the individual cell. We present data that compares full length amplified transcriptome profiling by both high throughput gene expression using the BioMark HD system as well as downstream NGS sequencing of prepared cDNA libraries.

THE IDENTIFICATION OF BRAIN METASTASIS INITIATING CELLS AND REGULATORS OF BRAIN METASTASIS FROM LUNG CANCER

Chitra Venugopal[1], Sara Nolte[1], Mohini Singh[1], Branavan Manoranjan[1], Nicole McFarlane[1], Olena Morozova[2], Robin Hallet[1], Erin O'Farrell[1], Naresh Murty[1], Edward Kachur[1], John Provias[1], John Hassell[1], Marco Marra[3], Sheila Singh[1]
[1]McMaster University, Hamilton, ON, Canada, [2]BC Cancer Agency, Vancouver, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada

Brain metastases (BMs) are most common in adults suffering from lung cancer, predicting uniformly poor patient outcome, with a median survival of only months. Despite their frequency and severity, very little is known about the tumorigenesis of BMs. We hypothesize that BMs contain a subpopulation of cells with stem cell properties, termed brain metastasis initiating cells (BMICs), that is responsible for the initiation of the brain metastasis. We applied our previously developed primary brain tumor-initiating cell (BTIC) models to the study of BMs from the lung to determine the presence of a stem-like population in BMs. Use of both patient samples and NCI-H1915, a lung to brain adenocarcinoma cell line, enabled us to determine useful strategies for study of BM.
We observed that brain metastases possess BMICs, and they have comparable sphere-forming capacity and stem cell frequency to primary brain tumor controls, are able initiate tumor growth, reproduce original tumor heterogeneity through in vivo differentiation, and can be serially passaged in vivo. We developed a BMIC xenotransplantation model, and injected BMICs into NOD-SCID mice via three routes (intracranial, intrathoracic to lung, and intravas-

cular) to assess for subsequent development, frequency and lethality of brain metastases. The minimally-cultured BMIC xenografts accurately recapitulated the patient tumor, and BMIC lines may also provide a suitable supply of cells when assessing the effects of new therapeutics on self-renewal or tumor growth.
We aimed to identify novel genes and/or pathways specifically overexpressed in brain metastasis tumorspheres. Transcriptome analysis obtained by RNA seq data was used to compare genes between brain metastasis tumorspheres, primary lung and primary brain tumors to determine genes overexpressed exclusively in the brain metastasis stem cell population. We identified 30 overexpressed genes that may have roles in lung-to-brain metastasis, including genes involved in cell adhesion, cytoskeleton rearrangements, proliferation/tumorigenesis, and formation/disruption of cell-cell junctions. To confirm their relevance to brain metastasis, we tested the predictive power of the candidate genes for overall patient survival, as poor survival of lung cancer patients strongly correlates with brain metastasis. We examined patient survival in a larger homogenous dataset of 226 primary lung tumors (GSE31210). Of the selected 28 candidate genes, 11 were associated with length of patient survival.
For the first time, we demonstrate the presence of a stem-like population in brain metastases from the lung. Our new model system provides a much needed method to study brain metastases from the lung, and is unique in its application of the CSC model to in vitro and in vivo assay development. Future studies will focus on elucidating the functional role of the selected genes overexpressed in the BMIC population. Our candidate genes may be essential to metastatic stem cell populations, where pathway interference may be able to transform a uniformly fatal disease into a more localized and treatable one.

T-1015

MIR-18B REGULATES SELF-RENEWAL OF GLIOBLASTOMA CANCER STEM-LIKE CELLS THROUGH NOTCH2, NEDD9, AND MEKK1

Xing Fan, Xiaobing He, Jason Heth, Karin Muraszko
Neurosurgery, University of Michigan, Ann Arbor, MI, United States

Glioblastoma (GBM) is the most common malignant brain tumor in human with extremely poor prognosis and new treatment for this deadly disease is desperately needed. Cancer Stem-like cells (CSCs) have been prospectively isolated from GBM and shown required for tumor propagation. We and others have demonstrated recently that differentiation of GBM neurospheres decreases GBM cell propagation both in vitro and in vivo (Zhu et al, Cancer Research, 71:6061-72, 2011). In the current study, we found that miR-18b was up-regulated upon differentiation of GBM neurosphere. When we introduced miR-18b into GBM neurospheres by lentivirus, we found that miR-18b decreases clonogenesis and growth of three different GBM neurosphere lines, indicating that GBM CSC population was reduced by miR-18b. Mechanistically, we found that miR-18b down-regulates luciferase activity of 3'-UTR reporters of NOTCH2, NEDD9, and MEKK1. Furthermore, protein expression of NOTCH2, NEDD9, and MEKK1 are also decreased by miR-18b, suggesting that NOTCH2, NEDD9 and MEKK1 are the direct targets of miR-18b in GBM CSCs. In addition, we have demonstrated previously that NOTCH regulates GBM CSC propagation through pAKT (Fan et al, Stem Cells, 28:5-16, 2010). Here, we found that pAKT and pERK1/2 were also down-regulated in miR-10b infected GBM neurosphere lines, indicating that miR-18b reduces GBM CSC propagation through NOTCH2/pAKT pathways. Taken together, we have demonstrated that miR-18b functions as a tumor suppressor and decreases GBM CSC propagation through targeting NOTCH2, NEDD9, and MEKK1, indicating that miR-18b can be a potential therapeutic molecule to target GBM CSCs and improve GBM treatment.

T-1016

INVOLVEMENT OF mTOR SIGNALING PATHWAYS IN REGULATION AND MAINTENANCE OF CANCER STEM CELLS OF GLIOBLASTOMA MULTIFORME

Dhruve S. Jeevan, Marissa D. Friedman, Michael Prendergast, Michael Tobias, Raj Murali, Meena Jhanwar-Uniyal
Neurosurgery, New York Medical College, Valhalla, NY, United States

Glioblastoma Multiforme (GBM) is a uniformly fatal primary brain tumor that renders poor prognosis despite current treatment modalities. Recurrence of tumor is attributed to the presence of treatment resistant cancer stem cells (CSCs) within the tumor. The hypothesis that tumors originate from CSCs has been strengthened by the findings that CSCs expressing specific markers isolated from the tumor mass of GBM are capable of generating tumors of the same genotype and phenotype within *in vivo* models. Treatment strategies' involving targeting of these CSCs is therefore crucial in the treatment of this disease.

One of the genes that appear to be responsible for tumor growth and progression is tumor suppressor gene PTEN, which acts via a canonical pathway of lipid kinase PI3K/AKT. Downstream of oncogene AKT is mechanistic target of Rapamycin (mTOR), which forms two multiprotein complexes, namely mTORC1 and mTORC2 that regulate cellular proliferation, growth, as well as migration. Recent studies have provided evidence that these complexes are also involved in CSC regulation. Moreover, the role of MAPK in differentiation of stem cells has been suggested. Here we delineate the role of mTOR/MAPK pathways in CSC maintenance and self-renewal, and further establish the means of targeting CSCs.

Our study demonstrates that a significant number of GBM tumors expressed activated $mTOR^{Ser2448}$ as well as stem cell marker Nestin. In culture, neurospheres derived from GBM cells expressed the markers of pluripotency (Musashi, Nanog, Nestin), the ability to differentiate into neurons (β-III-tubulin) and astrocytes (glial fibrillary astrocytic protein), and self-renewal capability. Genetic inhibition of mTORC components with the use of siRNA (Rictor, Raptor, or p70S6K) alters stem cell characteristics by influencing differentiation as well as maintenance of pluripotency. The differentiating agent all-trans retinoic acid (ATRA) was able to cause differentiation of neurospheres and reduce the levels of Nestin. mTOR or MAPK inhibitors influenced this effect. Proliferation of neurospheres, as measured by neurosphere diameter was suppressed by ATRA, Rapamycin (mTORC1 inhibitor) or U0126 (MAPK inhibitor) treatments. Further, self-renewal of CSCs was altered by mTOR/MAPK inhibition. While ATRA decreased neurosphere diameter by inducing differentiation, the inhibitors of mTOR and MAPK did so by suppressing the activation of down-stream target S6Kinase.

CSC differentiation and maintenance of pluripotency have clinical implications since these properties relate directly to the aggressive nature of GBM. Evidence that inhibitors of mTOR can influence CSC regulation suggests its potential therapeutic use.

T-1017

ESTABLISHMENT OF OSTEOSARCOMA CELL LINES ASSOCIATED WITH OSTEOID FORMATION AND LUNG METASTASIS BY USING PLURIPOTENCY-RELATED SMALL MOLECULES

Masaki Kawamata, Takahiro Ochiya
National Cancer Ctr Res Inst, Tokyo, Japan

It has been generally considered that establishing cancer cell lines while remaining their pathological characteristics is difficult because of a lack of effective culture methods. We have recently established rat embryonic stem cell (ESC) lines by adding 4 inhibitors YPAC that block ROCK, MEK, TGF beta and GSK3 signaling. YPAC could inhibit differentiation of the rat ESCs, leading to infinite proliferation while maintaining a state of inner cell mass of blastocysts. Here we use the YPAC medium to establish new cancer cell lines from an osteosarcoma that was spontaneously caused in a p53 heterozygous male rat. In this rat, lung metastasis was caused and osteoid formation was observed both in primary and the metastasized tumors.

YPAC medium allowed cancer cells of the primary tumor to adhere actively on collagen-coated dish, followed by continuous proliferation by passaging with enzymatic dissociation. However, cells could not proliferate under basic cell culture condition composed of 10% FBS in DMEM without YPAC (-i) nor 3i culture condition that have been generally used for rat ESC culture. In the osteosarcoma cell line cultured with YPAC (OSC+YPAC line), large population of cells kept alkaline phosphatase (ALP) activity of osteoblast marker after a long-term culture. Withdrawal of YPAC from the culture medium (OSC+YPAC to -i) induced cellular senescence and these cells lost ALP activity. To assess tumorigenicity, 3x106 cells of the OSC+YPAC or OSC+YPAC to -i cell line were transplanted subcutaneously to SCID mice. In 12 weeks, the OSC+YPAC cell line developed subcutaneous tumor with osteoid formation and such osteoid were metastasized to the lung. In contrast, OSC+YPAC to -i cell line did not show tumorigenicity. Here we succeeded

in establishing osteosarcoma cell line associated with lung metastasis and osteoid formation, which entirely reflect the pathological state of tumor spontaneously caused in a p53 mutant rat. We have demonstrated that YPAC is effective not only for establishing cancer cell lines but also for maintaining pathologic characteristics of tumors.

T-1018

XIAP INHIBITORS INDUCE DIFFERENTIATION AND IMPAIR CLONOGENIC CAPACITY OF ACUTE MYELOID LEUKEMIA STEM CELLS

Daniel Moreno-Martínez[1], Meritxell Nomdedeu[1], Marta Pratcorona[2], Marina Díaz-Beyá[2], Maria Rozman[3], Jordi Esteve[2], **Ruth M. Risueño**[1]

[1]Institut De Recerca Contra La Leucèmia Josep Carreras, Barcelona, Spain, [2]Department of Hematology, Hospital Clínic de Barcelona-University of Barcelona, Barcelona, Spain, [3]Department of Hematopathology, Hospital Clínic de Barcelona, Barcelona, Spain

Acute myeloid leukemia (AML) is a neoplasia characterized by the rapid expansion of immature myeloid blasts in the bone marrow. The course of the disease is marked by poor prognosis, frequent relapse, and high disease-related mortality. As such, new therapeutic approaches are required for remission induction and prevention of relapse. Due to the higher chemotherapy sensitivity and limited life span of more differentiated AML blasts, differentiation-based therapies combined with cytotoxic agents are a promising therapeutic approach. Based on public available gene expression profiles, a myeloid-specific differentiation-associated gene expression pattern was defined as the therapeutic target. An in silico screening was performed to identify small compounds that induce similar changes in the gene expression profile and a XIAP inhibitor (Dequalinium chloride, DQA) was validated. DQA, similarly to Embelin (another XIAP inhibitor), showed cytotoxicity against AML cells. Myeloid differentiation, downregulation of key signaling-mediator molecules and cell cycle arrest were observed after DQA treatment. Moreover, XIAP inhibition differentially impaired cell viability of the most primitive AML blasts and reduced clonogenic capacity of AML cells. Taken together, these results suggest that XIAP constitute a potential target for AML treatment and support the evaluation of XIAP inhibitors in clinical trials.

T-1021

IN VITRO COPMARISION OF A NOVEL HYALURONIC ACID-BASED DRUG DELIVERY SYSTEM AND FOLATE-RECEPTOR-TARGETED DELIVERY OF DOCETAXEL NANOPARTICLES AS TARGETED DRUG DELIVERY TO PROSTATE CANCER STEM CELLS

Reyhaneh Khoshchehreh[1], Navid Goudarzi[2], Mahdi Khoshchehreh[3], Rasoul Dinarvand[2], Marzieh Ebrahimi[1]

[1]1Department of Stem Cells and Developmental Biology, Royan Institute for Stem Cell Biology and Technology, Tehran, Iran, Islamic Republic of, [2]Faculty of Pharmacy, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of, [3]Keck School of Medicine, University of Southern California, Los Angeles, CA, United States

Cancer stem cells (CSCs) possess high tumor-initiating capacity and have been reported to be resistant to therapeutics. It has been assumed that drug-resistant cancer cells may all be CSCs although the generality of this assumption is unknown. The engineering of drug-encapsulated targeted nanoparticles (NPs) has the potential to revolutionize targeted drug therapy in cancer. Here, we synthesized two different biofunctional polymers composed of HA:Cisplatin and PLGA-PEG-Folate. The physicochemical properties of the obtained nanoparticles were characterized by: dynamic
light-scattering analysis for their mean size, size distribution, and zeta
potential; and differential scanning calorimetry analysis for confirmation of molecular dispersity of cisplatin and docetaxel in the nanoparticles.
Nanoparticles were spherical with an average size of 200 nm in diameter and positive zeta potential values. For in vitro evaluation, prostate cancer cell lines were treated with these NPs, which led to populations of drug tolerant cells (DTCs). Surprisingly, these DTCs, when treated with docitaxel NPs, exhibited much reduced tumorigenicity

whereas HA-Cis treated cancer cells demonstrated no reduction in tumorregenerating capacity. DTX-NPs-treated cancer cells demonstrated low proliferative and clonogenic potential. Interestingly, DTX-NPTs-tolerant cancer cells showed decreases in many ‘‘stemness’’genes. Our results thus revealed that FOL-targeted NPs showed a high cytotoxicity effect in the prostate cell lines and showed a greater extent of intracellular uptake in FOL-receptor-positive cancer cells in comparison with the HA-Cis NPs.

T-1022

ACTIVATION OF CANONICAL WNT/BETA-CATENIN PATHWAY SUPPRESSES EMBRYONAL RHABDOMYOSARCOMA GROWTH AND SELF-RENEWAL BY DECREASING TUMOR PROPAGATING CELL NUMBER.

Eleanor Chen, Michael DeRan, Myron Ignatius, Ryan Clagg, Xu Wu, David Langenau
Massachusetts General Hospital, Charlestown, MA, United States

Embryonal rhabdomyosarcoma (ERMS) is a common soft tissue malignancy of childhood and phenotypically recapitulates fetal or regenerating muscle arrested at early stages of differentiation. The prognosis for patients with relapsed disease remains poor with 50% of patients succumbing to their disease. Thus, there is a clinical imperative to identify novel drugs that target relapse-associated cells. Work from our group has recently identified the tumor-propagating cell (TPC) in zebrafish ERMS that is responsible for driving relapse. The TPC is molecularly similar to a muscle satellite cell that expresses myf5, c-met, and m-cadherin. Targeting these cells for destruction would likely provide new therapies for the treatment of advanced RMS. Toward this end, we have successfully performed two independent chemical genetic screens using 47% of the FDA approved compounds and an additional 37,800 investigational compounds to identify drugs that suppress zebrafish ERMS growth in vivo by modulating the frequency of the TPCs and that elicit differentiation of human ERMS cells in vitro. From these large-throughput screens, GSK3-beta inhibitors, including BIO and lithium-chloride emerged as the most promising hits. GSK3-beta inhibitors lead to stabilization of beta-catenin and activation of canonical Wnt pathway. The role of canonical Wnt pathway in ERMS tumor progression remains poorly understood. In our study, BIO treatment of tumor-bearing zebrafish resulted in suppressed tumor growth by depleting myf5-GFP+ TPCs and in turn inducing differentiation of myf5-GFP+ TPCs into mature myosin expressing ERMS cells. More importantly, the myosin-positive ERMS cells lack self-renewing capacity as demonstrated by limiting dilution cell transplantation experiments. Specifically, treatment of BIO resulted in a 20-fold reduction in frequency of TPCs. We have now extended our findings to six clinically available GSK3-beta inhibitors, all of which have shown efficacy in suppressing human ERMS proliferation and in causing differentiation in vitro. A subset of these drugs is being assessed for efficacy in inhibiting growth of human ERMS in xenograft mouse models. In total, our work has identified the therapeutic potential of using GSK3-beta inhibitors for the treatment of relapsed RMS.

T-1023

CHARACTERIZATION OF TCF-DEPENDENT AND INDEPENDENT FUNCTIONS OF β-CATENIN IN COLORECTAL CANCER

Matthew G. Murphy[1], Maria Sol Flaherty[3], Ramanuj Dasgupta[2]
[A]Stem Cell Biology, [B]Cancer Institute, [1]NYU School of Medicine, New York, NY, United States, [2]City University of New York, NYCCT, New York, NY, United States

Misregulation of the Wnt/β-catenin signaling pathway is required for colorectal cancer (CRC), as mutations in the pathway are found in a vast majority of CRC patients. These mutations lead to an accumulation of β-catenin, which can translocate to the nucleus, where it interacts with transcription factors including the TCF/LEF family. Targets of β-catenin/TCF transcription include CyclinD1 and c-Myc, which function in cell growth and proliferation. The Wnt pathway has an important function in stem cells, as it has been implicated in both embryonic stem cells (ESCs) and cancer stem cells (CSCs). While much of the research on the Wnt pathway is focused on TCF-mediated transcription, β-catenin has been shown to interact with a number of other factors, including E-cadherin, which is critical for cell-cell adhesion, and pluripotency factors such as Oct4 and Klf4.

While β-catenin has been shown to be required in ESCs, evidence has shown that its interaction with TCF/LEF transcription factors is not. This lead us to investigate whether there is a similar requirement for β-catenin in CSCs which are responsible for tumor initiation. To investigate this, we used an *in vitro* sphere formation assay as a model for tumor initiation. We utilized a combination of TCF-transcriptional reporters, small molecule inhibitors, and inducible shRNA lines to assess the requirement of β-catenin/TCF transcription for maintenance of colorectal CSCs. We found that blocking the interaction between β-catenin and TCFs with small molecules developed by our lab reduces proliferation but does not prevent sphere formation or maintenance. In addition, we found a correlation between the expression of a TCF-transcriptional reporter and the ability of a single cell to form a sphere. Moving forward, we are translating our *in vitro* findings into an *in vivo* mouse model to determine the requirement for TCF transcription in tumor initiation.

EVIDENCE SUPPORTING A CANCER STEMNESS HIERARCHY IN OVARIAN CANCER.

Brendan Ffrench[1], Louise Kehoe[2], Brendan Doyle[1], Aoife Cooke[1], Britta Stordal[1], Sharon O'Toole[1], Cara Martin[1], Orla Sheils[1], John O'Leary[1], Michael Gallagher[1]

[1]Histopathology and Morbid Anatomy, Trinity College Dublin, Dublin, Ireland, [2]Histopathology, Coombe Women's Hospital, Dublin, Ireland

Mouse tumorigenicity studies identify cancer stem cells (CSCs) as the
founding cells of tumors. Therapeutically targeting CSCs could remove the tumors malignant potential and circumvent chemoresistance, relapse and metastasis. The presence of multiple tumorigenic populations in tumors complicates CSC directed therapies. However, if multiple tumorigenic populations are part of a single stemness hierarchy it may be possible for a single therapeutic approach to target the entire hierarchy.
Six models of ovarian malignancy and one model of normal ovarian surface epithelium were screened for the presence of OvCSCs and somatic stem cells respectively. Three flow cytometry based CSC screens were implemented; ALDEFLUOR^{TM} (ALDH), Hoechst Side-Population and Cell Surface Protein (CD44, CD117, CD133, CXCR4) assays. Cells of interest were isolated via fluorescence-activated cell sorting (FACS). Putative CSCs (pCSCs) were validated in NOD.SCID mouse tumorigenicity assays (malignant potential) and single cell asymmetric division (AD) assays (differentiation and self-renewal potential).
The CSC screen identified pCSC populations ranging in size from 0.06 %
CD133+ (A2780 cell line) to 99.51 % CD44+ (59M cell line). All CSC screening assays identified pCSCs in one or more of the models screened. All models investigated contained pCSC populations marked by one or more assay. Multiple pCSC populations were identified within most cell lines. The sizes of these populations indicate that the pCSC populations do not overlap perfectly suggesting the possibility of hierarchical sub-populations of CSCs.
The ALDH+ pCSC and ALDH- non-pCSC populations identified in the A2780 and A2780cis cell lines were isolated and brought forward for i*n*
vivo and *in vitro* validation. Mouse tumorigenicity studies showed that both ALDH+ and ALDH- cells could produce xenograft tumors from 500 cells with equal efficiency. The AD assay showed that the ALDH+ cells were capable of differentiation and self-renewal. It also showed that the ALDH- population consisted of two cell types: i) ALDH_NegA cells, which can differentiate and self-renew to produce ALDH+ and ALDH- cells and ii) ALDH_NegB cells, which can not differentiate and only produce ALDH- cells. Further mouse tumorigenicity studies demonstrated that
ALDH_NegB also have a reduced malignant potential.
These results indicate the presence of an ALDH_NegA -> ALDH+ ->
ALDH_NegB cancer stemness hierarchy. It suggests that both ALDH_NegA and ALDH+ populations are tumorigenic. It is therapeutically advantageous to identify such hierarchies as it means that targeting a stemness hierarchy may be sufficient to remove the malignant
potential from the tumor as opposed to individually targeting multiple CSC populations.

Currently no ALDH_NegA/NegB markers have been identified. These populations can only be distinguished functionally. Microarray analysis is pending to identify such markers. Microarray analysis is also pending on 'undifferentiated' OvCSC populations and their differentiated counterparts to identify molecular targets to force differentiate these cells and to establish stable OvCSC models.

T-1025

THE REPRESSION OF NEGATIVE REGULATORS OF STEMNESS PATHWAYS IN LUNG CANCER

Erh-Hsuan Lin[1], Ting-Yu Kuo[1], Teh-Ying Chou[2], Yu-Chung Wu[3], Cheng-Wen Wu[1]
[1]Institute of Biochemistry and Molecular Biology, National Yang Ming University, Taipei, Taiwan, [2]Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, [3]Division of Thoracic Surgery, Department of Surgery, Taipei Veterans General Hospital and School of Medicine, Taipei, Taiwan

Stemness genes and pathways play important roles in embryonic development and adult tissue regeneration. Recent years, the aberrant activations of stemness signaling such as Hedgehog (HH), hypoxia-inducible factor (HIF), and Wnt pathways, and the stemness factors like Oct-4 and Sox-2 have been reported in lung cancers. However, most researches to date focused on the impact of positive regulators of stemness pathways in oncogenesis, but less on the importance of negative regulators. Here, using a mutant EGFR-mediated oncogenic transformation model in human lung epithelial cells, we found that Hedgehog interaction protein (HHIP) and HIF-3α, which are negative regulators of HH and HIF pathways, respectively, were significantly repressed in transformed cells. This observation was confirmed in several lung cancer cell lines and in human lung tumor samples. The repression of these genes was due to epigenetic silencing on their promoters. The overexpression of HHIP or HIF-3α significantly inhibited the colony formation, migration, and invasion abilities of lung cancer cells in response to stemness pathway activations. These results implicate the importance of EGFR-induced epigenetic alternations, and suggest that in lung cancer oncogenesis, the negative regulators of stemness pathways can be silenced and thus potentiate lung cancer cells to activate stemness signaling to acquire the abilities of survival, metastasis, and drug-resistance in adverse environments.

SOX4 IS A MASTER REGULATOR OF EPITHELIAL-MESENCHYMAL TRANSITION (EMT) BY CONTROLLING EZH2 EXPRESSION AND EPIGENETIC REPROGRAMMING

Neha Tiwari[1], Vijay Tiwari[2], Lorenz Waldmeier[3], Piotr Balwierz[3], Phil Arnold[3], Mikhail Pachkov[3], Nathalie Meyer Schaller[3], Dirk Schübeler[4], Erik van Nimwegen[3], Gerhard Christofori[3]
[1]University Medical Center Mainz, Mainz, Germany, [2]Institute for Molecular Biology gGmbH (IMB), Mainz, Germany, [3]University of Basel, Basel, Switzerland, [4]Friedrich Miescher Institute for Biomedical research, Basel, Switzerland

Employing computational analysis of gene expression kinetics, we uncovered the transcription factor Sox4 with up-regulated activity during TGFβ-induced EMT in normal and cancerous breast epithelial cells. Sox4 is indispensable for TGFβ-induced EMT and cell survival in vitro and for primary tumor growth and metastasis in vivo. In addition to a number of EMT-relevant genes, Sox4 directly regulates the expression of Ezh2, encoding the Polycomb group histone methyltransferase that is known to trimethylate histone 3 lysine 27 (H3K27me3) for gene repression. Knockdown of Ezh2 expression prevents EMT, while forced expression of Ezh2 restores EMT in Sox4-deficient cells. Moreover, genome-wide analysis of H3K27me3 levels at consecutive stages of EMT revealed significant dynamics of H3K27me3 at the promoters of key EMT genes, and corresponding changes in their expression. Importantly, the epigenetic EMT signature predicts breast cancer patient survival. Our results provide a novel mechanism of EMT control by the transcription factor Sox4 which by governing the expression of critical EMT genes, as well as components of epigenetic machinery acts as a master regulator of EMT.

T-1027

KARYOTYPICALLY ABNORMAL HUMAN EMBRYONIC STEM CELLS ARE SENSITIVE TO HDAC INHIBITORS AND SHOW ALTERED REGULATION OF GENES LINKED TO CANCERS AND NEUROLOGICAL DISEASES

Lund Riikka J[1], **Maheswara Reddy Emani**[1], Barbaric Ivana[2], Kivinen Virpi[3], Jones Mark[2], Baker Duncan[2], Gokhale Paul[2], Harrison Neil[2], Nykter Matti[3], Lahesmaa Riitta[1], Andrews Peter W[2]
[1]University of Turku and Åbo Akademi University,, Turku Centre for biotechnology, Turku, Finland, [2]Department of Biomedical Science, The University of Sheffield, Centre for Stem Cell Biology,, Sheffield, United Kingdom, [3]Tampere University of Technology, Department of Signal Processing, Tampere, Finland

Genomic abnormalities may accumulate in human embryonic stem cells (hESC) during in vitro maintenance. Characterization of the mechanisms enabling survival and expansion of abnormal hESCs is important due to consequences of genetic changes for the therapeutic utilization of stem cells. Furthermore, these cells provide an excellent model to study transformation in vitro. We report here that the histone deacetylase proteins, HDAC1 and HDAC2, are increased in karyotypically abnormal hESCs when compared to their normal counterparts. Importantly, similarly to many cancer cell lines, we found that HDAC

inhibitors repress proliferation of the karyotypically abnormal hESCs, whereas normal cells are more resistant to the treatment. The decreased proliferation correlates with downregulation of HDAC1 protein, induction of the proliferation inhibitor, cyclin-dependent kinase inhibitor 1A (CDKN1A), and altered regulation of tumor suppressor protein Retinoblastoma 1 (RB1). Through genome-wide transcriptome analysis we have identified genes with altered expression and responsiveness to HDAC inhibition in abnormal cells. Most of these genes link to severe developmental and neurological diseases and cancers. These genes include factors linked to severe developmental disorders and neuronal disorders, such as Alzheimer's disease. Furthermore, most of these genes are linked to cancers, in particularly to those common in childhood. Our results highlight the importance of epigenetic mechanisms in the regulation of genomic stability of hESCs, and provide valuable candidates for targeted and selective growth inhibition of karyotypically abnormal cells.

HOX GENES ARE UPREGULATED IN MALIGNANT COLONIC STEM CELLS AND ARE KEY TO THEIR SELF-RENEWAL

Seema Bhatlekar[1], Bruce Boman[1], Vignesh Viswanathan[1], Shirin Modarai[1], Lynn Opdenaker[1], Nicholas Petrelli[1], Jeremy Fields[2]

[1]Center for Translational Cancer Research, Helen F. Graham Cancer Center, University of Delaware, Newark, DE, United States, [2]CA TX Inc., Gladwyne, PA, United States*

Stem cells (SCs) regulating self-renewal pathways are critical for normal functioning of the colon whereas alteration of these pathways through cancer stem cells (CSCs) is key to colon tumorigenesis. The mechanisms of such alterations are not clear. HOX genes play a role in regulating stem cells (SCs) during embryologic development. Because HOX genes are aberrantly expressed in many cancers, we investigated the possibility that HOX genes are key to self-renewal of normal and malignant colonic stem cells. We hypothesized that (1) specific HOX genes are aberrantly expressed in CSCs in malignant colon and (2) this aberration is necessary for self-renewal of colon CSCs. PCR-based array analysis showed that most HOX genes are upregulated in colon carcinomas relative to normal colonic epithelium. Array results were validated using real-time PCR, western blots and immunohistochemistry. We discovered that HOXA4, HOXA9 and HOXD10 are expressed at the base of normal crypts, where most normal colonic SCs reside. Immunocytochemical analysis of SW480 and HT29 colon cancer cells showed up-regulation of HOXA4, HOXA9 and HOXD10. Using flow cytometry and Aldefluor assays, we isolated SCs and non-SCs from colon cancer cell lines and showed that HOXA4 and HOXA9 gene expression is increased in CSCs relative to non-CSCs. In normal SCs, HOXA4 and HOXA9 were co-expressed with SC markers ALDH1A1 and CD166. Colon carcinoma tissues also showed this co-staining and the number of co-stained cells was substantially increased relative to normal colonic epithelium. We studied functional roles of HOX genes in colon CSCs using treatment with retinoid agents and then sphere formation assays. Exposure of colon cancer cells to retinoid agonists induced down-regulation of HOXA4 and HOXA9 genes, decreased expression of the SC marker ALDH1A1, and reduced colonosphere formation. Taken together, our results indicate that over-expression of HOX genes is key to self-renewal of colon cancer CSCs, a mechanism that underlies growth of colon carcinomas. Strategies designed to target HOX genes may be a way to eradicate colon CSCs and may lead to the development of more effective therapies for colon cancer.

T-1031

CONVERSION OF HUMAN IMMORTALIZED CELLS TO CANCER STEM CELL-LIKE CELLS

Seung-ick Oh

Department of Biomedical Science, College of Health Science,, Korea University, Seoul, Korea, Republic of

Current models of stem cell and cancer biology assume that cancer stem cells (CSCs) reside at the apices of hierarchies, and are directly involved in the maintenance and progression of various types of cancer. Recently, it has been reported that a population of a primary tumor and oncogenes-expressing primary fibroblasts can reconstitute the original tumor on xenotransplantation. Here, we show that the human immortalized cell lines were converted

to CSC-like cells using our new *in vitro* culture system. We found that the CSC-like cells showed the expression of CD133, CD15, CD44, Nestin, NCAM, c-Myc and TERT, which have all been suggested to mark the CSC population. In our *in vitro* tumor-sphere formation experiments, the CSC-like cells efficiently formed tumor-spheres. In addition, our *in vivo* tumorigenecity experiments showed that only 10 cells of CSC-like cells were sufficient to initiate tumors in immunocompromised mice. These results showed the establishment of an experimental system to understand human CSC properties and suggested that pre-cancerous cells may have the potentials to be converted to CSCs.

A NOVEL PRO REPROGRAMING FACTOR GLIS1 IS REGULATED BY HYPOXIA INDUCIBLE FACTORS VIA NON CANONICAL MECHANISM

Elham Khalesi[1], Keiji Tanimoto[2], Hideaki Nakamura[3], Andika Chandra Putra[2], Takahiro Fukazawa[1], Takeshi Imura[1], Yumi Kawahara[1], Yuichi Makino[4], Lorenz Poellinger[3], Louis Yuge[1]
[1]Department of Bio-Environmental Adaptation Sciences, Graduate School of biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan, [2]Department of Radiation Medicine, Research Institute for Radiation Medicine, Hiroshima University, Hiroshima, Japan, [3]Department of Cell and Molecular Biology, Karolinska Institutet, stockholm, Sweden, [4]Department of Medicine, Asahikawa Medical University, Asahikawa, Hiroshima, Japan

GLI-similar 1 (*GLIS1*) is a member of Krüppel-like zinc finger transcription factors that are closely related to GLI family. During mouse embryonic development, *Glis1* was expressed in a temporal and spatial manner; expression was prominent in several defined structures of mosodermal lineage, including craniofacial region, branchial arches, somites, vibrissal and hair follicles, limb buds, and myotomes. In adult mice, *Glis1* expression was observed abundant in placenta and adult kidney, and low in testis, thymus, colon, brain, and adipose tissue. Furthermore, significant induction of *Glis1* expression was observed in psoriatic epidermis and in mouse skin with the tumor promoter phorbor-12-myristate-13-acetate (PMA) treatment. However, the molecular mechanisms of regulation of *Glis1* expression in both physiological and pathological conditions have been mostly undetermined.
Glis1 was interestingly demonstrated to enhance markedly the generation of induced pluripotent stem cells (iPSCs) from both mouse and human fibroblasts when it is expressed together with *OCT3/4* (*POU5F1*), *SOX2*, and *KLF4*. DNA microarray analyses revealed that *Glis1* effectively promoted the direct reprogramming of somatic cells during iPSCs generation through activation of multiple pro-reprogramming pathways. It was also demonstrated that iPSCs generation was enhanced under hypoxic conditions, although underlying molecular mechanisms was still unclear. We thus examined whether hypoxia regulates *GLIS1* expression, and tried to clarify the molecular mechanisms behind this.
At first, variety of cell lines - MCF-7, MDA-MB-231, BT-474, SKBR-3, ZR-75-1 breast cancer cells; HSC-2, HSC-3, HSC-4, Ca9-22, KOSC-2 oral cancer cells; A549 lung cancer cells; HepG2 liver cancer cells; RCC4/pcDNA, RCC4/VHL kidney cancer cells - were incubated under normoxic (21% pO_2) or hypoxic conditions (1% pO_2) for 24 hours. Real-time RT-PCR analyses demonstrated that *GLIS1* expressed relatively higher in MCF-7 and RCC4 among cell lines tested. Interestingly, *GLIS1* expressions were dramatically increased in hypoxic conditions in some cell lines as well as known hypoxia-inducible genes, *ADM* and *CA9* and pro-reprogramming genes, *POU5F1* and *KLF4*. Importantly, *GLIS1* expression was significantly lower in VHL-transfected RCC4 cells than that in control RCC4. Furthermore, knock-down experiments demonstrated that inhibition of Hypoxia-inducible factors (HIFs) abolished hypoxic induction of *GLIS1* expression. Time course experiments showed that expression of *GLIS1* was gradually increased until 48 hours in hypoxic MCF-7 cells not only at mRNA but also at protein levels. A series of promoter analyses demonstrated that *GLIS1* transcription was regulated by hypoxia through HIF-dependent mechanism. Co-transfection analyses revealed that HIF-2[[Unsupported Character - Symbol Font ]] had more potent capacity on *GLIS1* promoter activation. Further analyses using wild-type, mutant types of HIF-2[[Unsupported Character - Symbol Font ]] lacking bHLH or C-terminal transactivation domains, or IPAS, demonstrated that protein-pro-

tein interaction was important but DNA binding was not necessary. These results suggest that the VHL-HIF pathway may play a pivotal role in regulation of the pro-reprogramming factor gene, *GLIS1*, *via* non-canonical mechanisms.

CBFβ-SMMHC INACTIVATES P53 TUMOR SUPPRESSOR THROUGH ABERRANT PROTEIN INTERACTION AND RECRUITMENT OF HDAC8

Jing Qi[1], Sandeep Singh[1], Qi Cai[1], Ling Li[1], Hongjun Liu[1], Hieu Vu[1], Tinisha Mcdonald[1], Yinwei Ho[1], Chung-I Chang[2], ravi bhatia[1], Ya-Huei Kuo[1]

[1]hematopoietic stem cell & leukemia, City of Hope National Medical Center, Duarte, CA, United States, [2]Institute of Biochemical Sciences, National Taiwan University, Taipei, Taiwan

Chromosomal inversion inv(16)(p13.1q22) is found in approximately 12% of acute myeloid leukemia (AML) patients, and leads to the fusion of the transcription factor gene CBFb and the MYH11 gene, and encodes a fusion protein CBFβ-SMMHC. Expression of CBFβ-SMMHC predisposes for leukemia transformation, however, the molecular mechanism underlying the leukemogenic function of CBFβ-SMMHC remains elusive. The tumor suppressor p53 is considered the master genomic guardian that is frequently mutated in a wide variety of tumors but is rarely mutated in inv(16) AML. Thus, we examined whether CBFβ-SMMHC fusion protein might impair p53 function. We found that p53 acetylation (Ac-p53) level was reduced in the presence of CBFβ-SMMHC fusion protein in the myeloid progenitor 32D cell line as well as in primary pre-leukemic bone marrow progenitor cells isolated from the conditional Cbfb-MYH11 knock-in (Cbfb56M/+/Mx1-Cre) mice. We showed that expression of p53 target genes are reduced in the presence of CBFβ-SMMHC fusion protein, indicating the p53 transcriptional activity was impaired, which is consistent with the impaired Ac-p53. To understand the mechanism, we found that CBFβ-SMMHC fusion protein interacts with p53 both in 32D cells and primary bone marrow cells. It has been reported that CBFβ-SMMHC interacts with histone deacetylase 8 (HDAC8) through the C-terminal SMMHC region, and we were able to detect a multimeric protein complex containing CBFβ-SMMHC, p53, and Hdac8. We further showed that Hdac8 knock-down led to robust increase in Ac-p53 levels while total p53 levels were modestly stabilized. In addition, treatment with HDAC8 remarkably increased Ac-p53To access whether HDAC8 plays a role in the deacetylation of p53, we used two independent small-hairpin (sh)-RNA to knock-down Hdac8 in 32D-CBFβ-SMMHC cells. To test whether this effect is dependent on the deacetylase function of HDAC8, we used HDAC8 selective pharmacological inhibitors (HDAC8i including PCI-34051 and 22D) directed against its catalytic sites. in both control and CBFβ-SMMHC cells. Since p53 protein levels were also increased upon HDAC8i treatment, we included Mdm2 inhibitor Nutlin-3 to stabilize p53. HDAC8i treatment alone or in combination with Nutlin-3 was able to enhance Ac-p53 compared to Nutlin-3 treatment, confirming its effect in restoring p53 acetylation. In order to test the function of HDAC8 in human stem progenitor cells (HSPCs), we treated HSPCs purified from normal human sample or inv(16) patient samples with HDAC8 specific inhibitor for 2 days, and result shows that the HSPCs from inv(16) samples are more sensitive to HDAC8 inhibitor compared to the normal samples, and the inhibitor is showing a selective induction of apoptosis from 5uM to 40uM. Collectively, our study shows that the CBFβ-SMMHC fusion protein forms an aberrant complex with p53 and HDAC8, leading to the aberrant deacetylation and impaired activity of p53. In addition, this deacetylation of p53 conferred by CBFβ-SMMHC is mediated by HDAC8. Our study reveals a novel leukemogenic mechanism in which CBFβ-SMMHC disrupts p53 activation through aberrant protein-protein interaction and recruitment of HDAC8.

SEARCH FOR PATHOGENESIS OF ACQUIRED MYELODYSPLASTIC SYNDROMES USING REPROGRAMMING TECHNOLOGY

Kazuhisa Chonabayashi[1], Masahiro Kawahara[2], Akira Watanabe[1], Keisuke Okita[1], Masatoshi Nishizawa[1], Akifumi Takaori-Kondo[2], Shinya Yamanaka[1], Yoshinori Yoshida[1]

[1]*Department of Reprogramming Science, Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan,* [2]*Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal stem cell diseases characterized by inefficient hematopoiesis and risk of progression to acute myeloid leukemia with poor prognosis. Although the incidence of MDS is relatively high, these diseases remain poorly understood, mainly due to a difficulty in the ex vivo culture of primary MDS cells and a lack of good animal models. Induced pluripotent stem cells (iPSCs) could act as a new platform for elucidation of the pathogenesis of MDS.
We used episomal methods to generate iPSCs from peripheral blood mononuclear cells of a MDS patient (RAEB-1 by WHO classification) with isolated 20q deletion. We established more than 30 iPSC lines derived from primary MDS cells (MDS-iPSC lines) as well as 6 normal iPSC lines derived from T cells (T-iPSC lines) of the same patient in parallel from the peripheral blood samples. Karyotyping and SNP-CGH analysis revealed that all MDS-iPSC lines have the chromosomal deletion (20q11.2-13.1) identical to those of the primary MDS cells, whereas all T-iPSC lines have normal diploid. All MDS-iPSC lines display characteristic morphology and expressed pluripotent stem cell markers at levels comparable to those in T-iPSC lines and ES cell lines. Five out of 7 selected MDS-iPSC lines formed teratomas so far.
We assessed hematopoietic differentiation potential of 7 MDS-iPSC lines and 6 isogenic normal T-iPSC lines using the OP9 co-culture system and the embryoid body differentiation culture system. Differentiation into hematopoietic stem cells (HSCs) of MDS-iPSC lines was comparable to T-iPSC lines. However, hematopoietic colony formation in methylcellulose culture and further differentiation in erythroid and neutrophil culture were severely impaired in all tested MDS-iPSC lines. Microarray analysis showed that 422 genes were up-regulated (fold change >2) and 308 genes were down-regulated (fold change <0.5) in MDS-iPSC-derived HSCs compared to T-iPSC-derived HSCs. In MDS-iPSC-derived HSCs, 46 genes located on 20q11.2-13.1 had reduced expression by at least 2 fold (74 genes by 1.5 fold) compared to the HSCs derived from the normal diploid T-iPSC lines. This iPSC-based system could be useful for studying the precise molecular mechanisms of MDS and testing new therapeutic compounds.

Elite Model for the Generation of Induced Pluripotent Cancer Cells (iPCs)

Jason Lai[1], Chiou Mee Kong[1], Dashayini Mahalingam[1], Xiaojin Xie[1] & Xueying Wang[1].
[1]Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore.
[*Keywords:* iPCs; Stochastic Model; Elite Model; NSCLC; reprogramming]
Abstract
The inefficiency of generating induced pluripotent somatic cells (iPS) engendered two contending models, namely the Stochastic model and Elite model. Although the former is more favorable to explain the inherent inefficiencies, it may be fallible to extrapolate the same working model to reprogramming of cancer cells. Indeed, tumor cells are known to be inherently heterogeneous with respect to distinctive characteristics thus providing a suitable platform to test whether the reprogramming process of cancer cells is biased. Here, we report our observations that all randomly picked induced pluripotent cancer cells (iPCs) established previously do not possess mutations known in the parental population. This unanticipated observation is most parsimoniously explained by the Elite model, whereby putative early tumor progenies were selected during induction to pluripotency.

INVESTIGATING THE ROLE OF MYF5 IN EMBRYONAL RHABDOMYOSARCOMA

Ines M. Tenente, Myron S. Ignatius, Eleanor Y. Chen, David M. Langenau

Molecular Pathology/Center for Cancer Research, Massachusetts General Hospital, Charlestown, MA, United States

Embryonal rhabdomyosarcoma (ERMS) is an aggressive pediatric sarcoma of muscle. Our group has recently shown that ERMS tumor-propagating potential is confined to a molecularly-distinct cancer cell type that expresses myf5 and additional satellite cell markers. Importantly, tumor-propagating cells (TPCs) drive continued tumor growth and are thought to drive relapse. Using a zebrafish transgenic model of ERMS, we have recently identified the myf5:GFP+/mylz2:mCherry-negative subpopulation as the TPC in this disease. Importantly, MYF5 is significantly upregulated in a majority of zebrafish, mouse, and human ERMS. Given that MYF5 has important roles in normal and regenerating muscle development, is highly expressed in muscle satellite cells, and is sufficient to reprogram human primary mesenchymal cells into muscle; we questioned if it exerts important roles in ERMS. We hypothesized that myf5 and its transcriptional targets are responsible for eliciting stem cell self-renewal programs within a subset of ERMS cells. To assess if myf5 is sufficient to drive ERMS self-renewal, we forced its expression in differentiated myosin expressing cells that normally lack tumor propagating potential. We find that myf5 expression confers self-renewal to this ERMS cell subpopulation. To assess if myf5 is required for tumor initiation, we have also generated ERMS in myf5-deficient zebrafish. Our data suggests that myf5 is important for ERMS initiation, as time to tumor onse is delayed when compared with fish that have intact myf5 signaling. In total, our data suggest important roles for myf5 in regulating ERMS growth and self-renewal.

MICRORNA-30C REGULATES BREAST CANCER STEM CELLS AND EMT BY TARGETING TWF1 AND VIM

Huiping Liu[1], Jessica Bockhorn[1], Chika Nwachukwu[2], Simo Huang[1], Ya-Fang Chang[1], Aleix Prat[1], Dezheng Huo[2], Jun Lu[4], Charles Perou[5], Olufunmilayo I. Olopade[3], Geoffrey Greene[1], Michael Clarke[6]
[A]Ben May, [1]The University of Chicago, Chicago, IL, United States, [C]Medicine, [1]The University of Chicago, Chicago, IL, United States, [2]Yale University, New Haven, CT, United States, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [4]Stanford University, Stanford, CA, United States

Our previous studies demonstrated that breast cancer stem cells (BCSCs) are actively involved in spontaneous metastases of patient tumor-derived human-in-mouse orthotopic breast tumor models. BCSCs have also been reported to mediate resistance to conventional chemotherapy and radiotherapy. However, the molecular mechanisms underlying BCSCs, metastasis and chemo-resistance are poorly characterized. We hypothesized that microRNAs link epithelial-to-mesenchymal transition (EMT) to BCSC-mediated metastasis and therapy resistance. Our work discovered that miR-30c, a human breast tumor prognostic marker, plays a pivotal role in linking metastasis and chemo-resistance by a direct targeting of cytoskeleton genes TWF1 and VIM, both regulators and markers of EMT. We also identified IL-11 as a secondary target of TWF1 in the miR-30c signaling pathway. Expression of miR-30c inversely correlated with TWF1 and IL-11 levels in primary breast tumors and low IL-11 associated with relapse-free survival in breast cancer patients. Furthermore, our study demonstrates that miR-30c is transcriptionally regulated by GATA3 in breast tumors. Identification of a novel miRNA-mediated pathway that regulates chemoresistance and apoptosis in breast cancer will facilitate the development of novel therapeutic strategies.

IDENTIFICATION OF LIN28A-INTERACTING RNAS WITH HITS-CLIP IN HUMAN BREAST CANCER CELLS

Masaki Mori[1], Peng Du[1], Robert Lapierre[1], Stephan Winklmeier[1], Fernando Camargo[2], Richard Gregory[1]
[A]The Stem Cell Program, [B]Division of Hematology/Oncology, [1]Boston Children's Hospital, Boston, MA, United States

LIN28A is an RNA binding protein that regulates stem cell pluripotency, embryonic development and growth, glucose metabolism, and tumorigenesis. A well-characterized molecular function of LIN28A is to selectively regulate

the expression of the let-7 family of microRNAs (miRNAs). Lin28A binds to the terminal loop structure of let-7 precursor miRNAs (pre-let-7) and recruits alternative 3' terminal uridylyl transferases (TUTases) Zcchc11 and/or Zcchc6 (also known as TUT4 and TUT7 respectively). These enzymes catalyze pre-let-7 oligouridylation that inhibits Dicer-mediated processing to the mature let-7 miRNA and promotes pre-let-7 degradation by an unknown nuclease. It is emerging that in addition to controlling let-7 expression LIN28A may have additional gene regulatory roles. Recent reports have identified a large variety of RNAs that associate with Lin28A in different cell types and it appears that Lin28A can either enhance or repress translation of some of the associated messenger RNAs (mRNAs). We previously found that Lin28A is highly expressed in the Her2-overexpressing subset of human breast tumors. Moreover, RNAi-mediated knockdown of Lin28A blocked the
tumorigenic capacity and metastatic potential of Her2-positive human breast cancer cells and xenografts. To gain further insight into the
oncogenic role of Lin28A in breast cancer and to identify possible new
therapeutic targets we sought to identify on a transcriptome-wide scale the
subset of RNAs that are bound by Lin28A in human breast cancer cells. To accomplish this we carried out LIN28A-HITS-CLIP (High-throughput sequencing of RNA isolated by crosslinking immunoprecipitation) using the T47D human breast cancer cell line to isolate RNAs associated with endogenous LIN28A protein. The RNAs we identified include some of the previously reported LIN28A-interacting RNAs such as let-7 miRNA precursors, and RPS13 a ribosomal RNA. This implies that LIN28A might regulate the altered metabolic, proliferative, and differentiation state of a tumor cell through LIN28-let-7 regulatory axis and ribosomal biogenesis. Interestingly our LIN28A-RNA interactome also uncovered previously unreported mRNAs, miRNA precursors, snoRNAs, transcripts of fusion genes, and long non-coding RNAs (lncRNAs). This analysis provides the first step towards a comprehensive view of LIN28A function in breast
cancer. Our most recent functional studies on some of these newly identified Lin28A-associated RNAs and relevance to breast tumorigenesis will be presented.

LIN28 INTERACTS WITH SPECIFIC OCT4 TRANSCRIPT VARIANTS IN MEDULLOBLASTOMA CELLS

Marcia C T Santos[1], Patricia B G Silva[1], Fabio Pohl[1], Luiz O F Penalva[2], Oswaldo K. Okamoto[1]
[1]Bioscience, University of Sao Paulo, Sao Paulo, Brazil, [2]GCCRI Cellular & Structural Biology, UT Health Science Center, San Antonio, TX, United States

Neoplastic stem cells have been identified in a variety of human cancers, in which they are associated with the initial steps of tumorigenesis. The tumor-initiating cell phenotype may result from genetic alterations affecting the expression of critical genes regulating typical stem cell process such as self-renewal and pluripotency. The stem cell protein Lin28 is an RNA binding protein that controls the biogenesis of a group of miRNA, affecting their activity and stability, and expression of a subset of mRNAs at the post-transcriptional levels. LIN28 is ectopically expressed in some malignant tumors and highly expressed in undifferentiated ESCs and plays important roles in development, stem cell maintenance, oncogenesis and metabolism. Lin28 can be found in a variety of complexes including messenger ribonucleoprotein particles (mRNPs), polysomes, p-bodies and stress granules. In a previous study, aberrant OCT4 expression was correlated with poor survival of pediatric patients with medulloblastoma. In this study, Lin28 was found to be associated with RNPs containing OCT4 mRNA promoting its translation in medulloblastoma cells. The human OCT4 gene can potentially encode three spliced variants, designated as OCT4A, OCT4B and OCT4B1. Expression of all OCT4 isoforms was detected in medulloblastoma as in human embryonic stem cells. Interestingly, it was found that LIN28 associates specifically with OCT4A, but not with OCT4B and OCT4B1 transcript variants in medulloblastoma. These findings indicate that the specific interaction between LIN28 and OCT4A may activate pluripotency-related pathways in meduloblastoma cells thereby contributing to tumor aggressiveness.

T-1043

ABCB5 EXPRESSION IN COLORECTAL CANCER CIRCULATING TUMOR CELLS CORRELATES WITH METASTATIC DISEASE PROGRESSION.

Qin Guo, Jie Ma, Brian Wilson, Markus Frank, **Natasha Frank**
Children's Hospital Boston, Boston, MA, United States

Targeted personalized treatment approaches are critical for the development of successful therapies for advanced colorectal cancer (CRC). In this regard, circulating tumor cells (CTC) are of foremost interest as potential predictors of metastatic disease progression and patient therapeutic response. We have previously demonstrated that ATP-binding cassette member B5 (ABCB5) is expressed by cancer stem cells (CSC) in several human malignancies, including CRC, and that ABCB5 identifies therapy-refractory tumor subpopulations in CRC patients that correlate with disease progression. In order to evaluate the potential role of ABCB5 as a clinically relevant CTC marker, we utilized a human-to-mouse xenograft model system to examine the relationship of ABCB5-positive CRC-CTC to CRC metastasis. Human CRC tumor cells were grafted subcutaneously into immunocompromized NSG mice. 7 weeks after xenotransplantation, peripheral blood, lungs and liver were evaluated by qPCR for expression of human ABCB5 and GAPDH mRNAs. Expression analysis of these specimens revealed a significant positive correlation between peripheral blood human ABCB5 mRNA expression and aggregate metastatic disease load as determined by human GAPDH mRNA expression levels in lungs and liver ($r=0.8994$, $P=0.0147$). Remarkably, no significant correlation existed between peripheral blood human GAPDH mRNA expression and metastatic disease load, indicating a unique and essential role of ABCB5-positive CSC-CTC in colorectal cancer progression. Significantly increased peripheral blood ABCB5 expression was also observed in a clinical series of UICC stages I-III colorectal cancer patients ($n=105$) compared to healthy controls ($P<0.001$). Thus, our results identify the CSC antigen ABCB5 as a novel molecular marker of metastasis-associated CRC-CTC and point to potential utility of ABCB5 as a prognostic indicator and predictor of therapeutic response in patients with advanced colorectal cancer.

CURCUMIN ATTENUATES TUMOR INITIATING STEM-LIKE PROPERTY OF HEAD AND NECK CANCER THROUGH MIR145 AXIS-MEDIATED PARACRINE SIGNALING

Shih-Hwa Chiou, Guang-Yuh Chiou
Department of Medical Research & Education, Taipei Veterans General Hospital, Taipei, Taiwan

Recent reports have demonstrated that head and neck cancer derived tumor initiating cells (HNC-TICs) presented high tumorigenic, chemo-radioresistant, metastatic properties, and coupled with gain of epithelial-mesenchymal transition (EMT) characteristics. As curcumin, an active component of the spice turmeric, can exert cytotoxic effects on cancer cells without harming normal tissues. The aim of this study was to investigate the chemo-therapeutic effect and regulatory mechanisms of curcumin on HNC-TICs. We first observed that the treatment of curcumin significantly down-regulated the ALDH1 activity, CD44 positivity, self-renewal property, and side population of HNC cells in a dose dependent manner. Using miRNA/mRNA-microarray analysis, curcumin significantly increased expression of tumor suppressive miR-145. Further mechanistic studies showed that the re-expression of PU-PEI-mediated miR145 delivery led to decreased of TICs properties. Blocking of endogenous miR145 can dramatically enhance stemness and tumor-initiating properties in ALDH1-CD44- non-TICs HNC cells. Additionally, the repressive effect of miR-145 on TICs properties was mediated by regulating of EMT. Importantly, in vivo nude mice model showed that cucumin treatment by oral gavage or PU-PEI-mediated miR145 delivery to xenograft tumors reduced tumor growth and metastasis and prolonged the survival times of tumor-bearing mice. From these results, we conclude that the inhibition of tumor aggressiveness in HNC-TIC in by curcumin was in part was mediated by up-regulation of miR-145, suggesting that curcumin would be a valuable therapeutics clinically in treatment modalities for malignant head and neck cancers by elimination of tumor initiating stem-like, and EMT properties.

T-1045

DNA DAMAGE RESPONSE AND STEMNESS PROPERTIES OF MURINE METASTASTIC TESTICULAR GERM CELL CANCERS

Amy M. Lyndaker, Timothy M. Pierpont, Claire M. Anderson, Donald H. Schlafer, Teresa L. Southard, **Robert S. Weiss**
Dept. of Biomedical Sciences, Cornell University, Ithaca, NY, United States

Testicular germ cell tumors (TGCTs) are the most common cancers of young men. Interestingly, advanced metastatic TGCTs are associated with a remarkably high survival rate following conventional chemotherapy, in contrast to most solid cancers. They are also distinct in that they typically retain functional DNA damage response (DDR) pathways, which could contribute to their responsiveness to genotoxic chemotherapies. To investigate the role of the DDR in the development and treatment sensitivity of TGCTs, we generated a novel mouse model featuring conditional inactivation of the Pten tumor suppressor and activation of the Kras oncogene in pre-meiotic spermatogonia using Cre/loxP recombination. Mice with both Pten deletion and Kras activation (Pten/Kras mice) developed teratocarcinoma, a mixed germ cell tumor containing both teratoma and embryonal carcinoma components. Consistent with these histopathological features, Pten/Kras-induced TGCTs had scattered clusters of cells that expressed Oct4, a pluripotency factor and marker of human embryonal carcinoma. While 70% of Pten/Kras mice developed TGCTs, typically by 4 weeks of age, only 16.7% of Pten single mutants and no Kras single mutants developed TGCTs, highlighting a potent synergy between Pten and Kras in tumor induction. Metastases containing teratoma tissue and in some cases Oct4-positive cells were identified in approximately one-fourth of Pten/Kras mice with primary TGCTs. Interestingly, early neoplasms in this model were nearly devoid of the DNA break marker γ-H2AX, suggestive of distinct DDR properties relative to other solid cancers. Continued analysis of this model holds great promise for elucidating how stem cell properties of the germ cells from which TGCTs arise impact DDR activity during tumor development and therapy, with important implications for the prevention and treatment of a variety of cancers.

T-1046

DRUG RESISTANCE CELLS OF COLON CANCER CELLS PRODUCE CARCINOMA EMBRYONIC ANTIGEN BUT ARE NOT CANCER-INITIATING CELLS

Yi-wei Huang, Chia-Ju Hsu, Li-yu Chen, Yu-Hsuan Chou, Akon Higuchi
Department of Chemical and Materials Engineering, National Central University, Jhongli, Taiwan

Tumors contain a small subpopulation of cancer-initiating cells, known as cancer stem cells (CSCs), that exhibit a self-renewing capacity and are responsible for tumor generation. CSCs are cells that can form tumors while having stem cell properties such as self-renewal and the ability to differentiate into multiple cell types. It is suggested that CSCs persist in tumors as a distinct population and cause relapse and metastasis by giving rise to new tumors. Specific surface markers for colon CSCs have been reported, and CD133 is the most studied surface marker for colon CSCs. Several other colon CSC markers have been proposed; these include: ESA, CD44, CD166, Msi-1, CD29, CD24, Lgr5, and ALDH-1. However, exact and reliable surface markers of colon CSCs have not yet been identified rationally. The only reliable method for identifying and quantifying CSCs is the observation of tumor formation in a serial xenotransplantation model. In this study, we evaluated the higher levels of CEA secreted by the LoVo colon carcinoma cell line, which was cultured in serum-free and serum-containing medium containing anticancer drugs. Drug-resistant LoVo cells were analyzed to determine whether those cells had CSC characteristics, e.g., small size of the cells/colonosphere and strong expression of CSC surface markers, as indicated by flow cytometry and immunohistochemistry analysis. Finally, in vivo tumorigenesis was examined by subcutaneously xenotransplanting the isolated drug-resistant LoVo cells into mice; we then evaluated whether the drug-resistant cells isolated in this study were CSCs. We found that drug-resistant cells, which comprised less than 1% of the LoVo human colon cancer cells that survived in serum-free or serum-containing medium supplemented with drugs (5-fluorouracil, acetylsalicylic acid, oxaliplatin, and cisplatin) were found to produce more than two orders higher than normal levels of carcinoembryonic antigen (CEA) per cell. These results raised the question of whether CSCs could be isolated from drug-resistant colon cancer cells when anticancer drugs are added to the culture medium. The percentage of cells positive for CD133, which is known to be a typical marker of CSCs, decreased in parallel with a decrease in the cell survival rate after the addition of anticancer drugs in both the serum-free and serum-containing media. Drug-resistant LoVo

cells had lower expression of CSC markers, including CD29, CD44, CD166, ALDH-1, Lgr5, and Msi-1, compared with the parental LoVo cells based on immunohistochemical examination. The drug-resistant LoVo colon cancer cells, selected by adding anticancer drugs to the culture medium, showed enhanced production of CEA in both serum-free and serum-containing media; these cells did not behave like CSCs in tumor generation experiments in vivo, even though CSCs have frequently been hypothesized to be drug-resistant.

Chromatin in Stem Cells

EXPLORATION OF CHROMATIN INTERACTIONS IN PLURIPOTENT STEM CELLS

Hiroki Ikeda, Masamitsu Sone, Shinya Yamanaka, Takuya Yamamoto
CiRA, Kyoto Univ., Kyoto, Japan

Genome-wide analysis of histone modifications and electron microscopic observations have suggested that chromatin structures in somatic cell are reorganized during the reprogramming process. However, it remains unclear how chromatin structures affect pluripotency. There is a method which can elucidate the physically neighbouring regions of chromatin loci by proximity-based ligation of the DNA fragments in the interacted chromatin area, called 3C. Currently, by combining massively parallel sequencing, several methods have been invented based on 3C for detection of the genome-wide chromatin interactions. Here, we report the characterization of chromatin interactions in pluripotent stem cells determined by those various methods. First, we have studied higher order chromatin structures in the iPS cells using a 3C-based method, called Hi-C. As a result, we found that inter-chromosomal interactions in ES cells and iPS cells are more diverse than those in somatic cells. Moreover, we also found several different intra-chromosomal interaction areas between iPS/ES cells and somatic cells. To identify chromatin structures associated with the acquisition of pluripotency, we are now developing a new 3C-based method that can intensively analyze chromatin architectures of pluripotency genes and developmental key genes. So far, we detected different gene-loop formations between human iPSCs and somatic cells at several genomic regions (e.g. HOXA loci, etc.).

T-1052

SPATIOTEMPORAL CLUSTERING OF EPIGENOME REVEALS RULES OF DYNAMIC GENE REGULATION

Pengfei Yu[1], Shu Xiao[1], Wei Huang[2], Xiaoyun Xing[3], Chun-Xiao Song[4], Darina Mcdee[1], Tetsuya Tanaka[5], Ting Wang[3], Chuan He[4], Sheng Zhong[1]
[1]Bioengineering, University of California, San Diego, San Diego, CA, United States, [2]Institute of Mathematic and Statistic, Northeast Normal University, Changchun, China, [3]Department of Genetics, Washington University in St. Louis, St. Louis, MO, United States, [4]Department of Chemistry, University of Chicago, Chicago, IL, United States, [5]Institute for Genomic Biology, University of Illinois at Urbana-Champaign, Urbana, IL, United States

Spatial organization of different epigenomic marks was used to infer functions of the epigenome. It remains unclear what can be learned from the temporal changes of the epigenome. Here, we developed a probabilistic model to cluster genomic sequences based on the similarity of temporal changes of multiple epigenomic marks during a cellular differentiation process. We differentiated mouse embryonic stem (ES) cells into mesendoderm cells. At three time points during this differentiation process, we used high-throughput sequencing to measure 7 histone modifications and variants including H3K4me1/2/3, H3K27ac, H3K27me3, H3K36me3, and H2A.Z, 2 DNA modifications including 5-mC and 5-hmC, and transcribed mRNAs and non-coding RNAs (ncRNAs). Genomic sequences were clustered based on the spatiotemporal epigenomic information. These clusters not only clearly distinguished gene bodies, promoters, and enhancers, but also were predictive of bidirectional promoters, miRNA promoters, and piRNAs. This suggests specific epigenomic patterns exist on piRNA genes much earlier than germ cell development. Temporal changes of H3K4me2, unmethylated CpG, and H2A.Z were predictive of 5-hmC changes, suggesting

unmethylated CpG and H3K4me2 as potential upstream signals guiding TETs to specific sequences. Several rules on combinatorial epigenomic changes and their effects on mRNA expression and ncRNA expression were derived, including a simple rule governing the relationship between 5-hmC and gene expression levels. A Sox17 enhancer containing a FOXA2 binding site and a Foxa2 enhancer containing a SOX17 binding site were identified, suggesting a positive feedback loop between the two mesendoderm transcription factors. These data illustrate the power of using epigenome dynamics to investigate regulatory functions.

DIRECTED DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS IS ACCOMPANIED BY WIDESPREAD EPIGENETIC REMODELING AND REVEALS NOVEL PUTATIVE REGULATORY ELEMENTS

Casey Gifford[1], Michael Ziller[1], Cole Trapnell[1], Hongcang Gu[2], Alexander Tsankov[1], Julie Donaghey[1], David Kelley[1], John Rinn[1], Charles Epstein[2], Bradley Bernstein[3], Alexander Meissner[1]
[1]SCRB, Harvard University, Cambridge, MA, United States, [2]Broad Institute, Cambridge, MA, United States, [3]MGH, Boston, MA, United States

Differentiation of human embryonic stem cells (hESCs) provides a unique opportunity to study the epigenetic mechanisms that facilitate cellular transitions. To better understand the molecular basis of lineage specification, we performed comprehensive transcriptional and epigenetic profiling of three populations derived through directed differentiation of hESCs. Genome-wide mapping across these distinct populations, which resemble each of the germ layers found during embryonic development, for a combination of histone marks selected by the NIH Roadmap Epigenomics Project (H3K4me1, H3K4me3, H3K27me3, H3K27ac, H3K36me3, and H3K9me3), DNA methylation through whole genome bisulfite sequencing and RNA sequencing, reveals unique, lineage specific remodeling events. Most events are observed at distal regulatory sites associated with transcription factor binding, and often involve coordinated changes in both the DNA methylation level and enrichment of histone modifications, leading to three distinct epigenomic fates. Our data show gain of H3K27ac after differentiation at regions that have high DNA methylation levels in hESCs rather than H3K4me1 and H3K27me3. We additionally identify a novel dynamic, in which H3K27me3 is gained during differentiation in CpG poor regions that exhibit high levels of DNA methylation in hESCs. Interestingly, we find that this transition is associated with pioneer transcription factor binding sites, such as FOXA2, potentially elucidating an intermediate step in the decompaction of heterochromatin that occurs during the execution of cell fate decisions. Integration of these data sets allowed us to dissect the early events that dictate in vitro specification at high resolution, and in the future may help devise faithful differentiation protocols, leading to the in vitro derivation of therapeutically relevant tissue types.

T-1054

THE ROLE OF HP1α WITHIN HETEROCHROMATIN AND ITS EFFECT ON HUMAN PLURIPOTENT STEM CELLS

Marina Watanabe, Quan Zhu
Salk Institute for Biological Studies, SAN DIEGO, CA, United States

Pluripotent stem cells have the capacity to differentiate into all somatic tissues, and as such, are prized for their promising potential in tissue replacement therapy. Human embryonic stem (ES) cells and induced pluripotent stem (iPS) cells are the most commonly utilized pluripotent cells. Though often mistakenly considered equivalent, the two cell types have numerous differences including the presence of two varieties of iPS cells known as primed and naïve that differ in their pluripotency. The mechanisms behind the establishment and maintenance of pluripotency are not fully understood, but it is known that the epigenetic state of chromatin plays a critical part. Greater understanding of epigenetic mechanisms to control pluripotency and directed differentiation will likely improve their utility and manipulation, as well as interrogate the downstream usefulness of these important cell types in clinical applications. To determine the epigenetic differences among ES cells, primed, naïve iPS cells and somatic cells, we set out to investigate the dynamics and architecture of the silenced chromatin, the heterochromatin. Heterochromatin protein 1 (HP1), due to its role as a key heterochromatin regulator, was used as a marker to visualize

heterochromatin in live-cell and super resolution imaging beyond the optical diffraction limit at the 30nm level. Fluorescence Recover After Photobleaching (FRAP) experiments of HP1-GFP fusions indicate an increased exchange rate of HP1 proteins in hES cells compared to iPS cells, which are more dynamic than fibroblasts. Light sheet super resolution microscopy results suggest a more isotropic distribution of HP1 proteins in human ES and iPS cells than that in somatic cells. In addition, the results of these studies suggest a more open chromatin state in pluripotency with elevated heterochromatin dynamics.

T-1055

KDM2B MAINTAINS MURINE EMBRYONIC STEM CELL STATUS BY RECRUITING PRC1 COMPLEX TO CPG ISLANDS OF DEVELOPMENTAL GENES

Jin He, Li Shen, Ma Wan, olena Taranova, Hao Wu, Yi Zhang
Genetics, Pediatrics, Harvard Medical School, Boston, MA, United States

Polycomb group (PcG) proteins play important roles in repressing lineage-specific genes and maintaining the undifferentiated state of mouse embryonic stem cells (mESCs). However, how PcG proteins are recruited to their target genes is largely unknown. Here, we show that the H3K36-specific histone demethylase Kdm2b is highly expressed in mESCs and regulated by the pluripotent factors Oct4/Sox2 directly. Depletion of Kdm2b in mESCs causes de-repression of lineage-specific genes and induces early differentiation. The function of Kdm2b depends on its CxxC-ZF domain, which mediates Kdm2b's genome-wide binding to CpG islands (CGIs). Kdm2b interacts with the core components of the Polycomb repressive complex 1 (PRC1) and recruits the complex to the CGIs of early lineage-specific genes. Thus, our study not only reveals a novel Oct4/Sox2-Kdm2b-PRC1-CGI regulatory axis and its function in maintaining undifferentiated state of mESCs, but also demonstrates a critical function of Kdm2b in recruiting PRC1 to the CGIs of lineage-specific genes to repress their expression.

T-1056

ROLE OF INNATE IMMUNITY AND CHROMATIN REMODELING IN NUCLEAR REPROGRAMMING

Ji Eun Lee[1], Nazish Sayed[1], Kin Fai Au[2], Wing H. Wong[2], Renee Reijo Pera[3], John P. Cooke[1]
[A]Cardiovascular Medicine, [B]Department of Statistics, [C]Institute for Stem Cell Biology & Regenerative Medicine, [1]Stanford University, Stanford, CA, United States

Recently, we discovered that the viral vectors themselves, carrying the Yamanaka factors, play a critical role in nuclear reprogramming (Lee et al. Cell 2012). In seeking to develop reprogramming approach, we discovered a striking and consistent difference in the pattern of gene expression induced by viral versus protein-based delivery of the reprogramming factors. The difference in the pattern of gene expression suggested to us that a signaling pathway required for efficient nuclear reprogramming was activated by the retroviral, but not CPP approach. We confirmed, that the viral vector was more than a mere vehicle for genes encoding the reprogramming factors. In both gain- and loss-of function studies, we find that activation of toll-like receptor 3 (TLR3) plays a role in the efficiency of nuclear reprogramming. Stimulation of TLR3 causes rapid changes in the expression of epigenetic modifiers, with chromatin remodeling and changes in gene expression, which favor induction of pluripotency. To understand the epigenetic mechanism of innate immunity in reprogramming, we characterize the TLR signaling cascades and epigenetic modifiers that are activated during reprogramming using single cell mass cytometry together with DNA microarray analysis. Next, we determine the effects of innate immunity and the downstream epigenetic modifiers on chromatin modification. Using secondary MEFs that express a doxycycline-inducible cassette encoding the reprogramming factors, we determine epigenetic marks during iPSC derivation in the absence or presence of TLR activation using transcriptional and epigenetic profiling as well as functional assays. These studies highlight the gaps that remain in our understanding of nuclear reprogramming, and for the first time suggest a collaborative contribution of inflammatory pathways in the induction of pluripotency.

T-1057

ABERRANT METHYLATION SPREADING IS DICTATED BY CTG EXPANSION SIZE IN MYOTONIC DYSTROPHY-AFFECTED HUMAN EMBRYONIC STEM CELLS

Shira Yanovsky Dagan[1], Michal Avitzour[1], Moshe Shteiner[1], Gheona Altarescu[2], Paul Renbaum[2], Talia Eldar-Geva[3], Aharon Peretz[3], Stella Mitrani-Rosenbaum[4], Ephrat Levy-Lahad[2], Silvina Epsztejn-Litman[1], Rachel Eiges[1]
[A]Stem Cell Research Laboratory, [B]Medical Genetics Institute, [1]Hebrew University of Jerusalem, Jerusalem, Israel, [2]IVF Unit, Shaare Zedek Medical Center, Jerusalem, Israel, [3]Goldyne Savad Institute for Gene Therapy, Hadassah Hebrew University Medical Center, Jerusalem, Israel

Myotonic dystrophy type 1 (DM1) results from CTG repeat expansions within the 3`UTR of DMPK gene, aberrantly leading to DNA methylation of a CpG island. Here we characterized DNA methylation upstream of the CTGs in undifferentiated cells, explore its effect on local gene transcription and determined whether CTCF binding loss may be mechanistically involved. Using a wide range of 14 different human embryonic stem cells lines derived from DM1-affected embryos as well as DM1 affected iPS cells, we show that abnormal methylation is already established in pluripotent stem cells and is exclusively acquired by expansions of at least 300 CTG copies. The extent of methylation spreading from the upstream flanking region relies on expansion size; the larger the expansion, the more distant methylation extends towards the repeats. This association between expansion size and methylation extent is not detected if studying somatic cells of patients as it is restricted to uncommitted embryonic cells. Interestingly, we show that hypermethylation upstream of the repeats does not affect the expression of DMPK but rather strongly correlates with the reduction in SIX5, a nearby gene which is located immediately downstream to the repeats. In addition, we illustrate that the allele-specific reduction in SIX5 expression cannot be accounted for the binding loss of CTCF near the repeats, as formally suggested. This study emphasizes the power of mutant HESCs in advancing the understanding of the mechanisms underlying DM1 pathogenesis and, on a more general level, provides an excellent model system to study how CpG islands lose protection from DNA methylation under specific pathological conditions.

T-1058

REGULATION OF NEUROGENESIS AND GLIOMAGENESIS BY THE CHROMATIN REMODELDER CHD7

Weijun Feng, Muhammad Amir Khan, Pablo Bellvis, Olga Bernhardt, Haikun Liu
DKFZ, Heidelberg, Germany

Chromatin factors that regulate neurogenesis in the central nervous system remain largely unexplored. Here we demonstrate that the chromatin remodeler CHD7 (chromodomain-helicase-DNA-binding protein 7), a protein frequently mutated in human CHARGE syndrome, is a master regulator of neurogenesis in the mammalian brain. CHD7 is selectively expressed in neurogenic niches in the adult mouse brain, and inactivation of CHD7 in neural stem cells (NSCs) impairs neuronal differentiation and dendritic development. In line with this, CHD7 expression marks a class of human brain tumors with a molecular signature of neuronal differentiation. Strikingly, the CHD7 mutant phenotype in the hippocampal dentate gyrus is rescued by physical exercise. We further identified Sox4 and Sox11 as direct target genes of CHD7 that are responsible for its function in neurogenesis. Our study demonstrates an essential role of CHD7 in neuronal differentiation of NSCs, thus providing new insights into CHARGE syndrome and brain tumors.

T-1061

PHYSIOLOGICAL SIGNIFICANCE OF TET PROTEINS AND 5HMC IN PLURIPOTENCY AND DEVELOPMENT

Meelad M. Dawlaty, Rudolf Jaenisch
Whitehead Institute for Biomedical Research, Cambridge, MA, United States

Tet enzymes (Tet1/2/3) convert 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC) in various embryonic and adult tissues. Although these enzymes have been implicated in promoting DNA demethylation, their physiolo-

gical significance is not well understood. While Tet3 knockout mice die at birth, mice mutant for either Tet1 or Tet2 are viable raising the question whether these enzymes have overlapping roles in development. To investigate the effects of combined deficiency of Tet proteins on pluripotency and development, we have generated a series of embryonic stem cell (ESC) lines and mice deficient for Tet genes individually or in combination. We find that while single deficiency of any of the three genes does not affect ESC self-renewal or pluripotency, combined loss of Tet1 and Tet2 leads to complete ablation of 5hmC in ESCs and causes developmental defects in chimeric embryos. Consistently, Tet1/Tet2 deficiency in mice, although compatible with development, is associated with increased embryonic abnormalities, perinatal lethality and reduced fertility. Our data show that both Tet1 and Tet2 contribute to 5hmC levels during development and their loss, though in part compensated by Tet3, promotes global hypermethylation and compromises imprinting. Moreover, the presence of substantial levels of 5hmC in double mutant embryos and adult mice suggests a significant contribution of Tet3 in hydroxylation of 5mC during development consistent with its role in promoting differentiation.

Pancreatic Cells

T-1063

COMPARATIVE EFFICACY OF HUMAN ADIPOSE TISSUE DERIVED STEM CELLS VERSUS STROMAL VASCULAR FRACTION IN PROTECTION OF ISLET SURVIVAL AND FUNCTION.

Jiyeon Lee, Songcheol Kim
Lab.of Cell Therapy,, Asan Medical Center, Seoul, Korea, Republic of

Islet cell transplantation is much simpler process compared with pancreas organ transplantation. However during process of isolating islets, islets were exposed to damage like mechanical and enzymatic digestion and oxidative stress.These process cause islet degradation and reduce the efficacyof islet cell transplantation.
Adipose tissue-derived stromal vascular fraction(ADSVF) contains multi cellular population like mesenchymal stem cells, endothelial precursor cells and immune regulatory macrophages. Adipose tissue-derived stem cells(ASCs) have immune modulatory properties, release growth factors and have the ability to differentiate into insulin producing cells. In this study, we examined the islet protection efficacy of ASCs and ADSVF *in vitro* and *in vivo*. ASCs and ADSVF were isolated from same donors. Islet were co-cultured with ASCs and AD-SVF. In FACS analysis, ASC and ADSVF showed different expression of surface antigen. The survival and function of islets were assessed by morphologically and by insulin secretion.

T-1064

COLONY FORMING CELLS IN THE ADULT MOUSE PANCREAS ARE EXPANDABLE IN MATRIGEL AND FORM ENDOCRINE/ACINAR COLONIES IN LAMININ HYDROGEL

Liang Jin[1], Tao Feng[1], Hung Ping Shih[2], Ricardo Zerda[1], Angela Luo[1], Jasper Hsu[1], Alborz Mahdavi[3], Maike Sander[4], David A Tirrell[3], Arthur D Riggs[1], Hsun Teresa Ku[1]
[1]City of Hope, Beckman Research Institute, Duarte, CA, United States, [2]University of California - San Diego, La Jolla, CA, United States, [3]California Institute of Technology, Pasadena, CA, United States, [4]University of California, San Diego, La Jolla, CA, United States

The study of hematopoietic colony-forming units (CFUs) using semisolid culture media has greatly advanced the knowledge of hematopoiesis. Here we report that similar methods can be used to study pancreatic colony-forming units (PCFUs). We have developed two pancreatic colony assays that enable quantitative and functional analyses of progenitor-like cells isolated from dissociated adult (2-4 months old) murine pancreas. We find that a methylcellulose-based semisolid medium containing Matrigel allows

growth of duct-like "Ring/Dense" colonies from a rare (1%) population of total pancreatic single cells. With the addition of roof plate-specific spondin 1, a Wnt agonist, colony-forming cells in Ring/Dense colonies can be expanded more than 100,000-fold when serially dissociated and re-plated in the presence of Matrigel. When cells grown in Matrigel are then transferred to a Matrigelfree semisolid medium with a novel laminin-based hydrogel, some cells grow and differentiate into another type of colony, which we name "Endocrine/Acinar". These Endocrine/Acinar colonies are comprised mostly of endocrine- and acinar-like cells, as ascertained by RNA expression analysis, immunohistochemistry, and electron microscopy. Most Endocrine/Acinar colonies contain beta-like cells that secrete insulin/C-peptide in response to D-glucose and theophylline. These results demonstrate robust self-renewal and differentiation of adult PCFUs-Ring/Dense *in vitro,* and suggest an approach to producing beta-like cells for cell replacement of type 1 diabetes. The methods described, which include microfluidic expression analysis of single cells and colonies, should also advance study of pancreas development and pancreatic progenitor cells.

T-1065

EPIGENETIC MODIFICATIONS ARE ASSOCIATED WITH ENHANCED PANCREAS DIFFERENTIATION FROM ENDODERMAL PROGENITOR CELLS

Lei Ying[1], Chenran Xu[2], Ken Zaret[2], Paul Gadue[1]

[1]The Children's Hospital of Philadelphia, Philadelphia, PA, United States, [2]University of Pennsylvania, Philadelphia, PA, United States

Diabetes is a healthcare burden effecting more than 25 million Americans. Diabetes mellitus type 1 which affects 15-20% of these individuals is characterized by a loss of insulin-producing beta cells of the pancreas, leading to insulin deficiency. While transplantation of cadaver islets does have therapeutic benefit, there is a severe shortage of donors. Therefore, in vitro genera functional β-cells from stem cell populations offer a possible alternative. However, embryonic stem (ES) cell-derived pancreatic-like cells typically produce poly-hormonal endocrine cells that are functionally unresponsive. Recently, our laboratory has described the generation of a novel endoderm stem cell population, termed endodermal progenitor (EP) cells, which can self renew and generate functional mono-hormonal beta-like cells in vitro. Recent studies have show that epigenetic modifications can prepattern foregut endoderm lineage specification, especially with regard to the H3K27me3 mark. We find that EP cells only gain the ability to generate mono-hormonal beta cells after several passages in culture, possibly due to establishment of epigenetic changes over time. In this study, we compared genome-wide gene expression profiles and CHIP-seq analysis of H3K27me3 on ES-derived definitive endoderm (DE) and high passage EP cells. Examination of pancreatic specific gene expression found little difference between these populations. Interestingly, we identified an enrichment of H3K27me3 on pancreatic-related genes specifically in EP cells. To determine if these differences have functional significance, we tested several small molecules that can either increase or decrease the H3K27me3 mark by inhibiting EZH2 or JMJD3 during different stages of pancreas differentiation from EP cells. Two EZH2 inhibitors, 3-Deazaneplanocin A (DZNep) and GSK-126, effectively increase the generation of insulin+ cells when given during the differentiation protocol. These treatments had no effect on the generation of mono-hormonal versus poly-hormonal cells. Our results underscored that modulation of epigenetic status can improve the efficiency of differentiation, which may provide a tool for generating functional and transplantable beta-like cells for translational research.

PRODUCTION OF FUNCTIONAL ISLET CELLS FROM hIPSC: A STEP TOWARDS PERSONALIZED NUTRITION.

Filippo De Franceschi[1], Marine Kraus[1], Yuki Ohi[2], Anindita Bhoumik[2], Nicolas Bouche[1], Evert Kroon[2], Olivia G. Kelly[2], Emmanuel E. Baetge[1]

[1]Nestlé Institute of Health Sciences, Lausanne, Switzerland, [2]ViaCyte, Inc., San Diego, CA, United States

A renewable source of human beta cells would greatly benefit both fundamental research and cell therapy. Pioneering work by ViaCyte has shown that pancreatic progenitors can be differentiated from human embryonic stem cells in vitro; the subsequent transplantation of pancreatic progenitors cells in vivo results in functional beta cell production. ViaCyte has now extended their prior work by optimizing their recently published protocol (Schulz et al. 2012 PLoS One) for the differentiation of pancreatic progenitors from a panel of pluripotent stem cell lines, including induced pluripotent stem cells, yielding encapsulated functional beta cells in vivo (See ISSCR ViaCyte poster Y. Ohi et al.). Using these newly established methods, we utilized macro encapsulation technology to complete the differentiation of the IPSC-derived pancreatic progenitors in vivo (undifferentiated iPSC lines provided by Cellular Dynamics Inc.). The progenitors were loaded into devices manufactured with several different membrane types in order to evaluate the best setup for optimal cell survival, vascularization, and functional islet-cell differentiation. The cell-loaded devices were implanted subcutaneously in immunocompromised mice. Animals receiving the encapsulated grafts respond to glucose stimulation and produce human C-peptide (500-1000pM, 30 min post stim., 16 weeks post-engraftment). In summary, we have demonstrated that we can successfully reproduce the ViaCyte in vitro culture system for hiPS cell expansion and differentiation into pancreatic progenitors and in vivo maturation in macro-encapsulated devices into glucose responsive functional islet cells. These results enable development of IPSC-derived humanized pancreatic models for further investigation of genome Vs. function relationships.

ALGINATE ENCAPSULATION AND DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS TO ISLET CELL TYPES

Thomas Richardson[1], Prashant N. Kumta[2], Ipsita Banerjee[1]

[A]Chemical Engineering, [B]Bioengineering, [1]The University of Pittsburgh, Pittburgh, PA, United States

Type 1 diabetes (T1D) is an autoimmune disease affecting a myriad of people worldwide wherein the beta cells of the pancreas are destroyed resulting in insulin dependence. The Edmonton Protocol of islet transplantation affords the feasible option for treatment of diabetes. However shortage of donor islets combined with immune rejection limits islet transplantation from becoming a viable therapy. We propose alginate encapsulation of insulin producing cells derived from human embryonic stem cells (hESC) as a potentially viable therapy for T1D, due to the virtually unlimited supply of hESCs and the immunoisolation capability of alginate capsules.

We developed a stage wise directed differentiation protocol to derive islet-like cells from hESCs. Definitive endoderm was induced with ActivinA and Wnt3Afor 4 days followed by pancreatic progenitor induction with Cyclopamine and Cyclopamine with Retinoic Acid for 2 days each, respectively. Maturation was induced by Nicotinamide for 2 days and Nicotinamide with DAPT for 7 days. A single cell suspension of ROCK inhibitor treated hESCs were suspended in 1.1% Ca alginate and 0.2% gelatin and encapsulation was achieved by drop wise addition into a bath of 100mM $CaCl_2$ with 10mM HEPES. hESCs were encapsulated at 3 different stages: after maturation to islet-like cells, at the definitive endoderm (DE) stage or as undifferentiated (UD) hESCs. The hESCs were continued with the remaining differentiation protocol based on the stage of encapsulation. Islet maturation was analyzed by gene expression of insulin, *MAFA*, glucagon, and *PDX1*. Further characterization was done by immunostaining, flow cytometry, and protein content analysis of islet-specific markers.

Our results to date show that encapsulation of fully matured cells result in low viability, as well as lower gene expression of mature markers compared to cells prior to encapsulation. However, when hESCs derived DE cells were encapsulated and further induced to islet like cells; the cells exhibited strong maturation markers, even higher than parallel tissue culture plastic (TCP) controls. The viability of the encapsulated cells, however, still remained low. Finally, we evaluated the feasibility of encapsulation of UD hESCs and allowing them to progress through all stages

of differentiation under encapsulation. The encapsulated UD hESCs remained viable and grew into large colonies towards the end of the differentiation protocol. While some dead cells were observed initially, large viable colonies were prominent towards the end of the protocol. Very encouragingly, many of the differentiation markers analyzed were even stronger when cells were encapsulated, in contrast to parallel control cells cultured in conventional TCP. To further analyze the maturation of hESCs fully differentiated under encapsulation, we measured the intracellular protein content of the islet-specific hormone c-peptide. The encapsulated cells showed 0.28pg c-peptide /ug total-protein, while TCP controls showed only 0.085pg c-peptide/ug total-protein.
Our results to date indicate that islet-specific maturation of hESCs is not only feasible option in the encapsulated 3D alginate capsule system but is also a configuration that appears to significantly enhance the maturation of hESCs. Further studies are currently underway to understand the mechanism contributing to significant enhancement as well as to test the in-vivo functionality of these cells in diabetic mice.

T-1068

ESTABLISHING A COLONY ASSAY FOR ADULT MURINE PANCREATIC PROGENITOR CELLS WITHOUT CONDITIONED MEDIA AND SERUM

Lena Wedeken, Liang Jin, Tao Feng, Hsun Teresa Ku
Diabetes and Metabolic Diseases Research, Beckman Research Institute of City of Hope, Duarte, CA, United States

In vitro colony assays are invaluable tools to study self-renewal and differentiation of progenitor cells from various tissues. We recently developed a colony assay that allows quantitative and functional analysis of adult murine pancreatic progenitor-like cells in culture. Dissociated single cells from adult pancreas are plated into a semisolid medium containing methylcellulose (a viscous material), Matrigel (for extracellular matrix components), conditioned media, fetal calf serum and growth factors (nicotinamide, exendin4, activin betaB and vascular endothelial growth factor). The semisolid medium restricts cell movement yet permits a cell to self renew, proliferate, differentiate and form a colony. Using this assay, we found that adult murine pancreatic progenitor-like cells are able to give rise to cystic colonies after three weeks in culture. The single cell that initiates and forms a colony is therefore termed a pancreatic colony-forming unit (PCFU). Adult murine PCFUs are able to self-renew and differentiate into cells resembling ductal, acinar and endocrine cells in our colony assay. However, the undefined components in the conditioned media and serum may complicate the examination of molecular mechanisms that govern the self-renewal and differentiation processes of these progenitor-like cells in future studies. We therefore set out to establish a better-defined, serum-free culture condition for our colony assay. We found that replacing the conditioned media and fetal calf serum with epidermal growth factor (EGF), R-Spondin1, Noggin and Serum Replacement (Invitrogen) in our otherwise unchanged assay allowed colony formation. Omission of EGF or nicotinamide abrogated colony formation, suggesting the survival and/or proliferation of PCFUs are dependent on these factors. This new culture condition allowed the differentiation of PCFUs towards all pancreatic cell lineages with R-Spondin1 and Noggin capable of favoring the formation of ductal and endocrine like cells over acinar like cells. In conclusion, this better-defined culture condition is an improvement of our existing pancreatic colony assay and will allow for studying mechanisms of self-renewal and differentiation of adult pancreatic progenitor cells towards endocrine beta cells in future studies.

T-1071

IN-VIVO MATURATION OF HUMAN EMBRYONIC STEM CELLS DERIVED ENDOCRINE PANCREAS IN PERFUSION-DECELLULARIZED PANCREAS

Saik-Kia Goh[1], Suzanne Bertera[3], Ipsita Banerjee[2]
[1]Univ of Pittsburgh, Pittsburgh, PA, United States, [B]Department of Chemical and Petroleum Engineering, [1]Univ of Pittsburgh, Pittsburgh, PA, United States, [2]Division of Immunogenetics, Department of Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA, United States

Introduction: Type I Diabetes affects over 1 million people in the United States. Embryonic stem cells (ESC) have emerged as an alternative cell source to transplanting donor islets owing to its virtually unlimited replicative capacity and the potential to differentiate into islet-cells. However, ESC derived islet-cells are currently limited by their immature phenotype and functionality. Success with maturation is only achieved after transplantation into animal model to promote full differentiation. Governed by the understanding that the pancreatic matrix plays a significant role during islet development and maturation, we hypothesize that three-dimensional (3D) extracellular matrix (ECM) derived from native pancreas will provide an optimal microenvironment for functional maturation of hESCs, and will serve as a suitable scaffold for implantation.
Materials and Method: Cadaveric pancreata were isolated from adult mice (n=8) and decellularized via detergent (0.5% SDS) perfusion. Resulting pancreatic matrix was characterized for acellularity, preservation of ECM and feasibility to transplant for *in vivo* use. For recellularization, β-cell (MIN6, $30x10^6$ cells) was first seeded into decellularized pancreas. Insulin gene expression was evaluated after 5 days of *ex vivo* culture in perfusion bioreactor (n=3). For hESC differentiation, decellularized pancreas was seeded with hESC-derived definitive endoderm (DE) cells ($30x10^6$ cells) and differentiated into pancreatic progenitor (PP) cells by sonic hedgehog inhibition (cyclopamine) and retinoic acid induction. The PP cell-laden scaffolds were then implanted under kidney capsule of immunodeficient mice for *in vivo* maturation. PP cells implanted without scaffold served as controls (n=3). The recellularized constructs were evaluated via quantitative RT-PCR and immunostaining for pancreatic maturation markers and human C-peptide respectively.
Results and Discussion: Perfusion-decellularization of pancreas with 0.5% SDS resulted in complete removal of cells. Characterization of the decellularized pancreas revealed preservation of ECM and 3D architecture. Implantation of decellularized pancreas induced tissue remodeling but did not elicit adverse immune response. MIN-6 cultured in pancreatic constructs demonstrated higher upregulation of INS1 and INS2 gene expression compared to MIN-6 cultured on fibronectin, collagen I and IV surfaces ($P<0.05$). Repopulation and *in-vitro* differentiation of hESC-derived DE cells in decellularized pancreas showed 52.7±10.8 fold increase in PDX1 compared to Matrigel ($P<0.05$). *In vivo* maturation under kidney capsule after 8 weeks supported full differentiation of the seeded hESC into C-peptide expressing cells. Immunostaining showed that engrafted cells were also positive for NKX6.1, PDX-1 and co-localized with human nuclear antigen staining – confirming the matured β-cells were derivatives from the implanted hESC seeded pancreas graft.
Conclusion: Perfusion decellularized pancreas promotes β-cell function, and provides a favorable microenvironment for pancreatic differentiation when seeded with hESC-derived DE cells. The cell-laden matrices can be transplanted *in vivo* and successfully matured into insulin-producing cells. Transplantation into immunodeficient mice with streptozotocin-induced diabetes is underway to evaluate the therapeutic potential of the hESC-derived endocrine pancreas to achieve normoglycemia.

T-1072

DERIVATION, DIFFERENTIATION, AND GROWTH OF DEFINITIVE ENDODERMAL CELLS FROM REPROGRAMMED DONOR FIBROBLASTS

Casey Roberts[1], Rebecca Ogle[2], Silvia Chen[2], Patrick Sachs[2], Roy Ogle[3]
[1]Regenerative Medicine, Eastern Virginia Medical School, Norfolk, VA, United States, [2]Regenerative Medicine Institute, LifeNet Health, Virginia Beach, VA, United States, [3]Health Sciences, Old Dominion University, Norfolk, VA, United States

Objective
The objective of this study was to differentiate, grow, and maintain the endodermal gene expression of induced pluripotent stem (iPS)-derived definitive endodermal (DE) cells in culture.
Methods
Induced pluripotent stem cells created from BJ neonatal fibroblasts (Stemgent) and F13 adult fibroblasts (from dermal tissue donated for research to LifeNet Health and reprogrammed by StemGent) were cultured on Matrigel (BD Biosciences) with TeSR2 medium (StemCell Technologies) until ready for differentiation. For induction into the

DE lineage, the iPS cells were maintained in DE medium (RPMI-1640, (Invitrogen), 11.1mM L-glutamine (Invitrogen), 1% ABAM (Invitrogen), 0.2% FBS (Gibco), 100nM IDE-1 (StemGent)) for 3 days. The iPS-derived DE cells then were cultured for 7 days in one of the following: DE Step medium (RPMI-1640, 11.1mM L-glutamine, 0.2% FBS (Invitrogen), 1% ABAM, and 50ng/mL Activin A), B27 medium (RPMI, 11.1mM L-glutamine, 1% ABAM, 1X B27, and 50ng/mL Activin A), or IDE-1 medium (RPMI, 11.1mM L-glutamine, 1% ABAM, 1X B27, and 100nM IDE-1). At the beginning and end of the 7 days post-differentiation culture, mRNA was extracted from the cells and assayed for pluripotency and DE gene expression by qPCR and compared to the original fibroblast and iPS cell lines.

Results

The BJ fibroblast and F13 fibroblast-derived iPS cells expressed pluripotency genes (Sox2, Oct 3/4, and Nanog) and the surface marker, Tra-1-81. After differentiating the cells with DE media, the cells' expression of pluripotency genes diminished compared to the iPS cells, while expression of genes associated DE, Sox 17, HNF4A, and FOXA2, increased. The DE cells also showed a decrease in ectodermal and mesodermal gene expression versus the embryoid body-derived cells.

The DE cells were cultured for one week in either DE Step medium or B27 medium, and the cells were assayed for expression of markers of pluriopotency, ectoderm, mesoderm, and DE. The DE Step medium and the B27 medium were found to maintain the DE gene expression by the differentiated cells for one week in culture, while suppressing expression of the genes associated with pluripotency, ectoderm, and mesoderm.

ConclusionThe B27 medium was able to maintain the differentiated DE-derived from BJ and F13 iPS cells. The BJ and F13 iPS cells were differentiated into DE cells with concomitant reduction in expression of pluripotency genes. The DE cells were able to maintain a steady state DE gene expression level for one week in culture, without an increase in gene expression of other cell types. The DE intermediary cells should prove useful for further differentiation into cell types derived from DE such as pancreatic β cells.

INSM1 IS ESSENTIAL FOR THE MAINTENANCE OF MATURE PANCREATIC BETA CELLS

Shiqi Jia[1], Andranik Ivanov[2], Mathew Poy[3], Florian Paul[4], Matthias Selbach[4], Carmen Birchmeier[1]

[A]Developmental Biology/Signal Transduction, [B]Systems Biology of Gene Regulatory Elements, [C]microRNA and Molecular Mechanisms of Metabolic Diseases, [D]Cell Signalling and Mass Spectrometry, [1]Max-Delbrueck-Center for Molecular Medicine (MDC), Berlin, Germany

One goal of stem cell research is to generate medical replacement cells/organs for patients, for instance the pancreatic β cells. In vitro generated pancreatic β cells however are functional immature. A better understanding of the mechanisms of pancreatic β cells maturation is important for generating final replacement β cells. Insm1 (Insulinoma-associated 1), encodes a zinc finger protein, expressed in developmental endocrine and nerve systems and continuously expressed in mature endocrine cells. Null mutation of Insm1 is lethal, with a phenotype of no insulin positive β cells formation in pancreas, while the precursor cells are accumulated. In this study, we showed that Insm1 is essential for the maintenance of mature pancreatic β cells in vivo. Conditional mutation of Insm1 in pancreatic β cells at adult stage resulted an impaired regulated insulin secretion, which is similar as that in immature pancreatic β cells. We further showed the molecular mechanism of Insm1 function i.e. the gene expression pattern, the interaction factors and genome wide DNA binging. More details will be shown on site.

MANIPULATING THE CELL FATE OF STEM CELL DERIVED PANCREATIC PROGENITORS USING MODIFIED RNA

Felicia Walton Pagliuca[1], Jeffrey Millman[1], Wataru Ebina[2], Derrick Rossi[2], Douglas Melton[1]

[1]Harvard Stem Cell Institute, Harvard University, Cambridge, MA, United States, [2]Immune Disease Institute, Children's Hospital Boston, Boston, MA, United States

Pancreatic β cells control mammalian metabolism through glucose-mediated insulin secretion. Since loss or dysfunction of these cells results in diabetes, new sources of β cells would provide a novel therapeutic option for treating diabetes and preventing its complications. Pluripotent stem cells are a promising new source of replacement tissue, if tissue-specific differentiation can be recapitulated in vitro. During pancreatic β cell development, pluripotent stem cells differentiate into increasingly specialized cells characterized by the expression of master regulators like Sox17 in definitive endoderm and Pdx1 in subsequent pancreatic progenitor cells. Although cocktails of small molecules and growth factors can induce a subset of key transcription factors in cells derived from human embryonic stem (hES) cells, this approach has not yet generated functional beta cells in vitro. Direct genetic manipulation with modified RNA has been suggested as an alternative strategy for controlling cell fate conversion. Herein we report the generation of methods to transfect various modified RNA transcripts encoding pancreatic transcription factors into stem cell-derived pancreatic progenitors in order to impose specific cell fate changes. These experiments have shown that a single, transient pulse of Ngn3 RNA can increase the efficiency of endocrine induction in ES-derived pancreatic progenitors by 300%. We have also identified transcription factors that act synergistically with Ngn3 in vitro, including Rfx6 and Hnf1a, to induce β cell fate. Additional studies have revealed that a short temporal window exists within current pancreatic directed differentiation protocols in which Ngn3 is optimally capable of inducing insulin-expressing β cells relative to other islet cell types. Further work evaluating whether transfection of ES-derived endocrine cells with transcription factors normally found in mature beta cells can improve their function in vitro and how these cells perform in vivo in animal models is underway. Taken together, these results suggest that modified RNA transfection is a powerful new tool to control hES-derived β cell fate.

HEPATOCYTE-LIKE CELLS GENERATED FROM MODIFIED MRNA-DERIVED HUMAN INDUCED PLURIPOTENT STEM CELLS

Anna-Karin M. Sjogren[1], Tommy B. Andersson[1], Gabriella Brolén[2]
[A]Cardiovascular and Gastrointestinal Innovative Medicines DMPK, [B]Discovery Sciences Innovative Medicines Assay Development, [1]AstraZeneca R&D, Mölndal, Sweden

Background: Hepatocytes derived from human induced pluripotent stem cells (iPSCs) may be an attractive alternative source of liver cells for cellular transplantation therapy, however safety is a major concern; requiring iPSCs that have been produced without the use of viral transgenes. It has been shown that modified mRNAs can be used to efficiently reprogram somatic cells into iPSCs that are non-viral and transgene-free. *Aim:* The aim of this study was to use modified mRNAs to produce human iPSCs, differentiate these into hepatocyte-like cells and define their hepatic functionalities. *Results:* We reprogrammed human foreskin fibroblasts into iPSCs by transfections with modified mRNAs encoding *OCT4*, *KLF4, SOX2, LIN28* and *c-MYC*, adopted the resulting iPSCs to grow as single cells in a monolayer and subsequently differentiated them into hepatocyte-like cells using a serum-free, three-step protocol. The hepatocyte-like cells exhibited inducible cytochrome P450 enzyme activity, displayed hepatocyte-like morphology, expressed hepatocyte specific genes and proteins and had the ability to store glycogen. *Conclusion:* The single-cell culture of modified RNA-derived induced pluripotent stem cells allows rapid production of large amounts of non-viral, integration-free hepatocyte-like cells, which makes it a promising approach not only for regenerative medicine applications, but also screening assays in the pharmaceutical industry.

T-1082

AN INDUCED PLURIPOTENT STEM CELL MODEL TO STUDY MECHANISMS OF NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) ASSOCIATED WITH PNPLA3 POLYMORPHISMS

Nidhi P. Goyal, Paulina Ordonez, Lawrence SB Goldstein
University of California, San Diego; Sanford Consortium for Regenerative Medicine, La Jolla, CA, United States

Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease in the adult and pediatric population. NAFLD has significant public health implications as it has multiple associated co-morbidities including obesity, hypertension, type 2 diabetes, and cardiovascular disease, all of which increase the risk of premature death. NAFLD denotes a histological spectrum of disease ranging from macrosteatosis, excess accumulation of triglycerides in the liver, to steatosis with inflammation, to fibrosis. NAFLD can lead to hepatocellular carcinoma as well as end-stage liver disease ultimately requiring liver transplantation. NAFLD is a complex disease that has both environmental and genetic components. Genome-wide association studies (GWAS) have recently identified a polymorphism in the gene *PNPLA3* that has a strong association with risk and severity of NAFLD. The variant allele of *PNPLA3* is associated with more severe biochemical and histological abnormalities of NAFLD. The protein product of *PNPLA3*, or adiponutrin, is involved in lipid metabolism, but its exact function in humans remains unclear. The pattern of expression of adiponutrin is different in mice and humans, making it difficult to extrapolate findings from animal models. We are designing isogenic lines of human induced pluripotent stem cells (hIPSC) from a known genetic background with the variant and wild type homozygous alleles of *PNPLA3* using TAL effector nuclease (TALEN) technology. We have designed TALENs specific to the *PNPLA3* SNP and are generating lines of hIPSCs. We have adapted a protocol to induce differentiation of hIPSC to hepatocyte like cells (HLC) to test the hypothesis that polymorphisms of *PNPLA3* induce abnormal lipid processing as a potential initiating event in NAFLD. We will test this hypothesis by studying patterns of lipid metabolism and distribution in hIPSC derived HLCs with the wild type and variant alleles of *PNPLA3*, and the effects that aberrant lipid processing may have on cellular disposal and stress pathways. This approach translates a population-based GWAS into an *in vitro* human model to study the pathophysiology of NAFLD at a fundamental level. More broadly our work is an example of how the combined use of hIPSC technology and targeted genome editing can serve as a strategy to model complex sporadic diseases.

T-1083

PUTATIVE ISOLATION AND CHARACTERIZATION OF LIVER PROGENITOR CELLS FROM ADULT MOUSE

Bin Li, Craig S. Dorrell, Pamela S. Canaday, Carl Pelz, Markus Grompe
Oregon Stem Cell Center, Oregon Health and Sciences University, Portland, OR, United States

Hepatocytes are good candidates for liver failure rescue and liver reconstruction. However, due to the shortage of donor hepatocytes, liver stem cells, which can differentiate into hepatocytes, are in needed. To seek the liver stem cells in the normal adult liver is to be answered. In our lab, we have isolated clonal progenitor cells with cell surface markers MIC1-1C3, CD133 and CD26 from both normal and injured mouse liver. Here, in our study, by way of flow cytometry based antibody screening, we subdivided MIC1-1C3+CD133+CD26-CD45-CD31-CD11b- ductal liver non parenchymal cells (NPCs) with another cell surface marker. RNA sequencing data revealed novel stem cell expressing genes in this cell fraction and the inter action between progenitor cells and other cells in liver. Three dimensional organoid culture and single organoid assay demonstrate that this kind of cell has high proliferative capability, clonal forming efficiency and replating capability. In two-dimensional culture, the liver progenitor derived organoids demonstrated hepatocyte morphology. These liver progenitor cells will be used for transplantation into liver damaged immunodeficient mouse model to define the liver repopulation capability.

T-1084

EFFICIENT DRUG SCREENING AND GENE CORRECTION FOR TREATING LIVER DISEASE USING PATIENT-SPECIFIC STEM CELLS

Su Mi Choi[1], Yonghak Kim[1], Joong Sup Shim[2], Joon Tae Park[4], Rui-Hong Wang[5], Jun O. Liu[2], Chu-Xia Deng[5], Zhaohui Ye[3], Yoon-Young Jang[1]
[A]Department of Oncology, [B]Department of Pharmacology and Molecular Sciences, [C]Institute for Cell Engineering, [1]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [2]Department of Surgery and the McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD, United States, [3]Genetics

of Development and Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, United States

Patient-specific induced pluripotent stem cells (iPSCs) represent a potential source for developing novel drug- and cell- therapies. Although increasing numbers of disease-specific iPSCs have been generated, there has been limited progress in iPSC-based drug screening/discovery for liver diseases, and the low gene targeting efficiency in human iPSCs warrants further improvement. Using iPSC lines from patients with alpha-1 antitrypsin (AAT) deficiency, for which there is currently no drug- or gene- therapy available, we established a platform to discover new drug candidates and to correct disease-causing mutation with a high efficiency. A high-throughput format screening assay based on our hepatic differentiation protocol was implemented to facilitate automated quantification of cellular AAT accumulation using a 96-well immunofluorescence reader. To expedite the eventual application of lead compounds to patients, we conducted drug screening utilizing our established library of clinical compounds, the Johns Hopkins Drug Library, with extensive safety profiles. Through a blind large-scale drug screening, five clinical drugs were identified to reduce AAT accumulation in diverse patient iPSC-derived hepatocyte-like cells. In addition, using the recently developed transcription activator-like effector nuclease (TALEN) technology, we achieved high gene targeting efficiency in AAT-deficiency patient iPSCs with 25-33% of the clones demonstrating simultaneous targeting at both diseased alleles. The hepatocyte-like cells derived from the gene-corrected iPSCs were functional without the mutant AAT accumulation. This highly efficient and cost-effective targeting technology will broadly benefit both basic and translational applications. Conclusions: Our results demonstrated the feasibility of effective large-scale drug screening using an iPSC-based disease model and highly robust gene targeting in human iPSCs; both of which are critical for translating the iPSC technology into novel therapies for untreatable diseases.

T-1085

INDUCTION OF PLASTICITY IN CD14+ CELLS ISOLATED FROM HUMAN PERIPHERAL BLOOD.

Jashdeep Bhattacharjee, Barun Das, Asok Mukhopadhyay, Pramod Upadhyay
PDC, National Institute of Immunology, New Delhi, India

Stem cells are the class of undifferentiated cells which have the potential to differentiate to various cell types. In many clinical conditions, stem cells are used as a part of cell based therapy. In most of the cases the stem cells are being procured from human cord blood or bone marrow of healthy donor. This often leads to immune rejection of the grafted cells by the host immune system thereby compromising the health of the patients. Autologous transplantation would have been the best therapeutic alternative in such cases. Isolating therapeutically significant number of bone marrow stem cells from a patient may compromise his/her health condition. It is the need of the hour to find a class of cell which have relatively higher abundance than stem cells, convenient to procure and last but not the least, have the potential to differentiate to cells of different lineage.
In the current study, **CD14+** cells isolated from the human peripheral blood were reprogrammed to induce plasticity in them so that they acquire the potential to differentiate cells of different lineage. The reprogrammed cells, called **Reprogrammed Monocyte(RM),** shows **downregulation** of CD14 surface marker and **upregulation** hematopoietic stem cell surface marker such as CD34, c-kit. RM has also shown to express **Nanog,** an embryonic transcription factor.
RM was cultured in hepatocyte differentiation media to generate hepatocyte-like cell in vitro, termed as **Neo-hepatocyte**. After 11 days of culture, Neo-hepatocytes were examined for the presence of albumin and HNF4α by **qRTPCR** and **immune cyto-chemistry**. Neo-hepatocytes showed expression of **albumin** and **HNF4α**. Unlike CD14+ cells (Day 0) and RM, Neo-Hepatocytes were able to metabolize **7-pentoxy resorufin** to **resorufin** (PROD Assay) which indicates the expression of **P450** enzymes by these cells.
The in vivo differentiation capability of RM is currently underway.

A SYSTEMS BIOLOGY APPROACH TO GUIDE DIRECT CONVERSION STRATEGIES AND ASSESS CELL IDENTITY

Samantha A. Morris[1], Patrick Cahan[1], Hu Li[2], Emma C. Fink[1], Chloe E. Reichel[1], James J. Collins[2], George Q. Daley[1]
[1]Boston Children's Hospital, Harvard Medical School, Boston, MA, United States, [2]Department of Biomedical Engineering and Center for BioDynamics, Boston University, Boston, MA, United States

Many human diseases such as heart failure, diabetes and neurodegenerative disorders result from the deficiency or dysfunction of critical cell types. Strategies for therapeutic tissue repair or transplantation entails the in vitro manufacture of clinically relevant quantities of defined cell types. The generation of otherwise inaccessible cells also permits disease modeling, toxicology testing and drug discovery in vitro. While engineered cells are often assayed functionally, the equivalence of the derived cells to in vivo cell types is not determined in a standard or comprehensive manner. To address this issue, we developed CellNet, a computational platform that classifies derived cells according to their transcriptional resemblance to a reference data set collated from a range of unique cell types and tissues. We reconstructed the context-dependent transcriptional regulatory networks underlying these cell types and tissues, allowing us to reveal precise regulatory nodes at which derived cells differ from their in vivo counterparts. We have used the platform to assess whether complete cell conversion has been achieved and to identify the cascade of regulatory events that characterize three distinct examples of fate conversion: reprogramming to pluripotency, direct conversion of B cells to macrophages, and direct conversion of fibroblasts to hepatocyte-like cells (HLCs). In experiments to replicate the transcription factor-mediated conversion of fibroblasts to HLCs, our application of CellNet revealed the existence of aberrant endoderm patterning in HLCs, and by identifying the regulatory nodes at which HLCs differ from primary hepatocytes, suggested a modified strategy to better recapitulate the target cell type, which we subsequently confirmed via in vitro functional assays. CellNet thus represents both an analytic and diagnostic algorithm for guiding direct conversion strategies and assessing the fidelity of conversion by detecting gene regulatory networks that define cell identity.

T-1087

PROTOPORPHRIN IX ACCUMULATION IN ABCG2-DEFICIENT LIVER IMPAIRS MITOCHONDRIAL DYNAMICS AND DIFFERENTIATION POTENTIALS OF HEPATIC STEM/PROGENITOR CELLS

Hsiao-Min Chang[1], Yu-Hsing Lin[1], Fang-Pei Chang[1], Chia-Rui Shen[2], Chao-Lin Liu[3], Wan-Yu Mao[1], Chia-Ning Shen[1]
[1]Genomic Research Center, Academic Sinica, Taipei, Taiwan, [2]Department of Medical Biotechnology and Laboratory Science, Chang Gung University, Tao-Yuan, Taiwan, [3]Ming Chi University of Technology, New Taipei City, Taiwan

The ATP binding cassette transporter ABCG2 are found to express in a wide variety of stem cells and in several somatic tissues including liver. Our recent work showed that ABCG2 is involved in regulating porphyrin homeostasis of embryonic stem cells and accumulation of protoporphyrin IX induced by ABCG2 inhibition affect self-renewal of ES cells. However, the physiological role of ABCG2 in somatic tissues and stem cells is largely unclear. Here, we generated ABCG2 knock mice and showed that ABCG2-knockout in hepatocytes elevated levels of protoporphyrin IX and impaired mitochondrial dynamics and function. Either treatment of 5-Aminolevulinic acid or functional blockage of ABCG2 transporter with fumitremorgin C (FTC), a specific and potent inhibitor of ABCG2, which elevated the cellular level of protoporphyrin IX, disrupted mitochondrial fusion/fission balance in hepatocytes. We assume impairment in mitochondrial dynamics affecting differentiation capability of hepatic stem/progenitor cells. We further demonstrated that hepatic stem/progenitor cells could be activated in mice treated 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC). And these activated hepatic stem/progenitor cells could therefore replenish damaged hepatocytes. However, we found that knockout of ABCG2 affected liver repairing mediated by hepatic stem/progenitor cells. The results suggest mitochondrial dynamics connected to differentiation of hepatic stem/progenitor cells and ABCG2 transporter protects liver from protoporphyrin IX accumulation which allows differentiation-driven mitochondrial remodeling during liver repair.

GROWING SURROGATE LIVER IN A NEW SWINE MODEL OF LIVER DISEASE

Junji Komori[1], Paulo Fontes[2], Eric Lagasse[1]
[A]Pathology, [B]Surgery, [1]Univ of Pittsburgh, Pittsburgh, PA, United States

Stem cell therapy has been viewed as a promising alternative to organ transplantation. However, for some patients, orthotopic cell-based therapy directed at a diseased organ may not be feasible for many reasons, ranging from a possible lack of an appropriate environment in cirrhotic and fibrotic liver during end-stage disease to the lack of a thymus in complete DiGeorge Syndrome. Consequently, a critical component of cell-based therapy for these patients is to establish an optimal in vivo site for cell and tissue transplantation to restore organ functions. We have previously demonstrated that primary hepatocytes injected directly into a single lymph node (LN) will generate an ectopic liver and rescue a tyrosinemic mouse model from lethal liver failure. Furthermore, we have demonstrated that murine LNs provide a beneficial environment for ectopic transplantation of other cell types such as thymic epithelial cells and pancreatic islets. To validate the clinical relevancy and feasibility of generating an ectopic liver in patients with liver disease, we generated a swine model of liver disease. After total portacaval shunts and hepatectomy, an autologous population of hepatocytes isolated from the removed lobe was transplanted back in the LNs of the animal. 1-2 months later, autopsies were performed. Almost all of the injected LNs demonstrated hepatocytes engraftment with vascularization.
Here, we provide the first report describing the use of a LN as a site for liver cells transplant and demonstrating definitely visible engraftment in a large animal model. This approach is providing a new concept to use the LN as an in vivo bioreactor in which to regenerate functional organs.

LIVER REPOPULATION IN A DIPHTHERIA TOXIN-INDUCED LIVER DAMAGE MODEL WITH HUMAN PROLIFERATIVE HEPATOCYTES

Ranran ZHANG[1], Yunwen ZHENG[1], Takanori Takebe[1], Tomonori Tsuchida[1], Bin Li[2], Yasuharu Ueno[1], Hideki Taniguchi[1]
[1]yokohama city university, yokohama, Japan, [2]oregon health and science university, oregon, OR, United States

Background
Hepatocytes transplantation was considered as an alternative therapy for liver dysfunction including acute liver failure and metabolic disorders; however, this promising method was impeded by donor cell shortage and validation. Since human adult hepatocytes with scarce cell source loss of in vitro proliferation capability and have unstable validation, the cost of human adult hepatocytes transplantation was improved; therefore, human proliferative hepatocytes including human fetal liver cells (hFLC) and human hepatic stem cells (hHSC) transplantation was set to be used for overcoming those issues with vividly in vitro proliferation property and low cost. This study introduced a novel mouse model of Albumin-TRECK/SCID (TRECK: Toxin Receptor Mediated Cell Knockout) to generate humanized livers and provide in vivo differential microenvironment for donor cells.
Methods and Results
1.5ug/kg DT (diphtheria toxin) was administrated into 6-week old mouse, mouse hepatocytes in albumin-TRECK/SCID mouse liver were ablated within 72hrs, after mouse GOT/AST, GPT/ALT were analyzed, a million of donor cells were transplanted into liver damaged mouse. About 6 weeks later, albumin-TRECK/SCID mouse with human heaptocytes was scarified for human albumin concentration detection, immunostaining, human gene analysis, replacement rate calculation and other assays. Showed both of the transplanted hFLC and hHSC were succeed in generating humanized livers by albumin-TRECK/SCID mouse, the chimerism in albumin-TRECK/SCID mouse reached as high as 90%. Comparing with hFLC transplanted humanized mouse group, the hHSC derived humanized mouse had higher human albumin secretion also with better induction and differentiation; the induction effect of human albumin expression could reach over 1.5x105-folds higher than donor cells, to hCYP3A4, hCYP2C9, hCYP2C19, the highest induction effect were about 2.2x105, 0.8x105, 1.3x105 folds separately.
Conclusion

We successfully constructed humanized liver in albumin-TRECK /SCID mouse with human proliferative hepatocytes like hFLC or hHSC, and this humanized mouse may prospectively bring more functional applications such as drug metabolism; drug to drug interaction and other in vivo or in vitro studies.

DIRECT INDUCTION OF HEPATIC PROGENITOR-LIKE CELLS FROM MOUSE FIBROBLASTS BY REPROGRAMMING FACTORS

Maiko Higuchi[1], Norihisa Furukawa[2], Katsuhisa Tashiro[2], Kenji Kawabata[2], Kazufumi Katayama[1], Masashi Tachibana[1], fuminori Sakurai[1], Hiroyuki Mizuguchi[1]

Efficient differentiation of functional hepatocyte-like cells from other somatic cells could provide not only a valuable system for drug cytotoxicity and metabolism screening, but also a potential source of hepatocytes for regenerative therapy. Induced hepatic differentiation has been previously achieved using induced pluripotent stem cells (iPSCs). However, these protocols require two processes including fibroblasts into pluripotent state using four reprogramming factors (Oct3/4, Sox2, Klf-4 and c-Myc) and then differentiating them into the desired hepatocytes. This requires time-consuming and is not so efficient. Here, we report direct induction of expandable hepatic progenitor-like cells from mouse fibroblasts without forming iPSCs.
For reprogramming studies, we used mouse embryonic fibroblasts (MEF) from alpha-fetoprotein (AFP)-GFP transgenic mouse embryos at day E13.5 to monitor conversion into the hepatic lineage. To induce partially reprogrammed state, AFP-GFP MEF were transduced with lentivirus encoding four reprogramming factors and then cultured in reprogramming media for 5 days. From day 6, these cells were cultured in chemically defined medium containing BMP4 and FGF4 for differentiation into hepatocytes. At day 14, after transduction with lentivirus vectors, a small number of GFP-positive cells were observed, whereas no GFP-positive cells were observed in the MEF transduced with control lentivirus vectors. To determine whether these cells were hepatocyte lineage or not, GFP-positive cells on 21 days after transduction were sorted and analyzed for gene expression of hepatocyte lineage markers. GFP-positive cells expressed not only hepatic lineage marker, such as AFP and ALB, but also cholangiocyte marker, CK7. However, more mature markers, ASGPR1 and TO, were not expressed in GFP-positive cells. After replating, many GFP-positive colonies appeared and could be expanded during several passages with expression of hepatic lineage markers. GFP-positive cells show significant self-renewal potential and the morphology was gradually changed into that of hepatocyte progenitors. Moreover, these hepatic progenitor-like cells could differentiate into more mature hepatocytes by elongating culture with the above-mentioned medium containing dexamethasone and HGF for 5 days. These cells showed multiple hepatocyte specific features; expression of ALB and E-cadherin and the abilities to uptake indocyanine green and to store glycogen.
In summary, we have shown that overexpression of four reprogramming factors in fibroblasts and cultivation with defined media for differentiation into hepatocytes can give rise to rapidly generate hepatic progenitor-like cells without going through iPSCs state. Moreover, induced hepatic progenitor-like cells showed significant self-renewal potential. Therefore, our protocol may offer a benefit to rapidly generate a large number of hepatocyte-like cells for clinical application as well as for drug screening assay.

CYTOKINE-DIRECTED DIFFERENTIATION AND IN VITRO EXPANSION OF HEPATIC HIPSC AND HESC DERIVATIVES

Malte Sgodda, Jeannine Hoepfner, Susanne Alfken, Tobias Cantz
Hannover Medical School, Junior research group stem cell biology, Hannover, Germany

Human embryonic stem cells (hESCs) and human induced pluripotent stem cells (hIPSCs) hold great promise in regenerative medicine. Hepatic differentiated pluripotent stem cells might serve as hepatic transplants for metabolic or acute liver diseases. So far, hepatic differentiation efficiencies of hiPSCs and hESCs are well studied, but enrich-

ment of functional active hepatic derivatives and a sufficient homogenous population for transplantation purposes need further attention.
In our study, we aimed for an efficient protocol that is applicable to differentiate both, hESCs and hiPSCs into an expandable definitive endodermal progenitor lineage. We were using a cytokine- and small molecule-based protocol stimulating the WNT pathway for direct differentiation of hESC and hiPS cells into a definitive endoderm progenitor population. Next, we sorted CD117 (c-Kit) and CD184 (CXCR4) double positive cells by flow cytometry and replated these cells for further propagation in a co-culture system with mouse fibroblasts. These endodermal progenitor cells were passaged up to 20 doublings and analysed each passage. The differentiation status during the passages was determined by qRT-PCR for the endodermal markers SOX17, FOXA2 and by flow cytometry for the cell surface markers CD117 and CD184. Subsequent hepatic differentiation of the expanded endodermal cells was performed and early hepatic specification markers (hHEX, GATA4, AFP) as well as late hepatic markers (HNF4, Albumin, CYP1A1) were analysed by qRT-PCR. The number of hepatic precursors during expansion and differentiation was estimated using a lentiviral reporter construct expressing eGFP under control of the TTR promoter. Finally, metabolic functions such as urea production, CYP450 metabolism, and albumin secretion was analysed in these eGFP positive cells.
In conclusion, our modified protocol allowed the differentiation of human ESCs and iPSCs into proliferative endodermal progenitor cells. After sorting these cells, further propagation for several passages resulted in a maintained expression of endodermal marker genes and in a decrease of pluripotency-associated gene expression. The expanded cells can finally differentiate into hepatic cells, which we characterised by qRT-PCR and functional metabolic analyses. Further experiments need to reveal if the cells differentiated under these conditions were suitable for cell transplantation approaches *in vivo*.

T-1094

EPIGENETIC DYNAMICS OF JMJC-DOMAIN-CONTAINING DEMETHYLASES DURING THE DIFFERENTIATION OF HUMAN EMBRYONIC STEM CELLS TOWARDS HEPATOCYTES

Tia Hackett, Benjamin Tschudy-Seney, Xiaocui Ma, Manny Garcha, Ahmad Hasan, **Yuyou Duan**
Internal Medicine, University of California Davis Medical Center, Sacramento, CA, United States

Histone methylation and demethylation play important roles in regulating gene expression, genome integrity, and epigenetic inheritance, which regulate cell fate and identity. Histone demethylation is performed by histone demethylases which contain petidylarginine deiminase, lysine specific demethylase (LDS, containing LSD1 and LSD2), and at least 30 members of the JmjC-domain-containing (JmjC) demethylases. In this study, we investigated the dynamic changes of JmjC demethylases, identified their specific histone targets and evaluated potential biological function during the differentiation of human embryonic stem cells (hESC) towards hepatocytes. hESC line H9 was induced to definitive endoderm (DE), then hepatic differentiation was initiated using our established differentiation protocol. The differentiated cells were harvested at days 2, 5, 8, 15, 22, 30, and 36; cDNAs were then generated, and cellular total proteins, nuclear proteins and histone proteins were extracted at all these time points. In addition, the supernatants were collected every other day from day 10. 30 pairs of primers were designed and synthesized to amplify the 30 members of the JmjC demethylase family. All primer optimizations were done using Hela cells, human hepatoma cells, and human primary hepatocytes. qPCR results showed that expression of most JmjC demethylase family members decreased during the differentiation process when compared to those at day 2 after differentiation. Only five JmjC demethylase member genes were highly expressed at different time points; they were Hairless at day 15, JHDM1D, JMJD2A and JARID1A at day 22, and MINA53 at day 30, and their proteins were detected by Western blots. Some of the specific histone targets, such as JHDM1D targets, H3K9me2 and H3K27me; JMJD2A target, H3K36me2; and JARID1A target, H3K4me2, were identified by Western blots. However, histone targets of Hairless and MINA53 were not found. Histone modification of H3K4 and H3K36 activates genes, and of H3K9 and H3K27 silences genes. Therefore, histone demethylations on H3K4me2 and H3K36me2 would appear to activate gene expression, and on H3K9me2 and H3K27me2 to silences gene expression during the process of the differentiation and maturation. Our results from both qPCR and ELISA showed that the expression of alpha fetoprotein (AFP, immature marker) was highest at day 14, and its expression continued to decrease to day 36. Albumin

(ALB, more mature marker) expression kept increasing to day 30 of differentiation. This indicated that the cells were somewhat differentiated during the first two weeks, then the differentiated cells developed a more mature phenotype by late time points. Based on the time-course of the differentiation, it appears that Hairless was potentially associated with hepatic differentiation, JHDM1D, KMJD2A and JARID1A were associated with early maturation, and MINA53 was associated with late maturation. Further investigations will be performed to determine how these five demethylases may regulate hepatic differentiation and how they are regulated during hepatic differentiation. Thus, these results potentially represent an initial step in revealing the mechanism involved in the regulation of hESC differentiation towards hepatocytes.

M-CELLS REQUIRE SPI-B AND ARE INDUCED BY RANKL IN CULTURED ORGANOIDS

Kerstin Schneeberger[1], Michal Mokry[1], Wim de Lau[2], Hans Clevers[2], Edward Nieuwenhuis[1], **Sabine Middendorp**[1]
[1]Pediatrics, University Medical Center Utrecht, Utrecht, Netherlands, [2]Hubrecht Institute, Utrecht, Netherlands

Microfold cells (M-cells) are specialized intestinal epithelial cells in the follicle-associated epithelium overlying the Peyer's Patches. M-cells deliver luminal antigens to immune cells and thereby form a necessary link between the gut lumen and the mucosal immune system. In vivo studies have shown that M-cell differentiation can be induced upon binding of Rank ligand (RankL) to its receptor Rank.
We have used an intestinal organoid culture system to further investigate M-cell differentiation. We show that upon incubation with RankL, small intestinal organoids differentiated into Annexin V and GP2 expressing M-cells. These cells were able to take up beads, confirming M-cell function. Furthermore, we show that RankL-induced M-cell development was dependent on the transcription factor SpiB. Organoids established from SpiB-deficient mice did not develop into functional M-cells upon incubation with RankL despite expression of Rank. These data show that Rank-RankL interaction results in upregulation of SpiB, which is crucial for M-cell development.
However, forced overexpression of SpiB in intestinal organoids did not induce M-cell development, suggesting that SpiB is not operating autonomously. Therefore, we are currently looking into the involvement of another transcription factor in the induction of the M-cell developmental program.

MTOR MAINTAINS LGR5+ INTESTINAL STEM CELLS AND REGULATES SECRETORY INTESTINAL EPITHELIAL CELL DIFFERENTIATION THROUGH A WNT-INDEPENDENT MECHANISM

Leesa L. Sampson, Matthew Grogg, Yi Zheng
Experimental Hematology and Cancer Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States

The highly conserved Target of Rapamycin (TOR) signaling pathway links external stimuli, such as growth factors, amino acids, and energy status, to cell growth and proliferation machinery, allowing cells to properly respond to fluctuating physiological demands. mTOR is vital for embryogenesis and in lower organisms, such as *Planaria* and *Drosophila*, intrinsically regulates the adult stem cell proliferative response to injury and diet. How mammalian stem cells sense and respond to external stimuli via the mTOR pathway is not completely clear; but recent studies in murine hematopoietic stem cells (HSCs) suggest that mTOR signaling regulates stem cell self-renewal. Elevated mTOR activity is frequently associated with various types of cancer, including intestinal adenomas, leading to the therapeutic use of mTOR inhibitors that inhibit tumor cell proliferation and metastasis, but rarely lead to remission. It has been demonstrated that the likelihood of colon cancer relapse positively correlates with increased *Lgr5*-positive crypt base columnar (CBC) ISC marker expression, a relatively well-characterized, rapidly-dividing ISC population that is responsible for replacing shed gut intestinal epithelial cells (IECs). Understanding how mTOR functions in the ISC population could provide insights into the physiology of intestine biology and mTOR targeting therapy. A

recent study from the Sabatini lab found p-S6, a downstream mTOR target, absent from the *Lgr5*-positive ISC population. While we have also observed this phenotype, we find that mTOR itself and its direct target p-4E-BP1 does not exhibit a restricted expression pattern. As such, it is possible that mTOR has an ISC intrinsic role in regulating self-renewal and differentiation.

Here we present the first *mTOR* ISC and IEC progenitor conditional deletion mouse model ($mTOR^{lox/lox}$ *villin-cre* or $mTOR^{\Delta IEC}$ for intestinal epithelial cell deletion) designed to investigate the intrinsic requirements for mTOR in ISCs and their progeny. We find that mTOR is surprisingly dispensable for murine intestinal development and organismal survival. While ≈5-15% smaller in body size and weight than wild-type mice, $mTOR^{\Delta IEC}$ mice are fertile and survive at the WT rate. Histology shows that $mTOR^{\Delta IEC}$ proximal small intestinal villi are lengthened, but ileal villi are shortened, correlating with regional differences in $mTOR^{\Delta IEC}$ crypt cell proliferation rates and villus tip-localized IEC apoptosis. While ISC-associated marker gene expression, including Lgr5, Ascl2 and Olfm4, are significantly reduced in the mutant, Wnt signaling activity, a major ISC-regulatory pathway, remains unaffected. An examination of the secretory IEC differentiation status reveals that $mTOR^{\Delta IEC}$ goblet cells remain present, but are smaller and stain comparatively weakly with Mucin2, indicating reduced mucus production. $mTOR^{\Delta IEC}$ Paneth cells, however, are drastically reduced both in size and number, while enteroendocrine cells exhibit a four-fold increase. *In vitro* studies reveal that isolated $mTOR^{\Delta IEC}$ crypts fail to form enteroids in culture but can be rescued by exogenous Wnt3a, further indicating that mTOR is dispensable for Wnt signaling. Overall our data indicate that mTOR intrinsically regulates Lgr5-positive ISCs and their differentiation program, but is not essential for intestinal epithelial homeostasis and function.

SOX4 REGULATES PROLIFERATION IN THE MURINE INTESTINAL STEM CELL COMPARTMENT

Adam D. Gracz[1], Danny C. Trotier[2], Scott T. Magness[3]

[A]Cell Biology and Physiology, [B]Medicine, [C]Medicine and Cell Biology and Physiology, [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Intestinal epithelial stem cells (IESCs) must balance proliferation and differentiation in order to maintain a rapid rate of physiological renewal. Sox factors are versatile regulators of cell fate and proliferation in a wide range of tissues, and are expressed in stem and progenitor cells of the intestinal epithelium. Here we utilize a conditional knockout mouse model to demonstrate that intestinal epithelial-specific loss of Sox4 leads to an upregulation of IESC biomarkers, as well as an increase in markers of proliferation and downstream targets of the Wnt pathway. Interestingly, while Sox4 knockout animals exhibit no hyperplastic phenotype in vivo, intestinal crypts isolated from Sox4-null epithelium exhibit enhanced growth in vitro, consistent with constitutively active Wnt signaling. Together, these results suggest that Sox4 is a negative regulator of Wnt signaling in vivo, and may act to mediate growth signaling between epithelial cells that can be compensated for by epithelial-mesenchymal crosstalk.

MATURATION OF MAMMALIAN INTESTINAL EPITHELIAL PROGENITORS, IN VITRO AND IN VIVO

Robert P. Fordham[1], Shiro Yui[3], Alison Madgwick[1], Tetsuya Nakamura[3], Nicholas RF Hannan[2], Ludovic Vallier[2], Roger A. Pedersen[2], Mamoru Watanabe[3], Kim B. Jensen[4]

[A]Wellcome Trust/Medical Research Council Stem Cell Institute, [B]Anne McLaren Laboratory for Regenerative Medicine, [1]University of Cambridge, Cambridge, United Kingdom, [2]Department of Gastroenterology and Hepatology, Tokyo Medical and Dental University, Tokyo, Japan, [3]Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark

The principle objective of this study was to define the maturation of intestinal epithelium from its foetal state, using three-dimensional in vitro cultures and orthotopic transplantation.
The mature intestinal epithelium is the most rapidly self-renewing tissue in adult mammals, consisting of differentiated villi and proliferative crypt compartments, where Intestinal Stem Cells (ISCs) reside. In mice at birth, the intestine is developmentally immature, lacking crypts and Paneth cells, the supportive cells of the adult ISC niche. The overall process of intestinal development is similar in humans, except that crypt formation occurs in late gestation. Therefore studying mouse intestinal development provides a model system to understand the events that occur in humans in utero.
Mature intestinal epithelium can be propagated from ISCs in vitro as three-dimensional 'organoids'. Here I describe the establishment and utilisation of long-term three-dimensional cultures from immature intestine, which exist as cystic epithelial spheroids, 'Foetal Enterospheres' (FEnS). FEnS represent a transient state in tissue maturation that can also be captured developmentally from human foetal tissue and pluripotent cells differentiated into posterior definitive endoderm.
FEnS are of primitive cellular composition, with distinct signalling requirements to adult organoids. Notably, they do not require exogenous stimulation of the Wnt pathway for their maintenance and do not contain secretory cells, including Paneth cells. However, treatment of foetal intestinal epithelium with Wnt3a and R-Spondin (a potentiator of Wnt signalling) is sufficient to induce in vitro maturation to adult-like organoids. These organoids contain Paneth cells and can subsequently be maintained without exogenous Wnt3a, indicative of complete functional maturation. Furthermore this data suggests that an increase in Wnt signalling in intestinal epithelial cells during postnatal development may drive tissue maturation in vivo.
In a complementary approach to assess the in vivo potential of immature intestinal epithelium, FEnS were transplanted into a mouse model of ulcerative colitis previously used to demonstrate the contribution of adult colonic organoids to crypt regeneration. Foetal-derived cells were able to adhere to the denuded lamina propria within three hours after transplantation and engraft into the regenerating colonic tissue by three days. By one week after transplantation, the foetal cells formed adult crypt-like structures, morphologically indistinguishable from host crypts and with evidence of goblet cell differentiation. These FEnS-derived crypts were maintained for over one month, with localisation of proliferative cells to the nascent crypt base and expression of colonic epithelial markers. Altogether, FEnS demonstrated an ability to engraft into the injured adult colon and contribute to de novo cryptogenesis during colonic epithelial regeneration. These findings have implications for the choice of transplantable cell type in regenerative therapies, suggesting that easily-expandable immature progenitors have the potential to mature in vivo and contribute to tissue repair.

T-1105

THE PLURIPOTENCY FACTOR LIN28 REGULATES STEM CELL HOMEOSTASIS, TISSUE REGENERATION AND TUMORIGENESIS IN MAMMALIAN INTESTINES

Ho-Chou Tu
Hematology/Oncology, Children's Hospital Boston, Boston, MA, United States

LIN28A and LIN28B are RNA-binding protein paralogs highly expressed in embryonic stem cells and in early developing tissues. Through blocking the terminal processing of let-7 miRNAs and regulating the translation of a number of mRNA binding targets, LIN28 controls an array of targets that mediate proliferation, pluripotency, differentiation and metabolism in embryonic stem cells. To explore the role of the Lin28/let-7 axis in adult tissues and how the perturbation of its function might lead to diseases, we generated an inducible Lin28a (iLin28a) transgenic animal, so that Lin28 can be overexpressed once treated with doxycycline. Strikingly, upon Lin28a induction, we observed a dramatic disruption of the epithelial structure in the small intestines and colon. This disruption is evidenced by a near-complete loss of terminally differentiated cells and aberrant enlargement of the proliferative crypts. Interestingly, the Lgr5-positive intestinal stem cells (ISC) are not affected by iLin28a, suggesting that the targeted population of Lin28a-induced crypt expansion may be the transit amplifying progenitor cells instead of the stem cells. Furthermore, we found that iLin28a animals are more susceptible to IR-induced intestinal damage. Supporting this finding, overexpression of let-7 miRNA protected animals from irradiation-induced Gastrointestinal Syndrome.

These results indicate a critical role of the let-7 miRNAs to maintain intestinal homeostasis, as well as injury repair and tissue regeneration. Indeed, the let-7 miRNAs are highly expressed both in the crypts and the villi, while a number of let-7 miRNAs are downregulated upon IR injury. Lastly, both LIN28A and LIN28B are highly expressed in a variety of human cancers. The molecular mechanisms by which Lin28a/b promote tumorigenesis can be partly explained by the indirect upregulation of let-7 targets, which include oncogenes such as cMyc, RAS, HMGA2 and Cyclin D1. To model the role of the Lin28/let-7 axis in tumorigenesis in vivo, we overexpressed Lin28a and LIN28B specifically in the intestinal epithelia and found that these animals developed aggressive intestinal adenocarcinoma. In summary, we propose the Lin28/let-7 axis as important players regulating both injury-induced tissue regeneration, as well as tumorigenesis. Exploration of specific molecules targeting this pathway will provide novel insights into potential therapeutics for cancer and regenerative medicine.

T-1106

MODULATION OF COLONIC STEM CELL MICRORNA EXPRESSION BY A CHEMOPROTECTIVE DIET

Manasvi S. Shah[1], Laurie A. Davidson[2], Eunjoo Kim[3], Jason M. Knight[4], Roger S. Zoh[5], Jennifer S. Goldsby[2], Evelyn S. Callaway[2], Ivan Ivanov[6], Robert S. Chapkin[2]

[1]Endocrinology, Boston Children's Hospital, Boston, MA, United States, [A]Program in Integrative Nutrition & Complex Diseases, [B]Departments of Cellular and Molecular Medicine, [C]Electrical Engineering, [D]Statistics, [E]Veterinary Physiology & Pharmacology, [2]Texas A& M University, College Station, TX, United States

Perturbations in adult stem cell dynamics are generally believed to represent an early step in colon tumorigenesis. Recently, several studies have demonstrated the role of miRNAs in the maintenance of colon cancer stem cells. However, to date, the effects of chemoprotective dietary components (omega-3 fatty acids and butyrate) on colonic stem cell non-coding miRNA signatures have not been determined, nor has the miRNA expression profile in colon stem cells been documented. Therefore, our overall goal was to better understand how a colonic stem cell population responds to environmental factors such as diet and carcinogen. With the identification of Lgr5 as a definitive marker for intestinal stem cells, we used the highly novel, recently described, Lgr5-EGFP-IRES-cre ERT2 knock in mouse model. The mice were injected with azoxymethane (AOM, a colon carcinogen) or saline (control) and fed a chemoprotective diet containing omega-3 fatty acids and fermentable fiber (fish oil + pectin) or a control diet (corn oil + cellulose). Single cells were isolated from the colonic crypt and three different populations of cells were collected via fluorescence activated cell sorting (FACS): Lgr5high (stem cells), Lgr5low (daughter cells) and Lgr5negative (differentiated cells). Expression of 384 mature rodent miRNAs was determined from total RNA isolated from the sorted cells, and 29 miRNAs in stem cells were significantly altered ($P < 0.05$) compared to differentiated cells. Specifically, three miRNAs, miR-125a-5p, miR-190 and miR-191, exhibited significantly ($P < 0.05$) higher levels in stem cells compared to daughter cells and differentiated cells. Notably, the “oncomiR” miR-21 was significantly upregulated in the corn oil + cellulose + AOM group (CCA) compared to fish oil + pectin + AOM group (FPA) in stem cells, but not in daughter or differentiated cells. Also, in stem cells, miR-19b, miR-26b, miR-27b and miR-203 were upregulated by CCA compared to FPA. However, in differentiated cells, miR-19b and miR-18a were significantly downregulated ($P < 0.05$) in CCA fed mice. These data indicate for the first time that select dietary cues can impact stem cell regulatory networks, in part, by modulating the steady-state levels of miRNAs. To our knowledge, this is the first study to utilize Lgr5+ reporter mice to determine the impact of diet and carcinogen on miRNA expression in intestinal stem cells. Supported by NIH CA168312, CA129444.

A CENTRAL ROLE FOR STROMAL WNTS IN INTESTINAL STEM CELL SELF-RENEWAL

Zahra Kabiri[1], Gediminas Greicius[2], Steffen Biechele[3], Babita Madan[1], Alex Zhong[4], Hamed Zaribafzadeh[1], Edison Edison[1], Ralph M. Bunte[1], Bart O. Williams[4], Janet Rossant[3], David M. Virshup[1]

[1]Cancer and Stem Cell Biology, Duke-NUS Graduate Medical School, Singapore, Singapore, [2]National Cancer Center of Singapore, Singapore, Singapore, [3]Program in Developmental and Stem Cell Biology, The Hospital for Sick Children Research Institute, Toronto, ON, Canada, [4]Center for Skeletal Disease Research, Van Andel Research Institute, Grand Rapids, MI, United States

Aberrant Wnt/β-catenin pathway activity is associated with many diseases. Inhibition of the Wnt pathway has therapeutic promise but may adversely impact the self-renewal of stem cells in different adult tissues. Furthermore, it is hard to predict toxicity as Wnt-producing cells in normal and transformed tissues are poorly defined.
We used genetic and pharmacological approaches to inhibit Wnt secretion to assess the effect on the mouse small intestine, a tissue thought to be highly Wnt dependent. First, we generated mice with a targeted deletion of Porcn, a non-redundant membrane bound O-acyltransferase enzyme essential for all Wnt secretion, in gut epithelial cells. Surprisingly, while epithelial Wnts are believed to play crucial roles in the small intestine homeostasis, Wnt target gene expression, proliferation and differentiation was normal in the intact gut of the villin-Cre/Porcnflox mice. Confirming the essential role of Porcn, we found that Porcn-deleted epithelial cells, unlike wildtype cells, cannot form organoids ex vivo unless supplemented with either stromal cells or exogenous Wnts. Thus, epithelial Wnt secretion can compensate for the loss of stromal Wnts in ex vivo growth, but the epithelial Wnts are dispensable in the intact intestine.
We next investigated whether pharmacological Porcn inhibition, which targets both epithelial and stromal, affected epithelial cell proliferation in vivo. Indeed, mice treated with the Porcn inhibitor C59 had a dose-dependent decrease in the expression of Wnt/β-catenin target genes, and in intestinal proliferation, leading to markedly impaired small intestine homeostasis. Thus, global Wnt secretion is required for intestinal proliferation.
Taken together, the data confirm the central role of Wnt secretion in intestinal homeostasis, and suggest that the stromal layer has a major role producing these Wnts.

HIGHLY EFFICIENT LUNG PROGENITOR GENERATION FROM HUMAN iPSC BY SELECTIVE CHEMICAL SCREENING

Hongmei Mou[1], Anthony Arvanites[2], Lance Davidow[2], Kevin Lam[2], Karen Kotkow[2], Lee Rubin[2], Jayaraj Rajagopal[1]
[1]Center for Regenerative Medicine, Massachusetts General Hospital, Boston, MA, United States, [2]Department of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, United States

We have recently published a step-wise method for the generation from human iPSC of NKX2.1+ multipotent lung progenitor cells without contamination with NKX2.1+ brain and thyroid progenitors. Such lung multipotent progenitors can be converted into NKX2.1+SOX2+ proximal airway progenitors and further into NKX2.1+p63+ airway basal stem cells (Mou et al., 2012) that are both progenitor populations for mature airway epithelium. However, the major obstacle preventing the actual development of human lung disease models using iPSC is the inability to produce with near purity lung progenitors and then subsequently into differentiated pulmonary epithelial cell types in vitro. In this work, we have optimized our differentiation protocol to produce human airway progenitors with high efficiency from human iPSCs by using unbiased chemical screens. We have identified 6 molecules from the Kinase Compound Set and 6 drugs from NIH Clinical Collection which produced statistically significant (more than 3 fold) increases in the percentage of NKX2.1+ lung progenitor cells. We found out that multiple compound hits target PI3K/mTOR, PKC and MEK1/2-related signaling pathways, suggesting that these biological pathways are actively involved in human lung organogenesis. By performing additive/synergistic experiments using our lead hits, we generate a robust, economically efficient and generally applicable protocol for a highly enriched population (up to 85% purity) of lung progenitors. The derived lung progenitors possess the characteristic lung markers and lack of neural and thyroid markers. Importantly, the lung progenitors can be matured into airway basal stem cells (NKX2.1+p63+) and further differentiated into physiologically active ciliated cells in vitro.

Our success of generation of functional airway progenitor cells with near purity is an important step closer to the utility of disease-specific iPS cells to model airway diseases like cystic fibrosis, asthma, bronchiectasis and lung cancer.

T-1112

HUMAN LUNG STEM CELLS AND THEIR POTENTIAL.

Feride Oeztuerk-Winder[1], Nicholas Bonenfant[2], Edgar J. Ruiz[1], Daniel J. Weiss[2], Juan-Jose Ventura[1]

[1]Wellcome Trust - Medical Research Council Cambridge Stem Cell Institute, Cambridge, United Kingdom, [2]University of Vermont College of Medicine, Burlington, VT, United States

Lung disease is the third most common cause of death in the United States and Europe. In many cases lung transplantation is the only definitive treatment, yet only 2700 lung transplants are performed each year, limited primarily by a lack of donor organs. The development of engineered lung tissue, which could be created using a patient's own cells, could have a significant impact on the treatment of end-stage lung disease.
We have isolated adult human lung stem cells (HLSCs), based on Lgr6/E-Cadherin expression, which culture indefinitely and can be considered as stem/progenitor precursors of alveolar epithelium (Oeztuerk-Winder *et al*., 2012). Optimized protocols enable *in vitro* differentiation and transformation of HLSCs, observing a matrix-directed lung cell specification in a variety of substrates (Matrigel, Fibronectin and Laminin). *In vivo* assays to investigate the cellular differentiation and self-renewal potential of HLSCs under physiological conditions included murine kidney capsule implants, which provide conditions that promote tissue differentiation.
We have shown that implanted HLSCs differentiate into various lung cell types *in vivo* and exhibit the same morphology as the lung, whilst also expressing lung tissue specific markers. The contribution of HLSCs to the repair of both human lung explants *in vitro* and murine lung tissue *in vivo* was also shown following bleomycin-induced injury. Cytokine and growth factor release, that are central to tissue remodelling, has also been demonstrated (Ruiz *et al*., submitted).
In order to engineer an artificial airway both a scaffold and stem/progenitor cells are required. The scaffold must provide the correct conditions for cell adhesion, proliferation and differentiation, as well as the transport of nutritional and growth factors. Decellularized lungs provide an opportunity to retain several key characteristics of the normal lung matrix and are superior to other matrix options for lung tissue engineering. We seeded Lgr6/E-Cadherin positive HLSCs into decellularized mouse or human lungs. They were then recellularized and differentiated into a alveolar type I and ATII epithelial cells in the lung.
In our work, we demonstrate initial progress towards the development of functional engineered lung tissue using rodent or human decellularized models. Besides the potential use in a clinical setting, engineered lung tissue can be used in the laboratory to study a wide variety of important aspects of lung biology and physiology.

BACKGROUND: Two populations of Nkx2.1+ progenitors in the developing foregut give rise to the entire post-natal lung and thyroid epithelium. We demonstrated the directed differentiation and purification of primordial lung and thyroid progenitors derived from mouse embryonic stem cells (ESCs) by recapitulating normal early endoderm and lung development in vitro. A fundamental limitation in the field of lung regeneration is the lack of a platform to

assess the functional capacity of putative stem/progenitor cells. We sought to test the feasibility of using a recently described decellularized murine lung as a platform to assess repopulation potential and differentiation repertoire of ESC-derived stem/progenitor cells ex-vivo.

METHODS AND RESULTS: We developed a faithful lung epithelial reporter line with GFP targeted to the Nkx2.1 locus of mouse embryonic stem cells (ESCs) by homologous recombination. These ESCs were differentiated efficiently to anterior foregut endoderm using Activin-A followed by brief inhibition of BMP and TGF-beta. Key candidate growth factors suggested to specify lung lineages (e.g. FGF2, BMP4 and Wnt3a) led to efficient induction of Nkx2.1 by day 9 and on day 15 these Nkx2.1GFP+ were sorted to purity. With further expansion these purified cells expressed a global transcriptome that overlaps with developing lung and thyroid epithelium. To test the functional capacity of these putative lung progenitors, purified Nkx2.1 GFP+ cells were mixed with low melting temperature agarose and delivered by intra-tracheal instillation into decellularized murine lungs. The lungs were subsequently cooled and sectioned into 2-3mm thick slices and each slice was cultured in media containing Fgf2 and Fgf10 for seven days to promote expansion and further maturation of specified lung progenitors. The media was then changed to a fetal lung maturation media, supplemented with dexamethasone and cyclic AMP to augment the expression of lung epithelial genes, including surfactant protein C (Sftpc). Histology of these lung sections revealed that Nkx2.1 GFP+ cells were able to seed alveolar lung regions and adopt the morphology of lung alveolar epithelia. Approximately 70% of engrafted cells retained Nkx2.1 expression. Some engrafted cells acquired a flattened morphology, lost expression of Nkx2-1 protein and exhibited membrane associated expression of T1alpha, a pattern reminiscent of developing type I alveolar epithelial cells (AEC1). qRT-PCR of recellularized lung confirmed upregulation of additional markers of the developing lung including Sftpc, Sftpb and Scgb1a1 (CCSP). When sorted Nkx2.1GFPneg cells were seeded in an identical manner, there was virtually no engraftment observed. Control undifferentiated ESCs exhibited chaotic, clumped recellularization without significant expression of lung epithelial markers.

CONCLUSIONS

Purified mouse ES-derived Nkx2.1 GFP+ cells reconstitute a distal or alveolar phenotype when seeded in a 3-D decellularized murine lung scaffold.

CD24 MARKS METASTATIC LUNG TUMOR-PROPAGATING CELLS WITH ACTIVE HIPPO SIGNALING

Allison N. Lau[1], Stephen J. Curtis[1], Samuel P. Rowbotham[1], Christine Fillmore[1], Morvarid Mohseni[1], Kerstin W. Sinkevicius[1], Zandra E. Walton[2], Juliana Barrios[1], Alexander Beede[1], Fernando D. Camargo[1], Kwok-Kin Wong[2], Carla F. Kim[1]
[1]Stem Cell Program, Boston Children's Hospital, Boston, MA, United States, [2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Tumor-propagating cells (TPCs) contribute to cancer progression and metastasis. Our earlier studies found that the marker Sca-1 enriched for TPCs in murine lung tumors driven by oncogenic Kras and p53 loss. Here, we used this mouse model of lung cancer to probe the connection between tumor-propagating ability and metastatic capacity. To identify cell surface markers and further characterize TPCs, we conducted microarray analysis of Sca-1+ and Sca-1- tumor cells and found the marker CD24 was upregulated 3-fold (p=0.0057) in Sca-1+ cells. CD24 has been implicated in cancer progression, yet its role in metastatic lung cancer is lacking. Selection of CD24-expressing cells from primary murine lung tumors enriched for tumor-propagating activity and metastatic capacity in orthotopic transplantations. All recipient mice developed at least one lung tumor after transplantation of 10,000 CD24+ (13/13) or CD24- cells (14/14). 50% of recipients of 1,000 CD24+ cells developed tumors (3/6), whereas recipients of 1,000 CD24- cells did not exhibit lesions (0/3). The average number of tumors (14±6 vs 4.8±4.2, p=0.0019) and the average percentage of lung area filled with tumor (58%±23 vs 19%±20%, p=0.0017) were significantly greater in recipients of CD24+ vs. CD24- cells. Strikingly, there was an increase in metastases in recipients of CD24+ (11/12) vs. CD24- cells (6/12, p =0.03). CD24+ recipients developed metastatic lesions in the chest wall (11/11), local lymph nodes (4/11), and distant sites (4/11). CD24- recipients also had small metastases in the chest cavity (6/6) yet had limited development of local lymph node metastases (1/6) and no distant metastases (0/6). This demonstrated that CD24 prospectively marked metastatic tumor cells. In lung cancer cell lines, knockdown of CD24 decreased migration and reduced metastases post-transplantation. In transwell migration assays, shCD24 lines showed a 3-4-fold reduction in migration compared to shGFP cells (p<0.03). To assess metastatic capacity in vivo, shGFP and shCD24 cells were injected into the tail vein of nude mice. Transplantation of the shCD24 lines resulted in significantly fewer numbers of lung metastases after tail vein injection (p = 0.002). These findings strongly suggest that CD24 plays a functional role in TPC activity and metastasis. In an effort to evaluate other genetic programs that could participate in metastasis, we performed gene set enrichment analysis on the Kras;p53 TPC gene expression data. Two upstream regulators of the Hippo signaling pathway, Nf2 and Lats1, were part of the core enrichment in many of the top gene sets. Knockdown of the Hippo pathway mediators Yap and Taz decreased migration of murine lung cancer cell lines, (3.8-10-fold compared to shGFP, p<0.05) supporting a role for this pathway in lung cancer progression. These Yap/Taz knockdown cell lines were injected via tail vein to assess metastatic capacity in vivo. Metastases were less frequent in recipients of shTaz cells compared to shGFP (p<0.05). Our data suggest a novel role for CD24 and the Hippo pathway in regulating tumor-propagating cells and metastasis. Our characterization of aggressive TPCs within lung tumors has defined a subset of cells involved in metastatic lung cancer and the interruption of CD24 and Hippo signaling pathways may lead to new therapeutics for metastasis.

RUNX1 AND P21 SYNERGISTICALLY LIMIT THE EXTENT OF HAIR FOLLICLE STEM CELL QUIESCENCE IN VIVO

Jayhun Lee[1], Charelene S.L. Hoi[2], Karin C. Lilja[3], Brian S. White[4], Song Eun Lee[1], David Shalloway[1], Tudorita Tumbar[1]
[1]Molecular Biology & Genetics, Cornell University, Ithaca, NY, United States, [2]Ben May Department of Cancer Research, University of Chicago, Chicago, IL, United States, [3]Sackler Institute of Graduate Biomedical Sciences, New York University, New York, NY, United States, [4]Department of Internal Medicine, Washington University, St. Louis, MO, United States

Mechanisms of tissue stem cell (SC) quiescence control are important for normal homeostasis and for preventing cancer. Cyclin-Dependent Kinase inhibitors (CDKis) are known inhibitors of cell cycle progression. We document CDKis expression in vivo during hair follicle stem cells (HFSCs) homeostasis and find p21, p57 and p15 up-regulated at quiescence onset. P21 appears important for HFSC timely onset of quiescence. Conversely, we find that Runx1, which is known for promoting HFSC proliferation, represses p21, p27, p57 and p15 transcription in HFSC in vivo. Intriguingly, in cell culture, tumors, and normal homeostasis Runx1 and p21 interplay modulates proliferation in opposing directions under the different conditions. Unexpec-

tedly, Runx1 and p21 synergistically limit the extent of HFSC quiescence in vivo, which antagonizes the role of p21 as a cell cycle inhibitor. Importantly, we find in cultured keratinocytes that Runx1 and p21 bind to the p15 promoter and synergistically repress p15 mRNA transcription, thereby restraining cell cycle arrest. This documents a surprising ability of a CDKi (p21) to act as a direct transcriptional repressor of another CDKi (p15). We unveil a robust in vivo mechanism that enforces quiescence of HFSCs, and a context-dependent role of a CDKi (p21) to limit quiescence of SCs, potentially by directly down-regulating mRNA levels of (an)other CDKi(s).

IDENTIFICATION OF NOVEL MECHANISMS INVOLVED IN STEM CELL ACTIVATION IN THE SKIN

Jill M. Goldstein, Andrew Chun, Valerie Horsley
Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT, United States

The cellular and molecular mechanisms that regulate hair follicle stem cell activity are not fully understood. We have previously identified that the calcineurin/NFAT pathway controls follicular stem cell activity and inhibition of this pathway can promote hair growth. To identify novel molecular mechanisms that regulate stem cell activity in the hair follicle, we have defined a unique molecular program that is altered in hair follicle stem cells using pharmacological inhibition of calcineurin signaling with cyclosporine A (CSA). This program is distinct from the gene signature of activated stem cells in the hair follicle germ and that induced by CSA treatment in basal keratinocytes of the interfollicular epidermis, suggesting that calcineurin signaling regulates distinct genes in hair follicle stem cells. Specifically, our results identify prolactin receptor (PRLR) as a calcineurin/NFATc1 target gene in follicular stem cells. Inhibition of calcineurin with CSA or genetic ablation of NFATc1 in the skin of mice (NFATc1 cKO) results in the loss of prolactin receptor mRNA and protein expression in hair follicle stem cells. Furthermore, we demonstrate that NFATc1 cKO mice display precocious hair growth during pregnancy, when systemic levels of prolactin are elevated and maintain follicles in a resting state. These findings uncover an NFATc1-PRLR axis that controls stem cell activity in the skin and may reveal the molecular events that contribute to human hair loss associated with pregnancy during the scalp disorder telogen effluvium.

NEW INTRINSIC LAYER OF STEM CELLS HOMEOSTASIS REGULATION REVEALED BY COMPETITIVE BALANCE OF INTRABULGE BMP/WNT SIGNALING DURING HAIR CYCLIC ACTIVATION

Eve Kandyba[1], Yvonne Leung[1], Yi-Bu Chen[2], Randall Widelitz[3], Cheng-Ming Chuong[3], **Krzysztof Kobielak**[1]
[A]The Broad CIRM Center for Regenerative Medicine and Stem Cell Research, Department of Pathology, [B]Norris Medical Library, [C]Department of Pathology, [1]University of Southern California, Los Angeles, CA, United States

Hair follicles facilitate the study of stem cells (SCs) behavior because SCs in progressive activation stages are ordered within the follicle architecture and they are capable of cyclic regeneration. We revealed how the underlying molecular mechanisms of Bone morphogenetic protein (BMP) signaling governs the homeostasis of hair follicle stem cells (hfSCs) in vivo. In our recently published model we demonstrated that BMP-inactivated hfSCs exhibit molecular profiles resembling those of hair germs, but still retain multipotentiality after transplantation in vivo. In addition, BMP-inhibited hfSCs display altered BMP and Wnt pathways, exhibiting up-regulation of Wnt7a, Wnt7b ligands and only one Wnt receptor Frizzled (Fzd) 10. We demonstrated that Wnt7a works intrinsically to regulate ligand–receptor-dependent cross talk between BMP and Wnt signaling in hfSCs homeostasis. These results highlight a previously unknown intra-stem cell antagonistic competition, between BMP and Wnt signaling, to balance stem cell activity. We developed this story further and demonstrated the role of Wnt7b in hair follicle Stem Cells regulation, hair morphogenesis and postnatal cycling. Moreover, we also built upon the significance of downstream effectors of canonical BMP signaling, Smads 1/5/8 during hair morphogenesis and postnatal hfSC homeostasis. Collectively, these findings support our discoveries and the existence of one more hierarchical layer regulating stem cell homeostasis in addition to the stem cell–dermal papilla and the hair follicle–adipocyte interaction layers.

GENERATION OF FOLLICULOGENIC HUMAN EPITHELIAL STEM CELLS FROM INDUCED PLURIPOTENT STEM CELLS

Ruifeng Yang[1], Ying Zheng[2], George Cotsarelis[2], Xiaowei Xu[1]
[A]Department of lab med and pathology, [B]Department of dermatology, [1]University of Pennsylvania, Philadelphia, PA, United States

Directed differentiation of pluripotent stem cells into a variety of cell types opens new possibilities for regenerative medicine. Epithelial stem cells (EpSCs) in the hair follicle bulge are required for hair follicle growth and cycling, while also contributing to wound healing. Human EpSCs (hEpSCs) in the hair follicle express CD200, ITGA6 and cytokeratin-15 (KRT15) but their isolation and propagation for tissue engineering purposes remains a challenge. Generating sufficient numbers of EpSCs is crucial for treatment of hair loss and other degenerative skin diseases. Here we develop a strategy to differentiate human induced pluripotent stem cells (hiPSCs) into CD200+/ITGA6+ EpSCs that can reconstitute the epithelial components of hair follicles and interfollicular epidermis. CD200+/ITGA6+ EpSCs emerged at day 11 and reached a maximum level around day 18 during the hiPSC differentiation. The hiPSC-derived CD200+/ITGA6+ cells have high colony forming efficiency and show a similar gene expression signature as that of EpSCs isolated directly from human hair follicles. In a skin reconstitution assay, hiPSC-derived CD200+/ITGA6+ cells combined with neonatal mouse dermal cells injected into an immunodeficient mouse produce all hair follicle lineages including hair shaft, inner and outer root sheaths. The regenerated hair follicles consist of a KRT15+ stem cell population and in situ hybridization confirms that the follicular epithelium and interfollicular epidermis are composed entirely of human keratinocytes. Our results indicate that hiPSC-derived CD200+/ITGA6+ cells are molecularly and functionally similar to human hair follicle-derived EpSCs. These results suggest that a sufficient number of folliculogenic human EpSCs can be generated from hiPSCs to develop treatments for hair loss, wounds and other degenerative skin disorders.

EPIDERMAL STEM CELL SPRAY FOR BURN WOUND HEALING

Roger Esteban-Vives[1], Matthew T. Young[1], Pattrick Over[1], Peter Rubin[2], Joerg Gerlach[1]
[A]Surgery, [B]Plastic Surgery, [1]Pittsburgh University, Pittsburgh, PA, United States

Introduction
The current treatment for burn wound healing is based mainly on auto-transplantation (Tx). Problems with healing include patient's donor skin area availability, sometimes scar formation, a loss of functionality, and poor aesthetic results. Because of donor area limitations, this method is often insufficient to heal large burn areas, especially larger third degree burn injuries.
Our group developed a therapy using autologous progenitor epidermal cell isolation addressing second degree burn wounds. Previous results from the team suggested that fresh isolated autologous adult dermal fibroblast and allogeneic fetal derived dermal fibroblast contains a MSC-like population. This MSC-like cell population in combination with fibroblast are of interest for regenerative cell-based therapy in full thickness burn healing.
Materials and Methods
Adult epidermal cells were isolated from adult skin biopsies obtained from patients. Adult and Fetal dermal cells were derived from plastic surgery and fetal tissue donations (after medically indicated abortions), respectively. Conceptual in vitro work on dermal cell isolation, cell culture, cell characterization (Flow cytometry and Gene expression), and cell spraying were performed as key proof of concept studies for full thickness therapy. Cell banking work included the development of clones and cryopreservation methods.
Results
Flow cytometry analysis revealed a heterogeneous differentiation stage keratinocyte population including a Stem Cell population (K15+/α6-integrin+) during epidermal cell isolation process. The results of autologous keratinocyte isolation allow us to treat patients in a therapy that is combined with cell spraying for second degree burn healing.

The fetal and adult dermal cell isolation procedure showed a fibroblast population with an additional BM-MSC population characterized by flow cytometry and gene expression. Fetal and adult dermal cells exhibiting also are capable of differentiating to chondrogenic, osteogenic and adipogenic cells using in-vitro assays.
In vitro cultured fetal dermal derived cells revealed BM-MSC-like cell characteristics allowing them as an off-the-shelf product for large burned patients.
Conclusions
As a result of our work, freshly isolated epidermal cells, in combination with spray-Tx, can enhance wound recovery skin regeneration.
Current cell-spray grafting therapy is limited to partial-thickness second degree burn wounds, however, promising preliminary results on dermal cell isolation and in vitro cultured fetal cells (as a cell-banking product), suggest that the therapy can be addressed to third degree burn wounds.

T-1127

CELLULAR AND SIGNALING MECHANISMS THAT REGULATE HAIR FOLLICLE STEM CELLS BY LIVE IMAGING

Valentina Greco
Yale Medical School, New Haven, CT, United States

Stem cells and their niches are critical for tissue development and regeneration. Yet, we still lack knowledge of the sequential steps stem cells undertake to sustain regeneration. Outstanding unanswered questions remain 1) what is the behavior of stem cells, 2) which signals control stem cell behaviors and 3) what is the functional role of the niche during physiological regeneration. A current challenge in the field is having access to a well-defined stem cell niche in which the orderly development of stem cells can be observed, characterized and manipulated in vivo.
My laboratory has recently established an in vivo strategy to visualize the components of the hair follicle stem cell niche, track them over time and manipulate them by two-photon microscopy in live mice. By these means, we have uncovered that hair follicle growth relies on both spatial organization of cell divisions as well as directional cell movements within the stem cell/progeny compartments. In order to address which cells and which behaviors within the stem cell/progeny compartments are controlled by hair follicle regenerative signaling pathways, we have utilized genetic approaches to stabilize the Wnt pathway in subset of cells in combination with our live imaging set-up. Our data suggest that Wnt can control specific stem cell/progeny behaviors depending on the position of these cells within their compartments. In order to dissect whether Wnt effect on specific subset of cells relies on the presence of the niche, we have set up a two-photon based specific cell ablation approach. By these means, we have been able to demonstrate that the niche is required for hair follicle tissue regeneration. We are currently applying these approaches to address whether the Wnt dependent cell behaviors we have identified depend on the presence of the niche.
Thus, we have established an in vivo approach that has led to the discovery of unpredicted cellular mechanisms of growth regulation, and enabled us to precisely investigate functional requirements of stem cell niche components along with key signaling pathways during the process of physiological regeneration.
Acknowledgment: this work is supported in part by NIH-NIAMS and ACS.

TCF3 PROMOTES CELL MIGRATION AND WOUND REPAIR THROUGH REGULATION OF LIPOCALIN2

Amy T. Ku[1], Qi Miao[2], Yudai Nishino[2], Jeffrey M. Howard[1], Gloria E. Garcia[2], Ajay S. Rao[2], Diep N. Le[2], Timothy M. Shaver[2], Hoang Nguyen[2]
[A]Interdepartmental program in Translational Biology and Molecular Medicine, [B]Stem Cells and Regenerative Medicine Center, [1]Baylor College of Medicine, Houston, TX, United States

Cell migration is an integral part of re-epithelialization during the skin wound healing, a complex process involving molecular controls that are still largely unknown. Here we identify a novel role for Tcf3, an essential transcription

factor regulating embryonic and adult skin stem cell functions, as a key downstream effector of epidermal wound repair. We show that Tcf3 is upregulated in skin wounds and demonstrate that Tcf3 overexpression accelerates keratinocyte migration and skin wound healing. Promoter analysis and binding studies reveal Stat3 as upstream regulator of Tcf3, which in turn rescues defective cell migration in Stat3-null cells. Mechanistically, we show that pro-migration effects are non-cell autonomous and occur independent of Tcf3/β-catenin interactions of Wnt signaling. Finally, we identify Lipocalin-2 downstream of Tcf3 as the key secreted factor that promotes cell migration in vitro and wound healing in vivo. Our findings provide new insights into the molecular controls of wound-associated cell migration and identify potential therapeutic targets for the treatment of defective wound repair.

DIRECT EVIDENCE BY IN VIVO CLONAL ANALYSIS THAT PROXIMAL TUBULE EPITHELIA DEDIFFERENTIATE TO MEDIATE REPAIR AFTER KIDNEY INJURY

Tetsuro Kusaba, Matthew Lalli, Akio Kobayashi, Benjamin D. Humphreys
Renal Division, Brigam and Women's Hospital, Boston, MA, United States

New treatments for acute kidney injury require a detailed understanding of the mechanisms of proximal tubule repair after injury but a role for intratubular progenitors remains controversial. To define the proliferative potential of differentiated epithelia, we generated a knockin mouse line expressing CreERt2 recombinase in the proximal tubule-specific sodium dependent inorganic phosphate transporter SLC34a1 locus (SLC34a1-CE). After crossing with a reporter line, tamoxifen-dependent recombination was strictly limited to the proximal tubule, with 100% efficiency in the S1 and S2 segments, and up to 65% efficiency in the S3 segment. In maximally labeled nephrons, there was no dilution of genetic label 14 days after injury, showing that intratubular, differentiated cells are wholly responsible for repair without contribution from any other cell source. To assess proliferative potential of individual, we performed clonal analysis of single differentiated tubule cells, after one cycle of ischemia-reperfusion injury and repair. During injury, all labeled cells in the inner cortex expressed the injury marker Kidney Injury Molecule (KIM)-1. Severely injured tubules contained genetically labeled epithelial cells that had a flattened, mesenchymal morphology and were positive for both Ki67 and the mesenchymal marker, vimentin. Thus injured proximal tubular cells underwent dedifferentiation and actively proliferated early after injury. Once repair was complete 14 days later, labeled clones were no longer proliferating and no longer expressed either KIM-1 or vimentin. Average clone size in the inner cortex increased from 1.09 + 0.09 to 1.45 + 0.27 ($p < 0.01$) cells per clone with a reduction in the fraction of single cell clones from 85.9 + 14.3 to 52.9 + 17.8 % ($p < 0.005$). The number of clones consisting of 5 or more cells increased from 0 % before injury to 9.12 + 13.3% ($p < 0.05$) after injury, suggesting that certain clones underwent several rounds of cell division during repair. In primary culture, genetically labeled proximal tubule cells also both proliferated and expressed injury and mesenchymal markers, consistent with our in vivo observations. These results indicate that (a) differentiated epithelia undergo proliferative expansion after injury by transient dedifferentiation and not by a stem or progenitor cell-based mechanism, (b) that most cells proliferate only once or twice during repair (c) but that clones are capable of higher rates of division in areas of more severe damage. Strategies aimed at increasing survival of differentiated cells and enhancing their ability to proliferate after injury should be pursued in order to develop new therapies.

T-1132

THE LUMINAL PROGENITOR COMPARTMENT OF THE NORMAL HUMAN MAMMARY GLAND CONSTITUTES A UNIQUE SITE OF TELOMERE DYSFUNCTION

Nagarajan Kannan[1], Nazmul Huda[2], LiRen Tu[2], Radina Droumeva[1], Geraldine Aubert[1], Ryan Brinkman[1], Peter Lansdorp[1], Satoshi Abe[2], Connie Eaves[1], David Gilley[2]
[1]Terry Fox Laboratory, British Columbia Cancer Agency, Vancouver, BC, Canada, [2]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, United States

Telomere dysfunction-associated genomic instability and elevated activity of telomerase are common features of early stage breast cancers and these changes have been reported to appear in normal human mammary cells that have been extensively passaged *in vitro*. However, little is known about telomere length regulation in the normal human mammary gland. To address this question, we isolated 3 subsets of mammary epithelial cells and the associated stromal cells (depleted of hematopoietic cells and endothelial cells) at >95% purity by fluorescent-activated cell sorting of suspensions prepared from normal reduction mammoplasty tissue obtained from 37 women ranging in age from 17-69 years old. Aliquots of these isolates were then assayed for their in vitro clonogenic cell content as well as their telomere length, evidence of telomere-associated DNA damage and expression of telomerase. The 3 mammary epithelial subsets isolated were basal cells (BCs), and 2 subsets of luminal cells, one of which contains all of the luminal progenitor activity (LPs) and one which lacks such cells (LCs). BCs were prospectively isolated on the basis of their high expression of CD49f and low expression of EpCAM and were found to be highly and selectively enriched in cells with clonogenic myoepithelial±luminal differentiation potential *in vitro* (~20% purity). This subset is also known to contain cell able to regenerate complete gland structures *in vivo* in xeno-transplanted immunodeficient mice. The LPs were isolated on the basis also of their positive expression of CD49f but coupled with high levels of expression of EpCAM. They were confirmed to contain clonogenic cells restricted to luminal differentiation at a purity of ~25%. LPs are thus assumed to represent a stage of differentiation that is intermediate between BCs and LCs.

Telomere length measurements were performed on extracts of pooled cells from each subset by Southern blot (13 samples) and Q-PCR (12 samples) and on single cells by Flow-FISH (3 samples). In every case, the LPs, independent of donor age, were found to have characteristic shorter telomeres (~5 kb) than in the BCs (~8 kb). Gene expression analysis identified significantly elevated levels of DNA damage response (DDR) genes such as *MRE11, RAD50, ATM and ATR* in LPs compared to BCs. We also found that telomere repeat-binding factor (TRF)-2 co-localized with DDR proteins, namely NBS1, MRE11, RAD50, γ-H2AX and 53BP1, at the site of the telomeres within >95% of individually examined LP nuclei (~10 telomere dysfunction-induced foci per LP nucleus). In contrast, such foci were rare in BC nuclei (<5%) isolated from the same tissue samples. The persisting high clonogenic activity of the LPs may be partially explained by the elevated telomerase activity also exclusively displayed by these cells. Interestingly, this latter potential protective mechanism declines with age (r^2=0.5, p<0.009). Taken together, these results reveal marked and previously unappreciated differences in the telomere biology of different subsets of primitive normal human mammary cells. The demonstration of chronically dysfunctional telomeres unique to LPs has potentially important implications for normal mammary tissue homeostasis as well as the development of certain breast cancers.

DISTINCT CILIARY PHENOTYPES IN POLYCYSTIC KIDNEY DISEASE AND CILIOPATHY INDUCED PLURIPOTENT STEM CELLS

Benjamin S. Freedman[1], Albert Q. Lam[1], Jamie L. Sundsbak[2], Rossella Iatrino[1], Sarah J. Koon[2], Xuefeng Su[1], Jing Zhou[1], Laurence Daheron[3], Peter C. Harris[2], Joseph V. Bonventre[1]

[1]Renal Division and Center for PKD Research, Brigham and Women's Hospital/Harvard Stem Cell Institute, Boston, MA, United States, [2]Nephrology and Hypertension/Translational PKD Center, Mayo Clinic, Rochester, MN, United States, [3]iPS Core Facility, Harvard Stem Cell Institute, Cambridge, MA, United States

Since pluripotent stem cells are epithelial cells, they hold unique promise for investigating epithelial cell biology and disease. The primary cilium, an apical membrane organelle, was recently identified as central to a family of diseases known as the ciliopathies. Polycystic kidney disease (PKD) is a very common, multi-organ ciliopathy in which epithelial cysts and fibrosis replace the normal kidney architecture. To model PKD in human cells, fibroblasts with characterized mutations from three autosomal dominant (ADPKD) and two autosomal recessive (ARPKD) patients were reprogrammed into induced pluripotent stem (iPS) cells, which could differentiate into diverse tissue types. Undifferentiated iPS and embryonic stem cells elaborated primary cilia and expressed endogenous polycystin (PC)-1 and -2. Polycystin expression levels and rates of proliferation, apoptosis, ciliogenesis, and ciliary length appeared similar in PKD iPS cells and healthy controls. However, a defect in PC2 localization to the primary cilium was

found in ADPKD iPS cell lines: in all three patients, PC2 was detectable in cilia at only one-fourth the frequency seen in ARPKD and healthy control lines. Similarly, somatic epithelial cells and hepatoblasts/biliary precursors differentiated from ADPKD iPS cells had ~50 % fewer cilia with detectable PC2, compared to controls, whereas normal PC2 localization was observed at the endoplasmic reticulum and plasma membrane. Single PKD1 mutations were identified in ADPKD patients and iPS cells, suggesting that the defect did not require loss of heterozygosity. Overexpression of wild-type PC1, but not a carboxy-terminal truncation mutant, in cultured mouse kidney cells caused a 3-5 fold increase in endogenous PC2 levels at the cilium. These results suggest that wild-type but not mutant PC1 enhances PC2 trafficking to cilia. To investigate this mechanism in other ciliopathies comprising a spectrum of multi-organ defects alongside PKD, additional fibroblasts were reprogrammed from patients with Bardet-Biedl Syndrome (BBS) or Meckel Syndrome (MKS). In contrast to ADPKD, neither BBS nor MKS iPS cells exhibited reduced PC2 at the cilium. However, cilia from MKS iPS cells from both patients were twice as long as cilia from BBS, PKD, and control iPS cells, and frequently displayed bulbous or curled ends. These results suggest that iPS cells can recapitulate distinct ciliary disease phenotypes, which may underlie differences in the pathophysiology of different ciliopathies. iPS cells can thus be used to inform human epithelial disease mechanisms and potentially guide the development of therapeutics and regenerative approaches.

Purpose: Maintenance of the ocular surface by limbal epithelial stem cells (LESCs) is essential to preserve the corneal transparency required for vision. Recently our group has identified within the limbus (the transition zone between the central cornea and the conjunctiva) a candidate for the LESC niche: the limbal crypts (LCs). The aim of this study was to demonstrate that the LCs are the reservoir for LESCs but also to identify the putative crosstalk between LESCs and stromal cells taking place in this specific area.
Methods: In vitro clonal analysis was performed to assess the growth potential of LC epithelial cells in comparison to epithelial cells from non-crypt rich areas isolated from human corneal-scleral rims. Transmission electron microscopy followed by serial block-face scanning electron microscopy, manual segmentation and 3D reconstruction were used to image and characterize putative LESCs within their niche.
Results: LC epithelial cells were able to generate holoclones in vitro demonstrating their high growth potential and stem cell characteristics. Imaging LCs by transmission electron microscopy revealed a small size and poorly differentiated “stem-like” cell population closely associated with the underlying stromal fibroblast-like cells, suggesting a possible cell-to-cell interaction. These observations were confirmed by serial block face SEM that highlighted, for the first time, a direct contact between putative LESCs and the surrounding stromal fibroblast-like cells.
Conclusion: These observations directly support the emerging concept that cellular crosstalk maintains cell stemness at the corneal limbus as seen in other epithelial stem cell niches.

DYSREGULATION OF NICHE SIGNALS PROMOTE SQUAMOUS METAPLASIA OF HUMAN LIMBAL EPITHELIAL STEM CELLS

Supaporn Khramjuntuk, Praewphan Ingrungruanglert, **Nipan Israsena**
Chulalongkorn Univ, Bangkok, Thailand

Stem cell niche, a microenvironment where stem cells reside, is widely believed to provide important stimuli for stem cell maintenance. Perturbation of tissue-specific niche signals can disrupt tissue homeostasis and involved in disease pathogenesis . For corneal epithelium, it is frequently observed that diseases which cause dry eyes could change non-keratinized stratified ocular surface epithelia into keratinized squamouse epithelia. Yet, the molecular

mechanism for this transdifferentiation is largely unknown. The purpose of this study is to investigate the effect of air exposure on limbal epithelial stem cells(LESCs)and niche cells. Our real-time PCR and immunohistochemistry studies demonstrated that when human limbal explants were cultured with air exposure, there was an up-regulation of TGF-β1 and gremlin, a known BMP antagonist, expression in the superficial layer of limbal epithelial. TGF-β promoted epithelial-mesenchymal change of LESCs as demonstrated by up-regulation of N-cadherin,vimentin, fibronectin,and transcription factor that promote EMT such as slug and snail, In contrast, inhibition of BMP signaling by coculture LESC s on limbal stromal cells overxpressing BMP antagonist resulted in ectopic expression of squamous epithelial specific marker, cytokeratin 1 and 10. Chromatin immunoprecipitation studies showed that TGF-β reduced phosphorylated smad-1 binding on p63 and pax6 promoter. Our data suggest that dysregulation of TGF-β/ BMP signaling may play a role in the squamous metaplasia of LESCs.

REDUCTION IN MTDNA COPY NUMBER GENERATES CANCER STEM CELLS AND INDUCES EPITHELIAL-MESENCHYMAL TRANSITION AND IN HUMAN MAMMARY EPITHELIAL CELLS.

Manti Guha, Satish Srinivasan, Anna Kashina, Gordon Ruthel, Narayan Avadhani
Animal Biology, University of Pennsylvania, Philadelphia, PA, United States

Mitochondrial DNA (mtDNA) copy number reduction induces
a calcium-calcineurin dependent mitochondria-to-nucleus retrograde signaling pathway that alters nuclear gene expression and culminates in tumorigenic phenotype in a variety of immortalized cell lines. MtDNA copy number reduction induces epithelial to mesenchymal transition (EMT) in human mammary epithelial cells (hMECs) - MCF10A (non-carcinoma) and MCF7 (carcinoma). This signaling in hMECs induces cellular plasticity to a fibroblast-like morphology and loss of contact inhibition, ultimately conferring increased migratory capacity and invasive phenotype. Interestingly, hMECs with reduced mtDNA copy number had a significant population of $CD44^{high}/CD24^{low}$ cells, a characteristic of mammary cancer stem cells. Moreover, mtDNA copy number reduction generates non-adherent floater-cells with self-renewal capacity which remained viable for ≥ 45days in both 2D monolayer and 3D mammosphere cultures. Additionally, mitochondrial stress signaling induces the expression of mesenchymal markers Snail, Slug, Twist, MMP9, fibronectin and vimentin and is accompanied by loss of expression of epithelial markers e-cadherin and ESRP1 indicative of an EMT. Remarkably, these EMT- like changes are reversed by restoring the mtDNA content indicating that mitochondrial stress signaling drives these events. Our findings suggest a paradigm shift in which mitochondrial genome is a regulator of breast cancer stem cells and EMT. Since breast cancer stem cells are primarily responsible for evading conventional therapy, in future pharmacologic manipulation of mtDNA copy number and intervention of the mitochondrial retrograde signaling pathway may be of therapeutic benefit in metastatic breast tumors.

GLOBAL GENE EXPRESSION AND CHEMICAL GENOMICS OF NGF INDUCED ACTIVITY IN PC12 CELL DIFFERENTIATION

Chia-Nan Liao[1], Jack Yu-Shih Lin[3], Mu-Hua Chung[4], Akon Higuchi[2], Qing-Dong Ling[4]
[A]Graduate Institute of Systems Biology and Bioinformatics, [B]Department of Chemical & Materials Engineering, [1]National Central University, Chungli, Taiwan, [2]Department of Ophthalmology, Taipei Medical University Municipal Wan-Fang Hospital, Taipei, Taiwan, [3]Cathay Medical Research Institute, Cathay General Hospital, New Taipei City, Taiwan

The roles of nerve growth factor (NGF) in the treatment of various ocular diseases have been widely investigated both in vitro and in vivo, with growing evidence of associated NGF-pathway alterations. NGF was known to be involved in the modulation of the homeostasis of the ocular surface, as well as the retina and optic nerve. These preliminary clinical reports led us to investigate, through high throughput experiments and system biology analys-

is, the genes and pathways associated with NGF induced neuronal differentiation in PC-12 cells. In this study, after cluster analysis and heat map generation, we identified 2020 NGF-induced genes with altered expression over time. Cross-matching with the KEGG database revealed 830 genes; among which, 395 altered genes were found to have 2-fold increase in gene expression over a two hour period. We then identified 191 associated biologic pathways in the KEGG database; the top 15 pathways showed correlation with neural differentiation. These include the neurotrophin pathways, MAPK pathways, genes associated with axonal guidance and the Wnt pathways. In conclusion, we have established a model system that allows one to systematically characterize the functional pathway changes in a group of neuronal population after an external stimulus. In the present study, we found that after NGF administration in PC12 cells, there is an increase in the number of pathways associated with neuronal differentiation and proliferations. The activation of these pathways may be part of the therapeutic mechanism behind which, NGF administration, either alone or combined with other growth factors, is able to offer a protective role for retinal ganglion cells from degenerative events.

α-E-CATENIN CONTROLS DENTAL CELL PROLIFERATION AND DIFFERENTIATION IN ODONTOGENESIS

Chun-Ying Li, Ophir D. Klein
Orofacial Sciences, UCSF, San Francisco, CA, United States

The presence of adult stem cells makes mouse incisors unique compared with molars, because incisors are able to grow continuously throughout the life of the animal. During early tooth development, oral epithelial cells proliferate, invaginate into the underlying mesenchyme, and differentiate into various cell types at later stage. During this process, it is thought that some of the proliferating cells maintain their embryonic characters and become adult stem cells after the incisors are fully formed. It is still unknown how the formation of different cell types, including adult stem cells, is regulated during tooth formation. Here, we show that ablation of α-E-catenin in murine tooth epithelium using K14-Cre induces arrest of tooth bud invagination. Mutant dental epithelium showed abnormal cell polarity at the leading edge, disoriented mitotic spindles, and abnormalities in cell differentiation in the basal layer. The surrounding dental mesenchyme exhibited abnormal condensation and had decreased proliferation. *In situ* hybridization showed that the expression of *Pax9*, *Bmp4* and *Shh*, factors critical for proper tooth development, was decreased. Collectively, these data indicate that α-E-catenin is required for proper cell proliferation and differentiation during formation of the tooth germ. Our findings support a model in which α-E-catenin regulates differentiation of progenitor cells into different cell types in the basal layer of epithelium, and these epithelial cells secrete signaling molecules that regulate dental mesenchyme development.

Embryonic Stem Cell Clinical Application

TOWARDS A MACACA FASCICULARIS MODEL FOR AN AUTOLOGOUS TRANSPLANTATION OF IPSC-DERIVED HEMATOPOIETIC CELLS.

Leïla Maouche-Chrétien[1], Soumeya Abed[1], Alisa Tubsuwan[2], Bokojang Chaichompoo[1], In Hyun Park[3], Aïssa Benyoucef[4], Marine Granger-Locatelli[1], Françoise Pflumio[4], Stéphane Prost[1], Emmanuel Payen[1], Geaorge Q Daley[5], Stany Chrétien[1], Philippe Leboulch[1]
[1]INSERM/CEA/iMETI, Fontenay Aux Roses, France, [2]Mahidol university, Bangkok, Thailand, [3]Yale University, New Haven, CT, United States, [4]INSERM/CEA/iRCM, Fontenay Aux Roses, France, [5]HHMI/Children's Hospital Boston/Harvard Medical School, Boston, MA, United States

Induced pluripotent stem cells (iPSCs) are an invaluable source of material for stem cell-based therapies. However, their capacity to give rise to any functional cell type and their therapeutic potential in vivo have not yet been demonstrated. For practical and financial reasons, most in vivo studies are performed in mice and not in large an-

imals, although monkeys are much more closely related to human. Indeed, validation of iPSCs-derived cell-based therapy in simian models is an essential step before iPSCs can be used in humans for regenerative medicine. To advance in this exciting field, we generated iPSCs from primary fibroblasts and bone marrow mesenchymal stem cells of two Macaca fascicularis (cynomolgus) babies. We used RT-PCR, flow cytometry and immunofluorescence assays to confirm the expression of the pluripotent endogenous genes OCT3/4, NANOG, SOX2, REX-1, KLF4, Myc and SSEA4. Intramuscular injection of cy-iPSCs into immunocompromized mice induced the development of teratomas containing tissues of the three germ layers, validating the pluripotency of the cy-iPSCs.
Our aim is to perform autologous transplantation with cy-iPSCs-derived hematopoietic cells into the monkey donor after myeloablation. As a first step, we worked on the optimization of hematopoietic differentiation protocols using co-cultures and embryoid body strategies in presence of three cocktails of hematopoietic cytokines. One protocol was chosen and a hematopoietic differentiation kinetic was followed over 3 weeks by time-lapse FACS analysis and colony forming cells (CFCs) assays to identify emerging cells with hemangioblastic, hematopoietic and endothelial phenotypes with or without CFCs capacity. Fewer than 1/200 CD34+ cells were able to form hematopoietic colonies on methylcellulose, whereas most cells positive for both CD34 and CD45 did form colonies. We used RT-qPCR to analyze the expression of genes associated with mesodermal and hemato/endothelial differentiation during development (among which BRACHYURY, CDX-4, VEGF-R2, SCL, GATA-2, RUNX-1 and GATA-1); This study during 3 weeks of differentiation showed that hematopoietic gene expression was consistent with the hematopoietic cell phenotype as determined by FACS and CFC assays. To evaluate the engraftment potential of cy-iPSC-derived hematopoietic cells, we injected various cell populations (CD34+, CD45+, CD34+ CD45+, total fraction of SSE4- cells) into the femur of sublethally irradiated NSG mice. Among the 30 mice treated, none developed teratoma and seven mice showed engraftment 5 weeks after the injection of Day 20 or a mixture of Days 14 and 18 of differentiated cells. The engraftment was quite low and transient and involved CD34+, CD20+ and CD14+ cells. The species barrier and the origin of the cells could explain this weak result. Large-scale hematopoietic differentiation is now in progress to allow transplantation of CD34+, CD34+CD45+ sorted cells, and 12 differently aged SSEA4- cell fractions, into donor monkeys, and thereby evaluate their capacity for short or long-term hematopoietic engraftment to bring a proof of concept for iPSC-based therapies.

T-1143

CLASSICAL BROWN ADIPOCYTES GENERATED FROM HUMAN PLURIPOTENT STEM CELLS: TOWARDS THERAPUETIC DEVELOPMENT FOR THE TREATMENT OF METABOLIC DISORDERS

Miwako Nishio[1], Masako Nakahara[1], Koichi Saeki[2], Mamoru Hasegawa[2], Akira Yuo[1], Kumiko Saeki[1]

[1]Department of Disease Control, Research Institute, National Center for Global Health & Medicine, Tokyo, Japan, [2]DNAVEC Corporation, Ibaraki, Japan

Brown adipose tissue (BAT) is recognized as a new therapeutic target of obesity and obesity-related metabolic disorders. However, it is hardly possible to obtain enough amounts of functional human BAT samples from living individuals because of ethical and technical hurdles. For stable provision of a sufficient volume of functional human brown adipocytes (BA), an establishment of a method for a direct differentiation of human pluripotent stem cells (hPSCs) into functional classical BA is of great use.
We recently established a method to produce high-purity classical BA from hPSCs including human embryonic stem cells (hESC) and human induced pluripotent stem cells (hiPSC) (Nishio M. et al., Cell Metabolism 16: 394-406, 2012, International Patent pending). At the ISSCR in 2012, we reported that hPSC-derived BA exerted blood glucose level-lowering effects in short-term (~ 24h) transplantation assays. Here we examined longer-term (~ 30 days) effects of hPSC-derived BA on glucose metabolism. Immunocompromised NOG mice, which lack entire lymphocytes, were subcutaneously transplanted with hESC-derived BA and fasting blood glucose levels were measured at Day 10, Day 21 and Day 30. Although we observed statistically significant reductions of fasting blood glucose values in hESC-derived BA-transplanted mice at Day 10 and Day 21, a reduced fasting blood glucose level was detected only in one mouse out of three at Day 30. Thus, subcutaneous transplantation is not suited for longer-term (> 1 month) transplantation experiments. Recently, it was reported that peritoneal transplantation, but not subcutaneous trans-

plantation, of murine BAT exerted long-term (12 ~ 16 weeks) glucose metabolism-improving effects. We are currently studying long-term effects of peritoneally transplanted hPSC-derived BAs on lipid and glucose metabolisms. Our system is based on a completely feeder-free culture and the only xenogenic material used in our method are bovine serum albumin, which can be substituted by recombinant human albumin, and porcine gelatin, which has already been used for clinical purposes. By up-grading the current system to meet with the good manufacturing practice (GMP) grade, we are working toward an establishment of a protocol of cell therapy for metabolic disorders using hiPSC-derived BAs. Also, we are searching for novel human BA-derived adipokine(s) as a potential therapeutic agent for metabolic syndrome using hESC/hiPSC-derived BAs as research tools. Finally, we are studying the transcriptional network that regulates human BA differentiation by applying a Predictive MicroArray Semi-Kinetic (PMASK) analytic system to discover a novel molecular target of drug discovery for the treatment of metabolic syndrome. We will show our recent results on those issues.

LONG TERM SELF RENEWAL OF HUMAN PLURIPOTENT STEM CELLS UNDER HUMAN PLACENTA DERIVED CELLS CONDITIONED MEDIUM WITHOUT BASIC FIBROBLAST GROWTH FACTOR SUPPLEMENTATION

Ji Hye Jung[1], Seung Jin Lee[1], Ji Hye Kim[1], Yong Park[2], Byung Soo Kim[2]
[A]Department of Biomedical and science, [B]Department of Internal Medicine, Korea University Medical Center, Seoul, Korea., [1]Institute of stem cell research, Korea University, seoul, Korea, Republic of

Human embryonic stem cells (hESCs) and Human induced pluripotent stem cells (iPSCs) have emerged as a promising source for regenerative medicine. Establishment of an animal substance-free and feeder cell-free environment that supports the self-renewal of human pluripotent cells has been a major goal in the field since hESCs were first derived on fetal mouse fibroblasts. The presence of animal proteins, feeder cells in human pluripotent cell cultures can cause problems related to immunogenicity, microbial and viral contamination and variability of experimental results.
However, many researchers still widely use complex mixture of animal proteins and undefined human proteins that prohibitively expensive for make dose conditions. Previously we reported that feeder formed from human placenta derived cells support prolonged undifferentiated propagation of hESCs without basic fibroblast growth factor (bFGF) supplementation. In this study, we evaluate human placenta derived feeder cells conditioned medium (PCCM) that, with gelatin as an extracellular matrix, allows the long-term culture of hESCs and iPSCs without bFGF. The hESCs and iPSCs self-renewed for at least 6 months (26 passages), after which the cells could *in vitro* differentiation containing cell lineages of all three germ layers. Furthermore, maintaining cellular homogeneity with OCT4, SSEA-4, TRA-1-60, TRA-1-81 positive cells. Using human cytokine antibody array and ELISA, that human placenta derived feeder cells secreted higher amounts of the GRO-a, IL-8, MCP-1, TIMP-2 than the control. Our findings demonstrate, for the first time, identifying novel factors need for hESCs and iPSCs long-term self-renewal and maintenance except for bFGF. This nearly xeno-free and feeder cell-free culture system may be useful for the both hESCs and iPSCs based cell therapies for clinical applications.

Cells Center, Tzu-Chi Univ, Hualien, Taiwan, [5]Division of Infertility Clinic, Lee Women's Hospital, Taichung, Taiwan, [6]Biomedical Engineering Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan

Human embryonic stem cells (hESCs) provide a potentially unlimited source for various cell therapies because of their indefinite propagation in vitro and their pluripotent differentiation potential. However histocompatibility is the first obstacle encountered in their regenerative medicine applications. Therefore detailed characterization of the blood-histotypes of the human ES cells is vital to the construction of a hESC bank. Here we report the high-resolution sequence based typing (SBT) of HLA-A,-B,-C,-DQ and -DR loci and acquire complete typing results of eight hESC lines in Taiwan. In our study, there are several hESC lines predicted serologically homozygous at single or double HLA loci: one is homozygous for HLA-A, three are homozygous for HLA-C; one is homozygous for both HLA-C and HLA-DQ loci and one is homozygous for both HLA-A and HLA-C loci. Three of these hESC lines are A blood type (A/A or A/O), three are type O and two are type B (B/B). These documented blood-histotypes of human embryonic stem cell lines as a whole provide detailed reference information for their future use in cell transplantation. The common Asian-specific haplotypes identified and their reported associations with hyper-sensitivity to medications also provide hints for the potential to build drug testing platforms using differentiated tissues derived from these banked human ES cells.

Epithelial Cells (Not Skin)

WNT SIGNALING PATHWAY REGULATES THE DIFFERENTIATION OF HUMAN LIMBAL STEM CELLS VIA THE FRIZZLED 7 RECEPTOR

Sophie X. Deng, Hua Mei
UCLA, Los Angeles, CA, United States

Wnt signaling pathway plays an essential role in regulating epithelial stem cell maintenance and differentiation. The possible function of Frizzled (Fz), the co-receptor of Wnt ligand, in regulating limbal stem cells (LSCs) is investigated. Ten Fz members were screened and four Fz receptors (Fz1, Fz4, Fz7 and Fz10) showed consistently higher expressions in the limbus than in the cornea through quantitative real-time PCR. Immunohistochemistry revealed that Fz7 but not Fzq and FZ4 was predominantly expressed in the basal layer of limbal epithelium. The expression of Fz7 was co-localized with the putative stem cell markers including p63α, N-cadherin and K14 and was mutually exclusive to the expression of cornea epithelial maturation marker K12. The expression of Fz7 was higher in the SSEA4- limbal epithelial cells that contain a larger portion of the stem cell population than in the SSEA4+ population. After expansion of the LSCs on 3T3 feeder, the expression level of putative stem cell markers, ABCG2, ΔNp63 and N-cadherin decreased by 77%, 44%, and 73%, respectively (all $p<0.0001$). Interestingly, the expression of Fz7 was also significantly decreased by 82% ($p<0.0001$). After the Fz7 expression was knocked down using shRNA in primary human limbal epithelial cells the expression of ABCG2, ΔNp63α and K14 was decreased by 25%, 20%, and 20%, respectively (all $p<0.05$) compared to the control while the expression of N-cadherin and K12 did not differ from the control population. The colony forming efficiency from the Fz7KD cells was 63% and 38% lower in passage 1 and 2, respectively compared to the control. The findings suggest that Fz7 may be a niche factor of limbal stem cells. Wnt signaling might maintain the undifferentiated state of limbal stem/progenitor cells via the Fz7 receptor.

Hematopoietic Cells

TIME DEPENDENT EFFECT OF THE COMBINATION THERAPY WITH ERYTHROPOIETIN AND GRANULOCYTE COLONY STIMULATING FACTOR IN HYPOXIC ISCHEMIC BRAIN INJURY

jihea yu, junghwa seo, jiyong lee, yanghyun cho, sungrae cho

Department & Research Institute of Rehabilitation Medicine, Yonsei University College of Medicine, seoul, Korea, Republic of

Objective: Erythropoietin (EPO) and granulocyte-colony stimulating factor (G-CSF) are likely to play a broad role in the brain. We investigated the effects of the combination therapy with EPO and G-CSF in hypoxic-ischemic brain injury during acute, subacute, or chronic phase.
Methods: A total of 79 C57BL/6 mice with hypoxic-ischemic brain injury were randomly assigned to acute phase (days 1-5), subacute phase (days 11-15) or chronic phase (days 28-32) group. All of which were treated with G-CSF (250 μg/kg) and EPO (5000 unit/kg) or saline daily for 5 consecutive days. Behavioral assessments and immunohistochemistry for angiogenesis, neurogenesis and astrogliosis were performed with an 8-week follow-up. Hypoxia-inducible factor-1α (HIF-1α) was also measured by western blot analysis.
Results: The combination therapy with EPO and G-CSF in acute phase significantly improved rotarod performance (154.25±16.18 sec), In the cylinder test, the difference (Δ) relative to control group in the percentage of wall contacts with contralateral limb was significantly greater in mice treated with EPO and G-CSF in acute phase (14.50±1.73%) compared to mice treated in subacute phase (5.17±2.24%) and chronic phase (-0.33±3.83%) (p=0.002). In ladder walking test, mice treated in acute phase (1.67±0.33%) and subacute phase (2.0±0.68%) showed a significant reduction in the difference (Δ) relative to control group in the percentage of the slips among total steps with hemiplegic forelimbs compared to mice treated in chronic phase (-0.50±0.50%). The acute phase treatment significantly increased CD31(PECAM-1)$^+$ (p=0.001 in frontal cortex, p<0.001 in striatum) and α-smooth muscle actin (α-SMA)$^+$ (p<0.001 in frontal cortex, p=0.012 in striatum) vessels density in frontal cortex and striatum. The acute phase treatment also increased BrdU$^+$/PSA-NCAM$^+$ neurogenesis in subventricular zone (p<0.001), but decreased astroglial density in striatum (p<0.001). Furthermore, the treatment in acute phase significantly increased the HIF-1α expression in cytosol (p=0.007) and nucleus (p=0.048), whereas the treatment in chronic phase did not change the HIF-1α expression, consistent with behavioral outcomes.
Conclusion: Induction of HIF-1α expression by the combination therapy with EPO and G-CSF synergistically enhances not only behavioral function but also neurogenesis and angiogenesis while decreasing the astroglial response in a time-dependent manner.

T-1152

GENERATION AND CHARACTERIZATION OF MACROPHAGES DERIVED FROM MOUSE UTERINE STEM CELLS IN A FEEDER LAYER-LIKE LONG TERM CULTURE SYSTEM

Kota Hatta, Yuemei Zhang, Zhuo Sun, Richard D. Weisel, Ren-Ke Li
Univ of Toronto, Toronto, ON, Canada

The endometrium is a unique tissue in its ability to regenerate. During menses or labor decidua is shed and lost, however new tissue, including the vasculature, is regenerated. Indeed, the endometrium is a rare and highly active site of non-pathological angiogenesis in the adult body. These properties lead us to hypothesize that the uterus contains stem cells that positively contribute to angiogenesis. We sought to culture and characterize uterine stem-cell derived pro-angiogenic macrophages. Using a mouse model, we performed in vitro studies of uterine cells. Mouse uteri were dissected, enzymatically digested and released cells were cultured in IMDM 10% FBS. As the culture progressed, adherent macrophages rounded and emerged above other cells. These rounded macrophages were loosely adherent and could be isolated by tapping the dish or gentle pipetting. The observations (of rounding immune cells forming from adherent cells) were similar to traditional feeder layer cultures of fibroblast cell lines used to differentiate hematopoietic lineage cells. In our primary cell cultures, we identified CD11b+ macrophages rounding above CD90.2- smooth muscle actin+ cells. Future work will examine the potential of uterine CD90.2-smooth muscle actin+ cells as feeder layer cells supporting hematopoiesis, and the angiogenic potential of rounding CD11b+ macrophages. The work supports the notion that the uterine niche is equipped to independently support part of the tissue regeneration that occurs in normal uterine physiology via local, tissue resident stem cells.

T-1153

EXPRESSION OF EBF2 IN OSTERIX-POSITIVE IMMATURE OSTEOBLASTIC CLELS DEFINES A NICHE FOR HEMATAPOIETIC STEM CELLS

Christoph Hinzen, Ursula Zimber-Strobl, **Matthias Kieslinger**
Institute of Clinical Molecular Biology and Tumor Genetics, Helmholtz Zentrum München, Munich, Germany

Hematopoietic Stem Cells (HSCs) reside in specialised bone marrow (BM) microenvironments, which govern their cell fate. During homeostasis, some HSCs within this niche are kept dormant, preserving long-term self-renewal potential, while others self- renew to replenish the hematopoietic system. The stem cell niche mediates signals inducing quiescence, proliferation or differentiation in HSCs. While HSCs themselves are well defined, the composition of the niche is still unclear. Various cell types like mesenchymal stem cells (MSCs), sinusoidal endothelial cells, osteoblasts and adipocytes have been implicated in homing, mobilisation and maintenance of HSCs.
The transcription factor Ebf2 is expressed in mesenchymal progenitors including mesenchymal stem cells (MSC), immature osteoblastic cells and adipocytes, but not in hematopoietic cells. HSCs localise to Ebf2-expressing cells at the endosteum and deletion of Ebf2 in mice results in an age-dependent loss of hematopoietic cells and decreased frequencies of HSC. Purified Ebf2-expressing cells of the bone marrow demonstrate a need for Ebf2 and cell-cell contact in the support of HSC, clearly implicating Ebf2 in the niche-dependent support of HSC. However, as Ebf2 is expressed by various mesenchymal cell lineages, the individual contribution of these lineages is not clear. To address this question, we have generated Ebf2 conditional knock-out mice, and crossed them with MSC, adipocyte and osteoblast-specific Cre lines. Deletion of Ebf2 specifically in immature osteoblastic cells using the Osx-Cre line fully recapitulates the defect in HSC maintenance of the conventional Ebf2 knock-out, whereas loss of Ebf2 in adipocytes has no detectable consequences on HSC frequency. A DNA microarray analysis of Ebf2-expressing cells reveals genes involved in homing and proliferation of HSCs as down-regulated in Ebf2-deficient cells, partly explaining the observed phenotype. As Ebf2 mediates its activity in HSC maintenance directly via cell-cell contact, we conclude that immature osteoblastic cells constitute a part of the niche for HSC and we will present first data to gain a mechanistic understanding of its supportive capacity.

17β-ESTRADIOL HAS A BIPHASIC EFFECT ON THE FORMATION OF HEMATOPOIETIC STEM CELLS

Kelli J. Carroll[1], Michael C. Dovey[1], Claire C. Cutting[2], Maija K. Garnaas[2], Virginie Esain[1], Gregory Frechette[1], Daniel Gorelick[3], James M. Harris[1], Marnie Halpern[3], Wolfram Goessling[2], Trista E. North[1]
[1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA, United States, [2]Brigham and Women's Hospital/Harvard Medical School, Boston, MA, United States, [3]Carnegie Institute for Science, Baltimore, MD, United States

While intrinsic signaling pathways regulating hematopoietic stem cells (HSC) are increasingly understood, less is known about the consequences of exposure to environmental factors. Through a chemical genetic screen, estrogen-related compounds were identified as modifiers of *runx1* expression in the zebrafish. Exposure to 17beta-estradiol (E2) significantly decreased the number of *runx1+* HSCs in the AGM compared to controls by *in situ* hybridization, FACS, and qPCR. MO-knockdown and use of the nonspecific estrogen receptor inhibitor fulvestrant confirmed that estrogen was required for nascent HSC regulation and functioned through classical estrogen receptors. Using an ERE-GFP reporter and enzyme immunoassay, estrogen activity was detected in the AGM during hematopoiesis, with estrogen receptors *esr1 (esr alpha)* and *esr2a/b (esr beta)* demonstrating differential spatio-temporal expression in vascular and hematopoietic cell types. E2 treatment from 12-24 hours post-fertilization disrupted vessel formation and angiogenic sprouting, as indicated by *flk1* (*kdrl*), and altered the assignment of *ephrinb2+* arterial identity. Consistent with that phenotype, E2 exposure decreased activity in a Notch pathway-reporter line and blocked arterial expression of *deltaC* and *notch5* as well as *VEGFAa* expression, upstream of the notch cascade. Hyperactivation of either the VEGF or Notch pathways could rescue the hematopoietic defects observed following E2 exposure, confirming changes in this transcriptional network underlie the observed phenotypes. To determine whether environmental estrogens could mediate similar effects, we exposed embryos to the phytoestrogen gen-

istein, the synthetic estrogen ethinylestradiol (EE), and the xenoestrogen bisphenol A and found each decreased formation of HSCs; using fulvestrant, we confirmed the effects were at least partially dependent on estrogen receptor stimulation. In addition, EE and genistein had the ability to decrease signaling in Notch:GFP reporter fish. Interestingly, when exposure to E2 occurred after arterial establishment and initiation of blood flow, from 27-34 hpf, estrogen treatment enhanced HSC number by *in situ* and qPCR. Markers of the cell cycle including cyclinD1 and c-myc were significantly increased suggesting estrogen enhances cell cycling. This proliferative effect did not appear to be dependent on Notch or VEGF signaling as inhibition of either pathway could not block the increase in HSCs following E2 exposure. Effects of E2 on primitive hematopoiesis were also noted: E2 treatment enhanced expression of *gata1* both by *in situ* and FACS while repressing the expression of *globin*, suggesting that while estrogen enhances the self-renewal of progenitors, it may impair their differentiation into mature lineages. In an adult zebrafish marrow injury model, E2 significantly accelerated stem and progenitor cell recovery in both sexes. Intriguingly, females, with higher circulating estrogen levels, recovered better after injury than males, both in the presence and absence of exogenous estrogen. Finally, functional conservation of estrogenic effects was confirmed with a murine CFU-S_{12} assay. Together, these data identify estrogen and estrogen-related compounds as critical regulators of hematopoietic stem cell formation and proliferation and suggest a novel role for estrogen in the development of the hematopoietic niche.

DNMT3B IS DISPENSABLE FOR HEMATOPOIETIC STEM CELL FUNCTION, BUT ACTS SYNERGISTICALLY WITH DNMT3A TO CONTROL THE BALANCE BETWEEN SELF-RENEWAL AND DIFFERENTIATION

Grant A. Challen[1], Allison Mayle[2], Mira Jeong[2], Min Luo[2], Deqiang Sun[2], Benjamin Rodriguez[2], Wei Li[2], Margaret Goodell[2]

[1]*Division of Oncology; Dept of Internal Medicine, Washington University in St. Louis, Saint Louis, MO, United States,* [2]*Baylor College of Medicine, Houston, TX, United States*

DNA methylation of CpG dinucleotides is one of the major epigenetic modifications in the vertebrate genome. DNA methylation is catalyzed by a family of DNA methyltransferase enzymes comprised of Dnmt1, Dnmt3a, and Dnmt3b. In humans, somatic mutations in DNTM3A have been identified in ~20% of human acute myeloid leukemia (AML) and ~10% of myelodysplastic syndrome (MDS) patients, but the mechanisms through which these mutations contribute to pathogenesis is not well understood. Congenital mutations in DNMT3B can cause ICF (immunodeficiency, centromeric instability, and facial anomalies) syndrome. These patients exhibit chromosomal instability due to heterochromatin decondensation and demethylation of satellite DNA.

We have recently shown that Dnmt3a is essential for hematopoietic stem cell (HSC) differentiation. Conditional knockout of Dnmt3a (Dnmt3a-KO) resulted in HSCs that could not sustain peripheral blood generation after serial transplantation, while phenotypically defined HSCs accumulated in the bone marrow. Given Dnmt3b is also highly expressed in HSCs, we reasoned it may also have a specific role in HSC function. Here, we examine the role of Dnmt3b, alone and in combination with Dnmt3a inactivation, in the regulation of hematopoiesis. We performed conditional deletion of Dnmt3b in HSCs, as well as Dnmt3a and Dnmt3b simultaneously, using the Mx1-cre system. Unlike the Dnmt3a-KO HSCs, loss of Dnmt3b had a minimal impact on blood production. Even after several rounds of transplantation, Dnmt3b-KO HSCs performed similarly to controls. However, the Dnmt3ab-dKO (double knockout) peripheral blood contribution was quickly and severely diminished, accompanied by a dramatic accumulation of Dnmt3ab-dKO HSCs in the bone marrow (>50-fold), paralleling the phenotype of the Dnmt3a-KO HSC, but more extreme.

To examine the impact of loss of Dnmt3a and -3b on DNA methylation in HSCs, we performed Whole Genome Bisulfite Sequencing (WGBS) on Dnmt3a-KO, Dnmt3ab-dKO and control HSCs. While loss of Dnmt3a led to both increases and decreases of DNA methylation at distinct genomic regions, ablation of both Dnmt3a and -3b primarily resulted in loss of DNA methylation that was much more extensive than that seen in the absence of Dnmt3a alone. In addition, RNA-SEQ of the mutant HSCs revealed loss of transcriptional integrity including increased expression of repetitive elements, inappropriate splicing, and premature truncation of 3'UTRs.

These data show that Dnmt3a and -3b act synergistically to regulate HSC differentiation. The accumulation of Dnmt3ab-dKO HSCs cannot be attributed to altered proliferation or apoptosis, but rather the lack of peripheral blood contribution is due to an imbalance between self-renewal and differentiation cell fate decisions. By understanding the mechanisms through which Dnmt3a and -3b exert these effects, we should identify genes that are critical for normal hematopoietic differentiation. These genes may serve as targets for therapeutic intervention in malignancies caused by defective DNA methyltransferases. This work highlights the importance of DNA methylation in HSC cell fate decisions and further contributes to understanding the epigenetic regulation of hematopoiesis which is still poorly understood.

THE ROLE OF IGFII IN THE REGULATION OF HEMATOPOIETIC STEM CELL FUNCTION

Dolly Thomas, Andreia Gianotti Sommer, Gustavo Mostoslavsky
Medicine, Boston University School of Medicine, Boston, MA, United States

Maintenance of the hematopoietic system is dependent on the proper regulation and function of HSC (hematopoietic stem cell) populations contained within the bone marrow niche. Preliminary microarray data comparing gene expression profiles between LT-HSC (SP Lin- Sca1+ cKit+CD34-), ST-HSC (SP Lin- Sca1+ cKit+CD34+), and non-HSC of the bone marrow have revealed a significantly higher expression of IGFII within LT-HSC when compared to non-HSC populations, suggesting a potential role for IGFII in HSC regulation. In vitro methylcellulose colony forming (CFU) assays containing IGFII overexpressing HSC, have yielded a greater percentage of multi-lineage colonies indicative of the maintenance of HSC self-renewal properties. Utilizing in vivo competitive transplant assays we have shown that IGFII transduced HSC exhibit enhanced long-term donor contribution upon bone marrow transplant. We hypothesize that IGFII regulates HSC self-renewal by affecting cell cycle function, specifically by its effects on p57 expression. P57, a member of the Cip/Kip family of cyclin dependent kinase inhibitors, has recently been shown to be required for regulation of HSC quiescence and long-term self-renewal. Our studies show that lentiviral mediated overexpression of IGFII within purified HSC alters expression of p57, suggesting that an IGFII/p57 pathway is involved in the regulation of HSC function.

THE ATM-BID-MTCH2 MITOCHONDRIAL PATHWAY REGULATES HAEMATOPOIETIC STEM CELL FATES

Maria Maryanovich, Atan Gross
Biological Regulation, The Weizmann Institute of Science, Rehovot, Israel

The BH3-only BID protein plays a critical function in the death-receptor pathway in the liver by triggering mitochondrial apoptosis. Interestingly, BID is also involved in cell cycle regulation, and this function is monitored by the ATM DNA damage kinase. Recently we demonstrated that ATM-mediated BID phosphorylation plays an unexpected role in maintaining the quiescence of haematopoietic stem cells (HSCs). Loss of BID phosphorylation leads to escape from quiescence of HSCs, resulting in exhaustion of the HSC pool and a marked reduction of HSC repopulating potential in vivo. We further demonstrated that the regulation of both quiescence and survival of HSCs depends on BID's ability to regulate the levels of reactive oxygen species (ROS) at the mitochondria.
How does BID regulate mitochondrial function/ROS in the haematopoietic system? Recently we demonstrated that mitochondrial carrier homologue 2 (MTCH2), a novel protein suggested to be involved in obesity, functions as a mitochondrial receptor for BID and is essential for Fas-induced apoptosis in vivo. To investigate the role of MTCH2 in the bone marrow, we generated MTCH2 haematopoietic-specific knockout (HKO) mice using the Vav1-Cre mice. HKO mice demonstrate a decrease in long-term (LT) HSCs and expansion of common lymphoid progenitors. Interestingly, MTCH2-deletion also results in an increase in mitochondrial mass in both LT-HSCs and restricted progenitors, suggesting that changes in mitochondria function/metabolism play an important role in regulating cellular fates in the haematopoietic system.

Taken together, our data are consistent with the idea that MTCH2 is a new player in the ATM-BID pathway, and that this novel mitochondrial pathway plays a critical metabolic function in regulating HSC survival and quiescence.

T-1158

CO-INHIBITION OF THE TNF-JNK-AP1 AXIS AND NF-κB SYNERGIZE IN AML STEM AND PROGENITOR CELLS

Andrew Volk[1], Jin Li[2], Junping Xin[1], Dewen You[1], Peter Breslin[1], Wei Wei[1], Rachel Schmidt[1], Sucha Nand[1], Zejuan Li[3], Jianke Zhang[4], Jianjun Chen[3], Jiwang Zhang[1]
[1]Loyola University Chicago, Maywood, IL, United States, [2]Shanghai Normal University, Shanghai, China, [3]University of Chicago, Chicago, IL, United States, [4]Thomas Jefferson University, Philadelphia, PA, United States

Leukemic stem cells (LSCs) isolated from acute myeloid leukemia (AML) patients are more sensitive to NF-κB inhibition-induced cell death *in vitro* when compared to normal hematopoietic stem/progenitor cells (HSPCs). This suggests that blocking NF-κB could be an effective strategy for treating AML. However, the inadequate anti-leukemic activity of NF-κB inhibition *in vivo* suggests that elements within the bone marrow microenvironment might stimulate compensatory survival/proliferation signals in AML cells that can overcome the effects of NF-κB inhibition. Our data suggests Tumor Necrosis Factor-α (TNF) mediates such a signal. We found TNF levels are significantly increased in samples from most AML patients, especially AML subtypes M3, 4 and 5 when compared to samples from healthy donors. We also found that many types of AML cells produce TNF.
Stimulating HSPCs with exogenous TNF induces powerful RIP1/3-mediated necroptosis and caspase-mediated apoptosis responses, resulting in cell death and loss of normal hematopoietic function. TNF-mediated cell death in HSPCs can be partially blocked by inactivation of JNK-AP1 signaling.
In our AML model, stimulation with exogenous TNF promotes the *in vitro* growth of leukemic cells by stimulating both NF-κB and JNK-AP1 signaling. We found that while TNF-JNK-AP1 pathway activation in HSPCs leads to cell death, leukemic cells convert TNF-JNK-AP1 signaling from a death signal to a survival signal. Inactivation of any part of the TNF-JNK-AP1 signaling axis can repress the growth of leukemic cells *in vitro* and delay leukemogenesis *in vivo*. We also show that blocking any portion of the TNF-JNK-AP1 signaling axis sensitizes TNF-expressing leukemic cells, including LSCs, to NF-κB inhibitor treatment while at the same time protecting HSPCs from such treatment.
In conclusion, we found that many types of AML cells produce TNF. This TNF can act in an autocrine fashion to promote LSC survival and self-renewal, as well as in a paracrine fashion to repress normal hematopoiesis. Our studies also suggest that the inadequate ability of NF-κB inhibition to clear AML tumors *in vivo* is due to the compensatory TNF-mediated activation of the JNK-AP1 signaling axis in LSCs. Therefore, we propose that inhibition of both TNF-JNK-AP1 and NF-κB signals may provide a more thorough treatment for AML patients with elevated peripheral blood TNF.

EX VIVO EXPANDED HUMAN UMBILICAL CORD BLOOD MYELOID PROGENITORS CELLS STIMULATE VASCULAR REGENERATION

David M. Putman, Ayesh Seneviratne, David A. Hess
Department of Physiology and Pharmacology, University of Western Ontario, London, ON, Canada

Effective therapies to promote revascularization are central to the treatment of ischemic diseases including myocardial infarction, stroke and peripheral vascular disease. However, clinical implementation of cellular therapies is impeded by our limited understanding of the many cell types and signaling effectors implicated in the coordination of vascular repair. Due to recent initiatives to collect and store umbilical cord blood (UCB) for regenerative therapies, UCB-derived progenitors have emerged as a readily-available allogeneic source of pro-angiogenic cells untouched by chronic cardiovascular disease-related pathologies.
We have recently reported that human UCB-derived multipotent myeloid progenitor cells, prospectively purified based on high aldehyde dehydrogenase activity ($ALDH^{hi}$), can promote the recovery of perfusion in immunodefi-

cient mice with acute unilateral hindlimb ischemia. Intravenous transplantation of $2x10^5$ freshly isolated human UCB $ALDH^{hi}$ cells augmented reperfusion and stimulated revascularization without long-term engraftment in the ischemic limb (*Putman et al.* Stem Cells 2012). High ALDH activity enriched for cells that demonstrated increased production of pro-angiogenic cytokines by microarray, and promoted endothelial cell survival and tube formation during co-culture. Unfortunately, the rarity of $ALDH^{hi}$ progenitor cells (0.4±0.1% of total mononuclear cells) impedes clinical implementation of cell-based therapies due to difficulty achieving clinically relevant cell numbers.

To address this issue, we have optimized *ex vivo* culture protocols to increase the number of UCB $ALDH^{hi}$ cells available for therapy. UCB $ALDH^{hi}$ cells were grown on fibronectin-coated plates in serum-free, X-vivo15 media supplemented with recombinant human SCF, Flt-3L, and TPO (10ng/mL). After 6 days of culture, we observed 14.0±5.6 fold expansion in total cell number (n=10), and 13.2±2.7% of cells retained high ALDH-activity, Expanded $ALDH^{hi}$ cells maintained primitive progenitor (77.6±4.2% $CD34^+$, 48.7±7.7% $CD133^+$, 5.46±1.2% $CD117^+$) and early myeloid markers (99.9±0.2%, CD33+), an expression pattern similar to freshly isolated UCB $ALDH^{hi}$ cells (n=5). Furthermore, expanded cells maintained multipotent myeloid colony forming cell function in methylcellulose media (1 CFU in 10 cells). Remarkably, intramuscular injection of these expanded myeloid progeny into mice with acute unilateral ischemic injury stimulated robust vascular recovery with kinetics similar to uncultured UCB $ALDH^{hi}$ cells. Within 7 days post-transplantation, *ex vivo* expanded myeloid progenitors ($5x10^5$ cells) significantly accelerated the recovery of perfusion (RP) in the ischemic limb (RP=40±7%, n=8) compared to saline-injected mice (RP=25±8%, n=15, $p<0.05$), and augmented perfusion was maintained for one month post-transplantation (RP=71±16% vs 39±12%, $p<0.01$). Progenitor cell transplanted mice also showed higher $vWF^+/CD31^+$ capillary density in the ischemic limb compared to saline injected controls ($p<0.01$).

Collectively, these data indicate that UCB $ALDH^{hi}$ cells can be efficiently expanded in serum-free *ex vivo* culture without significant loss of progenitor phenotype or vascular regenerative capacity, and provide proof-of-concept data to support the clinical translation of allogeneic cell-based therapies for ischemic disease.

T-1162

EX VIVO EXPANSION OF HEMATOPOIETIC STEM CELLS CULTURED ON BIOMATERIAL HAVING DIFFERENT ELASTICITY

Jui-Hsiang Hsiao, Yu-Hsuan Chou, Pin-Yu Wang, Akon Higuchi
National Central Univ, Jhongli City, Taiwan

Umbilical cord blood (UCB) is an attractive source of hematopoietic stem and progenitor cells for hematopoietic stem cell (HSC) transplantation. However, the low number of HSCs obtainable from a single donor of UCB limits direct transplantation of UCB to the treatment of pediatric patients. In this study, we investigated the ex vivo expansion of HSCs cultured on biomaterials grafted with several nanosegments, which have different elasticity. Matrix elasticity of cell culture biomaterials plays an important role in maintenance of pluripotency and differentiation abilities of stem cells. Physical properties (e.g., elasticity) of the culture substrates can affect the stem cell fate of differentiation and pluripotency of the stem cells. Similarly, the chemical and biological properties of cell culture substrates can also affect the maintenance of pluripotency and differentiation ability of the stem cells. In this study, we prepared polyvinylalcohol-co-itaconic acid (PVA-IA) coating dishes having different stiffness from 0.022 MPa to 16.5 MPa where fibronectin or oligopeptide derived from cell binding domain of fibronectin (CS1, EILDVPST) were grafted. The elasticity of PVA-IA films were controlled by crosslinking time of PVA-IA films with glutaraldehyde (30 min-24 hrs). HSCs were isolated from UCB by Ficoll-Paque method followed by CD34 selection through magnetic associated cell sorting method (MACS). Ex vivo expansion of HSCs was the highest when HSCs were cultured on stiffer PVA-IA coating dishes without grafting of fibronectin nor CS-1 oligopeptide in HSC expansion medium. The pluripotent colony-forming units (i.e. colony-forming unit-granulocyte, erythroid, macrophage, and megakaryocyte [CFU-GEMM]) from HSCs were also found to increase with increasing the elasticity of PVA-IA coating dishes when HSCs cultured on PVA-IA coating dishes without immobilization of fibronectin and CS-1 were used for the colony-forming assay. On the other hand, when HSCs were cultured on PVA-IA coating dishes grafted with fibronectin or CS-1,

high expansion fold of HSCs was observed on the PVA-IA dishes having intermediate stiffness from 0.12 MPa to 1.5 MPa, which was more than 1.6 times higher than expansion fold of HSCs cultured on conventional tissue culture polystyrene dishes (TCPS, 12 GPa). Furthermore, HSCs cultured on PVA-IA coating dishes grafted with fibronectin or CS-1 having 12.2-30.4 MPa showed more pluripotent colony-forming units (i.e. CFU-GEMM) than those on TCPS dishes (12 GPa). This result indicates that both physical and biological properties of cell culture materials will affect the ex vivo expansion of HSCs. The biological cues of cell culture materials such as fibronectin or CS-1 grafting on the cell culture dishes seem to play a more significant role than the physical characteristics (elasticity) of cell culture materials during ex vivo expansion of HSCs on the 2D cultivation.

T-1163

EFFICIENT EXPANSION OF UMBILICAL CORD BLOOD DERIVED CD34$^+$ CELLS IN A CO CULTURE WITH MESENCHYMAL STEM CELLS IN THE PRESENCE OF APOPTOTIC INHIBITORS

Lalita Limaye, Vaijayanti Kale, Darshana Kadekar
National Centre For Cell Science, Pune, India

Umbilical cord blood (UCB) transplantation is an established procedure for the treatment of hematologic, immune, and genetic diseases mainly in pediatric population. An inadequate number of HSCs present in a single UCB unit however limits its use in adults as it may delay engraftment and consequently lead to higher rates of graft failure. One of the strategies to overcome this limitation is the ex vivo expansion of HSCs. The involvement of apoptosis during expansion is well documented and has been accounted for inferior quality of expanded cells. Earlier we have demonstrated the beneficial effect of the apoptotic inhibitors on expansion of HSCs in suspension cultures. In order to recapitulate the apoptotic signaling operative between the stromal cells and HSCs, in the present work, we have attempted to modify this expansion strategy by regulating the apoptosis in HSC MSC co-culture system.
UCB-derived CD34+ cells were isolated and cultured either in suspension cultures or in co-cultures with MSCs derived from human cord tissue viz, cord (CMSCs) and placenta (PMSCs) for 10 days. The cultures comprised of serum-free medium supplemented with 25ng /ml each of SCF, TPO, Flt-3L and IL-6 in presence or absence of the pan-caspase inhibitor zVADfmk (500nM) or calpain-1 inhibitor zLLYfmk (15uM). Cells were harvested and the level of expansion was analyzed by phenotypic characterization and functional assays.
The cells expanded in the co-cultures in the presence of apoptotic inhibitors displayed higher proliferation with significantly more retention of the primitive CD34$^+$CD38$^-$ and CD 133$^+$ cells as compared to suspension cultures as well as control co-cultures. Apoptotic inhibition during co-cultures with MSCs significantly increased the *in vitro* clonogenicity, migratory and adhesion abilities as compared to the suspension cultures. Amongst the feeders we observed a difference in the ability of the CMSCs vs. the PMSCs for the expansion of HSCs. To rule out sample to sample variation we used PMSCs and CMSCs from the same donor. Though there was no significant difference in the morphology and surface marker expression in CMSCs and PMSCs, we observed that co-culture with the PMSCs in presence of apoptotic inhibitors harbored significantly more primitive HSCs with improved in vitro functionality. Thus we conclude that the synergy between MSCs and apoptotic inhibitors facilitate superior *ex vivo* expansion of HSCs. The placental MSCs in presence of apoptotic inhibitors pose a better system for expansion of UCB CD 34+ cells .Therefore our expansion strategy which results in superior quality graft may find direct application in UCB transplantation settings in the clinics.

T-1164

VITAMIN D3 NEGATIVELY REGULATES HEMATOPOIETIC STEM CELL DEVELOPMENT BY AFFECTING VASCULAR NICHE FORMATION THROUGH INHIBITION OF HEDGEHOG SIGNALING

Mauricio Cortes[1], Kelsey Natsuhara[2], Wolfram Goessling[3], Trista E. North[1]
[1]Pathology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, [2]Harvard University, Cambridge, MA, United States, [3]Division of Genetics and Gastroenterology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States

Studies of the vitamin D3 signaling pathway have revealed a broad role for this hormone in tissue homeostasis and as a result there is great interest in exploring the therapeutic potential of vitamin D3 for the treatment of various diseases. While in vitro studies have shown that Vitamin D3 exhibits anti-proliferative and pro-differentiation effects on leukemic cell lines, its role in hematopoietic stem cell (HSC) homeostasis and leukemia progression in vivo is not well understood. To elucidate the mechanisms of action of vitamin D3 in vivo during HSC self-renewal and differentiation we turned to the zebrafish as an animal model due to their evolutionary conserved blood system and their amenability for genetic and chemical manipulation. Vitamin D3 was identified in a chemical as a negative regulator of hematopoiesis in the aorta-gonad mesonephros (AGM), the first site of definitive hematopoiesis. Treatment of zebrafish embryos from early somitogenesis to 36hpf with the non-hydroxylated vitamin D3 precursor cholecalciferol (D3) resulted in decreased mRNA expression of the HSC markers runx1 and c-myb as determined by whole mount in situ hybridization (WISH) and by reduced GFP expression in the AGM of Tg(runx1P2:egfp) zebrafish embryos. To quantify the reduction in HSCs observed by WISH, FACS analysis was performed on double positive Tg(Lmo2:dsRed), Tg(c-myb:gfp) embryos revealing a 25% decrease in the number of double positive cells corresponding to HSC progenitors at 36hpf. To elucidate the mechanism of action of D3 on HSC formation, embryos were treated between 12-24hpf (the period of vascular niche formation) and 24-36hpf (the period of HSC induction and expansion). Treatments with D3 after 24hpf did not have an effect in runx1/c-myb expression. In contrast, exposure of embryos with D3 from 12-24hpf resulted in a decrease in runx1 expression at 36hpf suggesting that D3 is acting during the establishment of the vascular niche. Vascular niche formation is a highly orchestrated process regulated by a cascade of signaling pathways including hedgehog (Hh) signaling. Based on the importance of Hh signaling in artery/vein specification and published in vitro data on the role of D3 in Hh pathway inhibition, we postulated that the negative effect of D3 on HSC formation was mediated through decreased in Hh signaling. In support of our hypothesis, treatment with D3 resulted in decreased Hh signaling as determined by a reduction in ptch2 mRNA expression via WISH, and by reduced Gli reporter activity as measured by FACS using the Tg(6xGLi:mCherry) reporter line. Interestingly co-treatments of zebrafish embryos with the Hg antagonist cyclopamine and D3 resulted in severe inhibition of Hh signaling and loss of runx1 positive cells in the AGM revealing synergy between these two compounds. In addition, co-treatment with the Hh agonist SAG rescued the HSC defect in D3 treated embryos. Hh signaling regulates vein/artery specification through the activation of notch. Consistent with reduction in Hh signaling, D3 treated embryos had a reduction in notch reporter activity and expansion of venous cell fate with concomitant reduction in artery specification. In sum, these studies revealed vitamin D3 acts as negative regulator of HSC formation by inhibiting hedgehog-notch signaling and affecting vascular niche specification.

THE TRANSCRIPTION FACTOR AND EMT MEDIATOR ZEB2 IS AN ESSENTIAL REGULATOR OF DIFFERENTIATION IN ADULT MURINE HEMATOPOIETIC STEM CELLS

Tamara Riedt[1], Steven Goossens[2], Ines Guetgemann[1], Carmen Carrillo Garcia[1], Hichem Gallala[1], Jin Li[1], Holger Froehlich[1], Peter Brossart[1], Danny Huylebroeck[3], Jody Haigh[2], Viktor Janzen[1]
[1]University of Bonn, Bonn, Germany, [2]University Ghent, Ghent, Belgium, [3]University of Leuven, Leuven, Belgium

The life long replenishment of highly specialized blood cells by a small number of hematopoietic cells (HSC) requires a strict regulation between self-renewal and differentiation in the immature compartment of the bone marrow. Perturbation of this equilibrium can result in hematopoietic failure due to maturation defects or development of hematological malignancies. The regulation of self renewal and differentiation processes are mainly controlled by a network of transcription factors. Zeb2 is a transcriptional repressor that plays an important role during embryonic development as a modulator of the epithelial to mesenchymal transition (EMT) and is also associated with tumor progression and metastasis. We have recently reported thatZeb2 is essential for murine embryonic hematopoiesis. The aim of this study was to define the role of Zeb2 in the regulation of homeostasis in the adult hematopoietic system.
Using an inducible Zeb2 knock out mouse model based on the Mx1-Cre promoter we analyzed the impact of Zeb2 loss on adult hematopoietic stem cell function. Upon Zeb2 deletion mice developed severe cytopenia with drastic

reduction in thrombocytes, monocytes, B- and T- lymphocytes and progressive anemia.. However, analysis of the primitive bone marrow compartment revealed that Zeb2 deletion resulted in a pronounced increase in the most immature hematopoietic cells (Lin-Sca1+cKit+CD48-CD150+). In addition, we observed a perturbation in different lineage restricted progenitor subpopulations upon Zeb2 deletion. No difference in cell cycling activity or apoptotic rate in the stem cell enriched bone marrow population was detectable between the genotypes. Transplantation of Zeb2-deficient bone marrow cells into lethally irradiated wild type recipients revealed significantly reduced ability of Zeb2-deficient stem cells to differentiate into multiple hematopoietic lineages. On the other hand, transplantation of WT cells into a Zeb2-deficient microenvironment displayed no obvious maturation defects. These results indicate a niche-independent effect of Zeb2 in promoting differentiation of hematopoietic stem cells.
In addition, conditional Zeb2 knock out animals displayed several features of a myeloproliferative disease resembling the early stages of human primary myelofibrosis, including predominant myeloid proliferation in the bone marrow accompanied with morphological abnormalities in megakaryocytes and reticular fibrosis. Furthermore, Zeb2-deficient mice also displayed progressive extramedullary hematopoiesis in spleen and lymph nodes.
At the molecular level, Zeb2 deficiency resulted in upregulation of numerous genes, as shown by microarray analysis from isolated primitive hematopoietic cells, consistent with its known role as transcriptional repressor. Among those we identified GATA-2 and Id2, both molecules involved in the differentiation process as putative targets of Zeb2.
Our data thus indicate that Zeb2 is involved in the regulation of differentiation at multiple stages of hematopoietic cell maturation. Furthermore, lack of Zeb2 in the hematopoietic compartment leads to a phenotype that resembles the features of early human myeloproliferative disease.

T-1166

THE ROLE OF PRDM16 ISOFORMS IN HEMATOPOIETIC STEM CELL FUNCTION

Larry L. Luchsinger[1], Kenjiro Kamezaki[1], David Corrigan[1], Eric Schon[2], Hans Willem Snoeck[1]
[A]Columbia Center for Translational Immunology, [B]Neurology, [1]Columbia University, New York, NY, United States

Hematopoiesis is the continuous production of differentiated blood cells from hematopoietic stem cells (HSCs) located in bone marrow. HSCs can self renew and are multipotent. However, the mechanisms regulating these properties have not yet emerged. Treatments of disorders such as leukemia, lymphoma and myeloma have been successfully achieved through HSC transplantation. Hence advancing our understanding of HSC biology may improve targeted therapies to treat diseases of HSC origin. Findings by our lab and others have shown the transcription factor PRDI/RIZ1 domain molecule 16 (Prdm16) is specifically required for HSC maintenance and self renewal yet its molecular targets are unknown. Expression of mitochondrial genes, such as the brown adipose-specific thermogenic regulator uncoupling protein 1 (Ucp1), requires *Prdm16*. ***Therefore, we hypothesized that Prdm16 deletion alters mitochondrial function in HSCs.*** To evaluate mitochondria, lineage$^-$/cKit$^+$/Sca$^+$ (LSK) hematopoietic stem progenitor cells (HSPCs) and mouse embryonic fibroblasts (MEFs) stained with Mitotracker Red (MTR) revealed a filamentous network while *Prdm16*$^{-/-}$ cells displayed fragmented and dispersed globular mitochondria which showed defective fusion as observed in mitochondrial fusion assays. Evaluation of mitochondrial morphology in wild type (Wt) hematopoietic cell compartments revealed that HSC mitochondria, and to a lesser extent multiple myeloid progenitor (MPP), were hyperfused compared to differentiated lineages, suggesting a critical role for mitochondrial fusion in primitive hematopoietic cells. Together, these data show HSCs have hyperfused mitochondria and Prdm16 regulation of mitochondrial dynamics is critical for HSC maintenance. Regulation of mitochondrial dynamics relies on a balance in activity of the fission protein dynamin-related protein (Drp1) and the mitofusin (Mfn) family of outer mitochondrial membrane fusion proteins. Therefore, we tested the hypothesis that *Prdm16* regulates *Mfn* expression. *Mfn2*, but not *Mfn1* mRNA levels were decreased >80% in *Prdm16*$^{-/-}$ than in Wt MEFs. Similar data were obtained in using adult *Prdm16*$^{+/-}$ LSK cells. As expected, retroviral Prdm16 restored expression of *Mfn2* to Wt levels in MEFs. Chromatin immunoprecipitation (ChIP) of epitope-tagged Prdm16 constructs showed association of Prdm16 to the *Mfn2* locus in *Prdm16*$^{-/-}$ MEFs. These data suggest *Prdm16* regulates *Mfn2* expression and mitochondrial dynamics. Impaired fusion has been shown to result in abnormal mitochondrial metabolism. Therefore, we measured oxygen

consumption rate (OCR) and extracellular acidification rate (ECAR) which are proportional to the degree of OXPHOS and glycolysis. We found a strikingly lower baseline OCR in *Prdm16*$^{-/-}$. Conversely, ECAR was several folds higher in *Prdm16*$^{-/-}$ than in Wt MEFs, consistent with a >2-fold increase in lactate dehydrogenase (LDH) activity in *Prdm16*$^{-/-}$ MEFs relative to Wt control. These data are consistent with reduced mitochondrial respiration and a compensatory increase in glycolysis, a phenotype also observed in cells where *Mfn2* was knocked down. These data suggest *Prdm16*$^{-/-}$ MEFs have inefficient respiration. In conclusion, we identified *Mfn2* to be a novel target of Prdm16 regulation, the disruption of which alters mitochondrial dynamics. These findings may explain the loss of HSC maintenance and self renewal observed in *Prdm16*$^{-/-}$ HSCs and propose a critical role for mitochondrial dynamics in stem cell function.

T-1167

HEMATOPOIETIC STEM CELL HETEROGENEITY IS MAINTAINED BY DISTINCT ARTERIOLAR PERIVASCULAR AND ENDOSTEAL ZONES

Ryohichi Sugimura, Xi C. He, Aparna Venkatraman, John M. Perry, Linheng Li
Stowers Institute, Kansas City, MO, United States

Heterogeneity in either hematopoietic stem cells (HSCs) or their associated niches has been recognized in recent years; however, the relationship between the two and related properties remains largely unexplored. We attempted to characterize the function, location and metabolism of deeply quiescent HSCs and less quiescent HSCs. To determine cell-cycle frequency of such populations, we used CD49b, which is able to distinguish long-term (LT)-HSCs from intermediate-term (IT)-HSCs, to separate CD34^{-}Flk2^{-}LSK HSCs. We found that CD49b^{lo} HSCs enter into cell-cycle 1/100-120 days, while CD49b^{hi} HSCs do so 1/25-30 days according to H2B-GFP label regression assay. In the competitive reconstitution assay, CD49b^{lo} HSCs supported multipotent hematopoiesis for life-long (80% donor engraftment), while CD49b^{hi} HSCs supported hematopoiesis with 20% donor-engraftment and lost red blood cells and myeloid lineage by 20 weeks. CD49b^{lo} HSCs survived 5-fluorouracil (5FU) stress and underwent subsequent expansion to replenish CD49b^{hi} HSCs that were sensitive to 5FU and lost post treatment. Therefore, we demonstrated that CD49b^{lo} HSCs were deeply quiescent and functioned as a reserve population, while CD49b^{hi} HSCs were less quiescent and primed for action (primed HSCs). We then found that CD49b^{lo} reserve HSCs were enriched in the endosteal zone of the trabecular bone region, while CD49b^{hi} primed HSCs were enriched in the arteriolar (Tie2^{+}) perivascular zone. Furthermore, reserve and primed HSCs preferentially underwent anaerobic (p-PDH^{+} indicating glycolysis) and aerobic (Cox4-1^{+} indicating mitochondria-dependent) metabolism, respectively. This differential metabolic pathway was consistent with their hypoxic (GRP78^{+}) or hyperoxic microenvironment. We previously reported that deeply quiescent HSCs were maintained by noncanonical Wnt signaling through Frizzled (Fz) 8 in the endosteal zone (Sugimura *et al*., 2012. *Cell*). Now we show that another noncanonical Wnt receptor Fz5 maintains primed HSCs in the Fz5^{+}Nestin-GFP^{+}alpha-smooth muscle actin (αSMA)$^{+}$ cells in the arteriolar perivascular zone. Mechanistically, Fz5 regulates planar cell polarity (PCP) pathway and determines the polarity of the Cdc42-CXCR4 complex in primed HSCs. Thus CXCR4 engages with membrane-bound SDF1 in adjacent CXCL12-abundant reticular (CAR) cells. Loss of Fz5 results in random distribution of CXCR4 in primed HSCs and leads to HSC migration to the sinusoidal zone_leading to increased cell cycling coupled with loss of functional capacity. Thus, we establish the distinction between primed and reserve HSCs based on niche location, metabolism, signaling pathway regulation, and functional capacity.

ELUCIDATION OF NOVEL GENETIC REGULATORS OF HEMATOPOIETIC STEM CELL DEVELOPMENT USING A ZEBRAFISH FORWARD GENETIC SCREEN

Julie R. Perlin[1], Logan Carr[1], Carolyn Wise[1], Weijun Pan[2], Leonard Zon[1]
[1]Hematology Oncology, Children's Hospital, Boston, Boston, MA, United States, [2]Institute of Health Sciences, Shanghai Institute of Life Sciences, Shanghai, China

Marrow transplantation of hematopoietic stem cells (HSCs) is an important therapy for patients with a variety of anemias, immunodeficiencies, and leukemias. The transplant relies on the homing and engraftment of donor HSCs to the recipient marrow, yet the genetics of such cell mobility are not understood. In development, HSCs arise from the aorta, enter circulation, and then undergo dynamic interactions with associated endothelial cells to form the blood stem cell niche. We have undertaken the first large-scale genetic screen to uncover pathways essential for HSC engraftment into the stem cell niche in the zebrafish. Over 50 mutants were found that were morphologically normal, but that had specific alterations in the expression of cmyb, a critical hematopoietic transcription factor, in the fetal liver equivalent of the zebrafish, or caudal hematopoietic tissue (CHT). cmyb is a conserved transcription factor expressed in hematopoietic progenitors, which is required for hematopoietic progenitor specification, maintenance, and differentiation. 5 mutant lines have been identified with a reduction of hematopoietic stem cells (HSCs) by reduced cmyb in the CHT. In order to determine whether this reduction is due to a lack of HSC production or a failure of HSCs to migrate towards and engraft into the niche, early hematopoietic progenitors were assayed by runx1 in situ hybridization. Mutants that produce HSCs that fail to engraft into the hematopoietic niche were prioritized for further study. We have developed a transgenic line that specifically labels HSCs and that allows for the first visualization of HSC-endothelial cell dynamics required for niche formation. Transgenic lines specifically labeling HSCs and endothelial cells have enabled us to observe engraftment defects in mutant embryos. These studies will provide insight into HSC development and hematopoietic niche formation, and the genes and pathways uncovered may be able to be manipulated to augment therapeutic marrow transplantation.

T-1171

NOVEL NANO-SCALE PHOSPHOPROTEOMIC IDENTIFICATION OF HEMATOPOIETIC PROGENITOR CELL MOBILIZATION PATHWAYS AND LEUKEMIA STEM CELL TARGETS

Leo Wang[1], Scott Ficarro[2], Jessica Sullivan[3], Amy Wagers[4]
[1]Dana-Farber/Children's Hospital Cancer Center, Harvard Stem Cell Institute, Boston, MA, United States, [2]Blais Proteomics Center, Dana-Farber Cancer Institute, Boston, MA, United States, [A]Joslin Diabetes Center, Harvard Stem Cell Institute, [B]Howard Hughes Medical Institute and Joslin Diabetes Center, Harvard Stem Cell Institute, [3]Harvard University, Boston, MA, United States

AML treatment often fails, in part because of the persistence of a small population of leukemia stem cells (LSCs) that are able to propagate disease but are resistant to standard chemotherapy. In order to target LSCs specifically, it is essential to identify pathways that are activated in LSCs but not in their nonmalignant counterparts, hematopoietic stem and progenitor cells (HSPCs). Pharmacologic mobilization of HSPCs mimics some of the characteristics of LSCs, including proliferation and migration. Importantly, however, mobilized HSPCs (mobHSPCs) retain their dependence on growth and stimulatory factors for maintenance; withdrawal of the mobilizing agent causes a swift contraction of the mobHSPC pool. Thus comparison of the resting bone marrow HSPC (bmHSPC) pool with the mobHSPC pool and with LSCs promises to identify unique pathways responsible both for blood cell mobilization and for leukemic transformation. This type of comparison has been performed at a transcriptional level and has yielded important findings, but cellular functions are ultimately effected by proteins. Additionally, mRNA abundance correlates poorly with levels of corresponding proteins and is insensitive to changes in functional activity of those proteins. Analysis of proteins themselves, therefore, is expected to yield critical insights that are not achievable through transcriptional analyses alone.
Only recently have methods been described that allow for detection of robust phosphoproteomes from small numbers of cells, enabling analysis of rare cell populations like HSPCs, which constitute only 0.01-0.1% of all bone marrow hematopoietic cells. Using flow cytometry, stable-isotope labeling, and a novel multidimensional nanoscale phosphoproteomic platform, we have successfully compared the phosphoproteomes of rigorously defined

bmHSPCs, mobHSPCs, and AML LSCs isolated by flow cytometry. Analysis of as few as $2x10^5$ flow-sorted cells by 3D RP-SAX-RP-MS/MS coupled to an Orbitrap Velos mass spectrometer resulted in detection of more than 3,600 unique phosphopeptide sequences. Hierarchical clustering and pathway analysis generated priority lists of candidate proteins more phosphorylated in the resting state (QuiCan), of mobilized state (MobCan) and malignant state (MalCan). Some of these, such as ribosomal protein S6 and PKCθ**,** have previously been described in the literature as important for hematopoietic progenitor function and mobilization. However, many novel candidates were also identified; the first of these has been validated using flow cytometry and protein biochemistry, and its role is being investigated *in vivo*.
We have developed a nanoscale phosphoproteomics platform able to analyze at high resolution small numbers of rare but biologically important cells. This technology has identified many proteins that are activated in HSPC mobilization, and many that are activated in leukemic transformation. Some of these candidates have already been validated, and more are undergoing validation. Further experiments will identify which of these pathways will be most attractive as a target for clinical therapies.

T-1172

ADENOSINE SIGNALING PROMOTES HEMATOPOIETIC STEM CELL PRODUCTION AND MIGRATION DURING ZEBRAFISH HEMATOPOIESIS

Lili Jing, Owen Tamplin, Ellen Durand, Margot Brandt, Leonard I. Zon
Hema/Oncology, Children's Hospital Boston, Boston, MA, United States

During embryogenesis, hematopoietic stem cells (HSCs) first emerge from hemogenic endothelium in the aorta-gonad-mesonephros (AGM) region, and then colonize the fetal liver and ultimately the bone marrow. The signaling pathways that regulate HSC development at different hematopoietic sites remain incompletely characterized. In zebrafish, the caudal hematopoietic tissue (CHT) is the functional equivalent of the mammalian fetal liver. The AGM-derived HSCs first seed at the CHT, expand and then migrate to the thymus and the pronephric kidney. To identify new modulators that directly enhance HSCs in the CHT, we performed a chemical genetic screen in which the embryos were exposed to individual compound from 48 hours post fertilization (hpf) to 72 hpf, and we identified that the adenosine pathway (including exogenous agonists and compounds that inhibit adenosine degradation) increased runx1/cmyb expression at the CHT. Using a hematopoietic stem/progenitor cell (HSPC) reporter line, we confirmed that the adenosine pathway increases the number of HSPCs that colonize the CHT. To examine if adenosine also expands HSCs at the AGM, we treated embryos with adenosine chemicals at an earlier time period (3-somite to 36 hpf) and found that adenosine also increased runx1/cmyb expression at the AGM. The effect was confirmed with adenosine receptor antagonists that decreased runx1/cmyb expression. Among the different adenosine receptors, the adenosine receptor A2B is expressed in endothelial cells in dorsal aorta and caudal vasculature. Knockdown of A2B strongly reduces HSPCs at AGM and CHT without affecting cardiovascular development and circulation. A panel of definitive linage specific markers are reduced in A2B knockdown embryos, supporting that adenosine pathway regulates functional HSPCs. Loss of A2B blocked the effect of adenosine on induction of HSPCs. Together, these data suggest that the adenosine pathway, acting through the A2B receptor, promotes HSC formation during development.

T-1173

TRACKING INDIVIDUAL HEMATOPOIETIC STEM CELL CLONES IN HUMANS BY RETROVIRAL TAGGING

Luca Biasco[1], Serena Scala[1], Cristina Baricordi[1], Francesca Dionisio[1], Andrea Calabria[1], Clelia Di Serio[2], Jason Gardner[3], Christof Von Kalle[4], Manfred Schmidt[4], Chiara Bonini[5], Luigi Naldini[1], Eugenio Montini[1], Alessandro Aiuti[1]
[1]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milan, Italy, [2]CUSSB, Università Vita-Salute San Raffaele, Milan, Italy, [3]GSK R&D, King of Prussia, PA, United States, [4]National Center for Tumor Diseases (NCT-DKFZ), Heidelberg, Germany, [5]San Raffaele Scientific Institute, HSR, Milan, Italy

Understanding how hematopoietic stem cells (HSC) generate and maintain an adequate pool of blood cells throughout human life is extremely relevant for the treatment of hematological disorders. However, information on HSC currently derives from in vitro assays or animal models but not from the direct tracking in humans of individual HSC clones. Upon retroviral gene transfer, transduced cells are univocally marked by vector integration sites (IS). Gene therapy (GT) clinical trials for ADA (adenosine deaminase) deficient-SCID and Wiskott-Aldrich Syndrome (WAS) based on the infusion of genetically engineered HSC, generate an hematopoietic system where vector-marked progenitors and blood cell progeny are traceable in vivo by IS analysis. This unique setting allows studying HSC dynamics at clonal level for the first time directly in humans. To this purpose we collected 32.363 IS from 3 WAS patients treated with lentiviral vector GT up to 1.5 years and 4.845 IS from 4 ADA-SCID patients treated with gammaretroviral (RV) GT up to 6 years after treatment. In WAS GT patients, by the measurement of clonal abundance through sequencing reads, we found an increase in the Shannon Diversity Index of clonal repertoires during the first year after GT. Self-limiting waves of hematopoietic output from transduced HSC were detected early after transplant, stabilizing at 12-18 months after GT. No aberrant clonal expansion was observed. Multipotent HSC could be tracked overtime by detecting identical IS in HSC/colony forming units and mature cells. Of note, we found the highest proportion of shared IS (38.5%) in BM clonogenic progenitors, an important validation of IS analysis consistency and of the colony assay as representative of in vivo HSC activity. Importantly, by mathematical estimators, we calculated a theoretical minimal number of about 7,500 transduced active stem cells corresponding to about 1 in 3x10e5 infused CD34+ cells. In ADA-SCID patients treated with RV-GT we showed that identical IS are consistently detected at multiple lineages level several years after GT. Since RV transduction occurs only in actively replicating cells, this finding provides the first evidence that in vitro stimulated HSC can retain long-term activity in humans. By semi-quantitative PCRs on specific vector-genome junctions we tracked the dynamics and activity of specific HSC clones in these patients, showing a fluctuating but consistent output of marked HSC over a period of 5 years. Notably, we were also able to apply network-based statistical approaches to test the validity of the different proposed models of hematopoietic hierarchy through IS similarity among lineages.
We also analyzed IS in T cell subtypes from ADA-SCID patients who received infusions of gene-corrected mature lymphocytes. Strikingly, we found that transduced T cells with an apparent naïve phenotype retained their plasticity, as they share the highest number of IS with other T subpopulations, while still surviving in vivo 10 years after infusion. These studies allowed us to track the fate of recently defined T memory stem cells (TSCM) carrying naïve plasticity and memory survival. In summary, our IS studies allow defining crucial stem cell properties in vivo in humans providing new information with profound impact on the design of therapeutic strategies for hematological diseases and tumors.

T-1174

RETINOIC ACID SIGNALING INHIBITION DURING HUMAN PLURIPOTENT STEM CELL DIFFERENTIATION PROMOTES HEMOGENIC MESODERM SPECIFICATION AND HEMATOPOIETIC STEM/PROGENITOR CELL MAINTENANCE

Roger Rönn[1], Carolina Guibentif[1], Roksana Moraghebi[1], Patricia C. Guerrero[2], Bradley Garcia[3], Ewa Sitnicka[2], Niels-Bjarne Woods[1]

[A]Gene Therapy and Molecular Medicine, [B]Hematopoietic Stem Cell Laboratory, [1]Lund University, Lund, Sweden, [2]Primorigen Biosciences, Madison, WI, United States

Hematopoietic stem and progenitor cells generated from patient derived induced pluripotent stem (iPS) cells could provide an unlimited supply of HLA matched transplantable cells for the treatment of both hematological disorders and malignancies. Retinoic acid (RA) is a key morphogen involved in the establishment of various cell-fates in the growing embryo. The establishment of certain tissues, including mesodermal derivates such as the somites, heart, and blood depends on restricted exposure to RA during embryonic development. By using an inhibitor of cellular RA synthesis together with our iPS-to-blood differentiation system we report enhanced generation of human hematopoietic progenitors cells (CD45/43+CD34+), and cells with an adult hematopoietic stem cell phenotype (CD45/43+CD34+CD38-CD90+CD45RA-), with myeloid and lymphoid differentiation capacity. RA inhibition increased the output of cells possessing an adult HSC surface phenotype by 2.7-fold (p-value: 0,006, n=6) com-

pared to DMSO control, and increased the number of clonogenic progenitors (CFUs) by 2-fold (p-value: 0,022, n=6). This improvement is consistent when using both a human ES line (Hues3) and a human iPS-line (RB9-CB1, generated from cord blood). Conversely, and in support of our findings, directly adding RA was found to severely decrease the blood generation efficiency of our protocol, with the more primitive progenitor fraction (CD45/43+CD34+CD38-CD90+CD45RA-) significantly decreased even at lower concentrations of RA. When comparing the colony forming potential of sorted hematopoietic progenitors, RA inhibition enabled the generation of CFU-forming cells at efficiencies directly comparable to that of CB, with colony counts being significantly higher per sorted progenitor than the DMSO control, thus suggesting increased preservation of functional CFU-forming cells. RA inhibition increased the number of iPS-derived CD45/43+CD34+ cells capable of differentiation into the lymphoid lineage, generating phenotypic T-, B-, and NK-cells after sub-culture on OP9 stroma. The observed increase in more primitive hematopoietic progenitors (CD45/43+CD34+CD38-CD90+CD45RA-) without any significant increase in the total number of blood cells (CD45/43+) suggest that RA inhibition act to maintain the more primitive progenitor fraction. However, RT-qPCR analysis of key developmental genes during the differentiation process revealed improved commitment and differentiation of the pluripotent stem cells towards hematopoietic mesoderm at several distinct developmental stages including increased generation of mesoderm (BRACHYURY), decreased amounts of later cardiogenic mesoderm (NKX2.5), and enhanced expression levels of genes known to be relevant for definitive hematopoiesis and hemogenic endothelium (RUNX1, FLK1, APLNR, PDGFRa). Together, these findings indicate that inhibition of RA signaling act to both enhance the developmental commitment towards hematopoietic mesoderm, and to improve the maintenance of newly emerged blood cells. We propose that control over RA signaling can, in addition to the already established roles of other key factors and cytokines, allow for better developmental specification towards various cell lineages in the in vitro setting.

INTEGRIN BETA3 BIDIRECTIONALLY REGULATES LONG-TERM REPOPULATING ACTIVITY IN MURINE HEMATOPOIETIC STEM CELLS

Terumasa Umemoto[1], Yoshiko Shiratsuchi[1], Jun Ishihara[1], Sung-Joon Park[2], Kenta Nakai[2], Masayuki Yamato[1], Teruo Okano[1]

[1]Institute of Advanced Biomedical Enginerring and Science, Tokyo Women's Medical University, Tokyo, Japan, [2]Human genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Hematopoietic stem cells (HSCs) reside in a specialized microenvironment or “niche” within the bone marrow (BM), where their self-renewal, differentiation, and quiescence are regulated. We previously demonstrated that integrin αvβ3 (CD51/CD61) is highly expressed in murine CD34-KSL HSCs (CD34- c-Kit+ Sca-1+ Lin-), but not in CD34+KSL HSCs (Umemoto et al., J. Immunol, 2006). Further, integrin β3 signaling contributes to the maintenance of the long-term repopulating (LTR) activity of HSCs in vivo and in vitro, which is dependent on the presence of thrombopoietin (TPO) (Umemoto et al., Blood, 2012). Although our previous finding has suggested that integrin β3 functions as a positive regulator of HSC activity in the BM niche, in this study, we demonstrate a novel role of integrin αvβ3 in the regulation of HSCs.

Recently, we detected that triiodothyronine (T3), a thyroid hormone, could suppress the LTR activity of HSCs by means of transplantation assays using HSCs cultured in the presence or absence of T3. Interestingly, this negative effect of T3 is enhanced by specific ligation of integrin β3 via the extracellular matrix protein, even in the presence of TPO. In addition, integrin β3 signaling had little influence on HSC number when cultured in the presence of T3. These results indicate that T3 reverses the previously reported positive effect of integrin β3 on the LTR activity of HSCs and that integrin β3 signaling preferentially contributes to enhance the negative effect of T3 rather than to maintain LTR activity by collaborating with TPO. To clarify the influence of T3 on HSCs, we compared the gene expression profiles of untreated and T3-treated HSC globally by using mRNA sequences, and then carried out statistical analyses focused on transcription factor binding motifs within the promoter regions of the genes. The expression level of some of the analyzed genes is changed by T3 treatment, suggesting that T3 contributes to the enhancement of STAT1-dependent gene expression in HSCs. Excess activation of STAT1 reportedly diminishes LTR

activity of HSCs. In addition, we also confirmed that IFNγ, an activator of STAT1, showed the negative influence on the maintenance of LTR activity in HSCs. Moreover, this suppressive effect of IFNγ on LTR activity was also enhanced by integrin β3 signaling, similar to that of T3. These data suggest that STAT1 is involved in the T3-mediated reversal of integrin function.
Collectively, our results indicate that integrin β3 signaling in HSCs contributes to the suppression of the LTR activity of HSCs in the presence of T3 or IFNγ, possibly through STAT1-dependent control of gene expression. Thus, given our previous report that integrin β3 signaling in HSCs exerts the positive effect on LTR activity by collaborating with TPO, integrin αvβ3 on HSCs seems to be involved in the bidirectional regulation of their LTR activity in response to surrounding environments. Further, integrin αvβ3 may play a key role in the regulation of HSC functions and/or maintaining the stemness within the BM niche.

T-1176

DEFINING THE MOLECULAR BASIS FOR REVERSIBLE SUPPRESSION OF HEMATOPOIETIC STEM CELLS IN LEUKEMIC MARROW

Hui Cheng, Yanfeng Liu, Yakun Pang, Sha Hao, Shihui Ma, Yingxu Shi, Jing Xu, Jinhong Wang, Guoguang Zheng, Weiping Yuan, Tao Cheng
Institute of Hematology, Tianjin, China

The response of hematopoietic stem cells (HSCs) and hematopoietic progenitor cells (HPCs) to stress or disease conditions has been gaining increased attention in recent years. Our previous study demonstrated that HSCs/HPCs were reversibly suppressed in an irradiated acute T lymphoblastic leukemia (T-ALL) mouse model (Hu X et al, *Blood 2009*). This current work aims to further examine the kinetics of normal HSCs and HPCs in acute myeloid leukemia (AML) and to define a common molecular basis of suppressed HSCs in AML and ALL.
To this end, we first established an AML model using the human MLL-AF9 fusion gene in non-irradiated mouse recipients. Normal hematopoiesis was progressively suppressed during leukemia development in this model, with the leukemic environment imposing different effects on LKS^+ HSCs and LKS^- HPCs in the bone marrow (BM). The frequency of normal LKS^- HPCs in the leukemic BM increased modestly and then was exhausted during leukemogenesis whereas the frequency of normal LKS^+ or $LKS^+CD34^-Flk2^-$ cells progressively increased from day 7 to day 21. The absolute numbers of both HSCs and HPCs in the BM decreased during leukemia development. In contrast, the frequencies and absolute numbers of HSCs and HPCs in the leukemic spleen increased from day 7 to day 14, and then dropped to normal levels at day 21. Cell cycle status was further assessed. More HSCs and HPCs were accumulated in the G0 phase in leukemic BM during leukemia development and as a result, LKS^+ or LKS^+CD34^- HSCs in the late stage of leukemia were kept in a nearly non-proliferative status. Interestingly however, HPCs had an increased proliferative rate and HSCs showed a normal cell cycle profile in the leukemic spleen. In accordance with the increased frequency of primitive cells, the normal $CD45.1^+$ cell population from leukemic BM had a significantly higher long-term engraftment capacity than that from normal BM at day 14. However, no significant difference was observed in the competitive repopulation assay when the long-term repopulating HSCs were transplanted, indicating equal reconstitution potential of the HSCs (average function per HSC) from leukemia versus control mice. Furthermore, we also sorted the $CD45.1^+LKS^+$ population from control or leukemia mice at different time points for the gene expression profiling analysis. Three genes (Maff, Hey1, Egr3) were selected for a series of functional validations. Using the zebrafish knock-down assay, we found that all three genes seemed to be required for definitive hematopoiesis. Upon forced expression of these genes in mouse HSCs by retroviral transduction, Egr3 restricted the proliferation of HSCs likely via up-regulation of the CDK inhibitors, p18 and p19, whereas Maff and Hey1 were able to enhance the function of HSCs, thus suggesting that these genes play distinct roles in inhibiting or protecting HSCs during the expansion of leukemic cell populations.
In summary, our current study reveals a molecular basis for the reversible suppression of normal HSCs during the expansion of leukemic cells in the BM, thereby having implications for the development of new therapeutic strategies for leukemia.

T-1177

PTEN LOSS IN THE BONE MARROW LEADS TO GCSF MEDIATED HSC MOBILIZATION.

Melania Tesio[1], Gabriela Oser[1], Irene Baccelli[1], Hong Wu[2], Joachim R. Göthert[3], Scott C. Kogan[4], Andreas Trumpp[1]
[1]German Cancer Research Center, Heidelberg, Heidelberg, Germany, [2]Eli and Edythe Broad Center of Regenerative Medicine and Stem Cell Research, Los Angeles, CA, United States, [3]University Duisburg-Essen, Essen, Germany, [4]USCF Medical Center, San Francisco, CA, United States

The phosphatase and tumor suppressor PTEN inhibits the phosphoinositol-3-kinase (PI3K) signaling pathway and plays a key role in cell growth, proliferation, survival and migration. Pten conditional deletion using MxCre or Scl-CreERT2 leads to splenomegaly and leukemia formation, which occurs after the re-location of normal HSCs from the bone marrow to the spleen. Unexpectedly, dormant HSCs in the bone marrow do not enter the cell cycle upon PTEN loss nor do they lose self-renewal activity or are exhausted. Instead, Pten deficiency causes an up-regulation of the PI3K pathway in myeloid cells, but not in HSCs. Strikingly, myeloid cells secrete high levels of G-CSF upon Pten loss leading to the mobilization of HSCs from the bone marrow and accumulation in the spleen. Following deletion of Pten in mice lacking G-CSF the splenomegaly, myeloproliferative disease and splenic HSCs accumulation are rescued. Our data show that while PTEN has little if any role in HSCs, it is essential to prevent overt G-CSF production by myeloid and stromal cells which otherwise causes HSCs to re-locate to the spleen followed by lethal leukemia initiation.

T-1178

EXPANSION AND ORDERLY DIFFERENTIATION OF MEGAKARYOCYTIC PROGENITOR CELLS GENERATED FROM CORD BLOOD HEMATOPOIETIC STEM/PROGENITOR CELLS AND ITS PHASE I/II CLINICAL TRIALS

Xuetao Pei
Inst of Transfusion Medicine. Academy of Military Medical Sciences, Beijing, China

Thrombocytopenia is a common and potentially fatal complication of high-dose chemotherapy and hematopoietic stem cell transplantation. Infusion of platelets from unrelated donors is currently the only effective treatment to prevent fatal hemorrhage. Hematopoietic stem cells (HSCs) from bone marrow (BM), cord blood (CB), and peripheral blood (PB) can be used to generate functional hematopoietic progenitor cells, including megakaryocytic progenitors (MPs), megakaryocytes, and platelets. Umbilical cord blood is an abundant source of HSCs. Cord blood is also highly enriched in committed hematopoietic progenitor cells, including those of the megakaryocytic lineage. In vitro large scale production of hematopoietic progenitor cells from cord blood could represent an effective blood cell substitute. In the present study, our objective was to determine the safety and feasibility of ex vivo generated hematopoietic progenitor cells (HPCs) in patients with hematological malignancy. Based on promising results of our preclinical study, state food and drug administration (SFDA) of China approved our group to conduct a clinical trial of HPCs injection to patients with hematologic malignancy. We investigated the feasibility of large-scale expansion, orderly differentiation and infusion of cord blood-derived HPCs in the patients with advanced hematological malignancyes. No adverse effects were observed in patients who received ex vivo-generated cells. Further, a moderate effect on platelet recovery was also observed. Administration of cord blood-derived HPCs appeared safe and feasible for treatment of thrombocytopenia after chemotherapy.

T-1181

EFFECT OF MESENCHYMAL STEM CELL TO SUPPORT GAMMA IRRADIATED HUMAN UMBILICAL CORD BLOOD CD133+ CELLS

Roya Rafiee[1], Marzieh Ebrahimi[2], Nasser Aghdami[3], Hamid Gourabi[1]
[A]Genetics, [B]Cancer and Hematopoietic Stem Cells, [C]Regenerative Medicine, [1]Royan Institute, Tehran, Iran, Islamic Republic of

The recovery of organs and tissues after irradiation process are usually depend on resident stem cells re-population in target organ. Hematopoetic Stem Cells (HSCs) and Mesenchymal Stem Cells (MSCs) constitute two major stem cells populations in bone marrow with more primitive phenotype sub-population of bone marrow mononuclear cells and adherent fibroblast-like cells, respectively. Interaction of these two populations have significant role in maintaining and reconstruction of hematopoesis system.Umbilical cord-derived stromal cells were applied in order to recovery of irradiated CD133+ which derived from human umbilical cord-blood in a serum-free liquid culture supplemented with combination of stem cell factor, thrombopoietin and Flt-3. Post irradiation analysis were performed for human irradiated and non-irradiated CD133+ cells at the day of experiment and also seven days after irradiation in presence/absence of MSCs. Lymphoid and myeloid-erythroid lineage markers (CD33, CD19), expression of adhesion molecule (CXCR4), HSCs markers (CD133, CD34 and CD133/34), and DNA breaks were analyzed by flowcytometry technique. The colony-forming cells were assessed by methylcellulose culturing method using MethoCult. Expansion rate of cells were evaluated by cell counting.
Our results demonstrated that MSCs can support expansion of human irradiated CD133+ with ratio of 1.92 fold. Their colony-forming potential was 2.12 fold with an increasing ratio to 2.14 fold in Granolocyte-Macrophage colonies (GM) and 1.6 fold in MIX colonies (GM-BFU). Presence of MSCs was caused shifting to myeloid-erythroid lineage with expression of CD33 (19.7 ± 12%). Co-cultured of human irradiated CD133+ with MSCs were shown the expression of CD 133 (5.36 ± 1.57%), CD34 (2.5 ± 0.75%) and CD133/34 (1.5 ± 0.5%). Interestingly, DNA breaks repair was increased to 7.5 folds co-cultured with MSCs. Expression of CXCR4 did not reveal a significant expression in both groups.
Direct contact of human irradiated CD133+ with MSCs preserve not only the expansion, and function of human irradiated CD133+ cells, but also shifting towards to mylo-erythroid lineage. MSCs promotes recruitment of DNA repair system and deletion of free-radical which resulted from ionizing radiation.

T-1182

OSTEOBLAST ABLATION FROM THE BONE MARROW ENHANCES SHORT-TERM HEMATOPOIETIC STEM CELLS WITHOUT ALTERING LONG-TERM SELF-RENEWING HEMATOPOIETIC STEM CELL POPULATIONS

Marisa Bowers, Ho Yin-Wei, Ravi Bhatia
Beckman Research Institute, City of Hope, Duarte, CA, United States

The bone marrow (BM) microenvironment plays a critical role in supporting and regulating normal hematopoiesis. Hematopoietic stem cells (HSCs) are reported to reside in proximity to endosteal osteoblasts (OBs) in the BM, and OBs are hypothesized to provide a HSC niche. However, other studies suggest that perivascular mesenchymal cells or endothelial cells provide HSC niches, and the specific role of OBs in maintaining HSCs is not well understood. We use a conditional OB ablation mouse model (Col2.3Δtk) to examine the role of OBs in hematopoiesis and HSC function. In this model a truncated version of herpes simplex virus thymidine kinase (Δtk) is specifically expressed in OB. Daily intraperitoneal (IP) administration of ganciclovir (GCV) leads to interaction with Δtk, producing a toxic DNA base analogue that results in specific killing of OBs. To facilitate tracking of OB ablation, we crossed the Col2.3Δtk mice with Col2.3GFP mice that specifically express GFP in OBs. Through immunofluorescent, immnunohistochemical and flow cytometry analysis, we confirmed GCV administration ablated endosteal OBs in our model system. OB ablation resulted in a decrease in overall BM cellularity (Δtk+ 3.7e7±3.0e6, Δtk- 4.8e7±3.8e6, p=0.04), but did not alter cellularity of the spleen (SP) (Δtk+ 5.1e7±5.3e6, Δtk- 6.3e7±7.4e6, p=0.19). Flow cytometric analysis of hematopoietic populations showed that OB ablation significantly increased phenotypic long-term HSC (LT-HSC) populations (Lin-Kit+Sca-1+Flt3-CD150+CD48-) in both the BM (cell number: Δtk+ 6490±1315, Δtk- 4236±922; percentage: Δtk+ 0.017%±0.003, Δtk- 0.009%±0.002; p=0.03) and SP (cell number: Δtk+ 980±473, Δtk- 96±40; percentage: Δtk+ 0.002%±0.0001, Δtk- 0.0002%±0.001; p=0.04). OB ablation also leads to significant increases in common myeloid progenitor (CMP) (cell number: Δtk+ 145114±43608, Δtk- 82200±26754; percentage: Δtk+ 0.26%±0.056, Δtk- 0.11%±0.021; p=0.002) and granulocyte/monocyte progenitor (GMP) (cell number: Δtk+ 51411±17349, Δtk- 20206±9279, p=0.003; percentage: Δtk+ 0.09%±0.03, Δtk- 0.31%±0.01, p=0.02) populations in the SP, but does not alter other hematopoietic populations in BM, SP or PB. To determine the stem cell potential of phenotypically defined LT-HSCs in our model we performed limiting-dilution competitive repopulation assays. LT-HSCs from OB ab-

lated mice demonstrated a higher frequency of short-term repopulating cells (5 and 10 weeks) compared to LT-HSC from non-ablated mice (5 weeks Δtk+:Δtk-=3.51, 10 weeks Δtk+:Δtk-=4.99) but similar long-term engraftment (15 weeks; Δtk+:Δtk-=1.01). Transplantation of BM cells from primary transplant recipients into secondary recipients demonstrated that LT-HSCs from OB ablated mice have similar long-term engraftment potential to those from non-ablated mice after second transplant. These results suggest that the increased numbers of phenotypic LT-HSCs in OB ablated mice may represent the expansion of a HSC pool with short-term repopulating capacity, but that HSCs with long-term repopulating and self-renewing capacity remain unchanged in OB ablated mice. Collectively, these studies indicate that OB are not an essential niche component for long-term repopulating, self-renewing HSCs, but may restrict generation and/or expansion of short-term HSCs within the BM.

School of Med., Tokyo, Japan, [3]Medicine, Case Western Reserve University, Cleveland, IL, United States, [4]Vascular Regeneration Research Group, Institute of Biomedical Research and Innovation, Kobe, Japan

BACKGROUND: Apheresed cell therapy for vascular regeneration targeting ischemic diseases using peripheral blood (PB) mononuclear cells (MNCs) or PBCD34+ cells underwent G-CSF administration, has been clinically developed. Here, we tried to investigate the therapeutic potential of MNCs isolated from intravenously aspirated PB, operated the recently developed serum-free culture (SFC) of stem cell fraction for augmentation of vascular regeneration.
METHODS and RESULTS: SFC were performed for PBMNCs isolated from the healthy human subjects (N= 18), using StemLine II containing SCF, TPO, Flt-3 ligand, VEGF and IL-6 for 7 days. EPC- colony forming assay unveiled the outstanding expansion of vasculogenic definitve colony forming cells in SFC cells at 42 fold in the equivalent cell No. of PBMNCs and 19 fold per original 100 ml PB. Moreover, flow cytometry of SFC cells disclosed the anti-inflammatory macrophage polarization of M1 (CCR2+ cell) to M2 (CD206+ cell) at 2.1 x10-3 fold of PBMNCs in M1/M2 ratio.
In real time qPCR, the gene expression of growth factors/cytokines in SFC cells was predominantly upregulated (fold increase = 4.2 or 2.4 for VEGF-B or angiopoietin-1; 35.9, 6.3 or 5.4 for Leptin, IL-8 or IL-10), inversely that of IL-1β or TGF- β downregulated (fold decrease = 0.23 or 0.44 for IL-1β or TGF- β).
Laser doppler analysis at day 20 post the intramuscular cell transplanattion (Tx) (1 x104 cells /mouse= equivalent to the cell No. acquired from less than 100 ml human PB) at the next day of ischemic surgery presented that SFC cell-Tx significantly recovered the blood flow ratio of ischemic/healthy hindlimb at 1.8 fold vs PBMNC-Tx, where the ratio was equivalent to non cell-Tx (N= 12). The assessment of ischemic hindlimb disclosed that SFC cell-Tx increased isolectin B4-FITC+ capillary density at 3.4 fold vs PBMNC-Tx. Further, the recruitment of α SM actin+ pericytes in SFC cell-Tx was also predominantly detected at 2.0 fold vs PBMNC-Tx.
CONCLUSION: SFC potentiates the vascular regeneration ability of naïve PBMNCs isolated under venous aspiration via the orchestration of promoted effects for arteriogenesis, anti-inflammation, as well as angiogenesis, thereby providing a practical therapeutic application for ischemic diseases.

WNT/β-CATENIN AND MTOR SIGNALING REGULATE MAINTENANCE OF HUMAN AND MOUSE HEMATOPOIETIC STEM CELLS

Michelle Nguyen-McCarty, Jian Huang, Peter Klein
University of Pennsylvania, Philadelphia, PA, United States

Hematopoietic stem cells (HSCs) possess the dual capacities to self-renew and to differentiate into all blood cells. The molecular signals regulating HSC homeostasis are incompletely understood. We thus aimed to define regulators of HSC maintenance. We have found that knockdown of *glycogen synthase kinase-3* (*Gsk-3*) in bone marrow (BM) results in transient expansion of phenotypic and functional HSCs, followed by depletion of HSCs in long-term serial transplants. We find that inhibition of GSK-3 activates both Wnt/β-catenin and mechanistic target of rapamycin (mTOR) signaling in hematopoietic cells. Conditional knockout of *β-catenin* blocks initial HSC expansion in *Gsk-3*-depleted BM, while inhibition of mTOR prevents subsequent HSC depletion. Our working hypothesis is that GSK-3 regulates both self-renewal and differentiation of HSCs by regulating two antagonistic pathways. GSK-3 inhibition of canonical Wnt/β-catenin signaling inhibits HSC self-renewal, while GSK-3 inhibition of mTOR inhibits lineage commitment. Inhibition of GSK-3 activates both β-catenin and mTOR, promoting both self-renewal and lineage commitment pathways. The combination of GSK-3 and mTOR inhibitors may therefore simultaneously suppress the commitment pathway and promote self-renewal in HSCs. In support of this model, we have recently shown that HSCs cultured in serum-free, cytokine-free medium supplemented with both GSK-3 and mTOR inhibitors reconstitute the hematopoietic systems of lethally irradiated mice. This is the first time HSCs have been maintained *ex vivo* in the absence of hematopoietic cytokines. We are now identifying downstream mediators of Wnt/β-catenin and mTOR signaling to define the mechanism by which these pathways regulate HSC homeostasis.

Recent clinical studies have shown that ex-vivo expansion of hematopoietic stem and progenitor cells (HSPC) on mesenchymal stromal cells (MSC) leads to a superior amplification of $CD34^+$ HSPC and can be successfully transplanted. However, to date approaches describing MSC-based expansion of HSPC recruit unmanipulated naïve MSC, while further induction of their HSC-supportive potential can additionally improve outcomes of HSPC expansion. ECM proteins and signalling molecules besides affecting HSPC are capable of modulating gene expression profile of MSC. We suppose that ECM components in combination with signalling proteins can influence HSPC-supportive potential of MSC. Therefore, we aimed at identifying ECM and signalling proteins in a combinatorial fashion in order to screen their potential capability of inducing the expression of HSPC-supportive genes in MSC. For this purpose we initially generated dual-reporter constructs encoding two secreted reporter proteins: Gaussia luciferase under the control of human Angiopoietin-1 (Ang-1) or human stromal cell-derived factor-1 (SDF-1) promoters and secreted alkaline phosphatise (SEAP) under the control of a constitutive promoter to normalize promoter activity. Next, we stably transfected immortalized human bone marrow-derived MSC with Ang-1 and SDF-1 dual-reporter constructs to generate Ang-1 and SDF-1 reporter MSC, respectively. Established high-sensitive secreted dual-reporter systems enabled subsequent continuous monitoring of Ang-1 and SDF-1 gene expression in MSC cultured for 8 days on ECM/signalling protein microarray plates. For the generation of these plates we used an automated workstation to immobilize varying amounts of ECM proteins, namely collagen I, fibronectin, laminin, and vitronectin, alone and in combination with signalling proteins, in particular Jagged-1, N-cadherin, or Wnt3a. Overall more that 100 conditions were available in triplicates on a 384-well plate for each type of reporter MSC. These reporter arrays showed that Ang-1 and SDF-1 expression can be induced by different ECM and morphogen combinations. Thus, fibronectin alone and its combination with all signalling proteins induced the highest level of Ang-1 expression compared to all other conditions, while SDF-1 expression was maximally induced by laminin and its combination with the aforementioned signalling proteins. The most relevant findings of the array experiments could also be

confirmed by quantitative PCR. Furthermore, continuous monitoring of gene expression revealed combinations, in particular with collagen, capable of only short-term induction of gene expression. Taken together, the newly designed dual-reporter array based on transduced MSC allows for high-throughput-screening of ECM and signalling proteins inducing expression of HSC-supporting genes in MSC in a time and dose dependent manner.

MESENCHYMAL STEM CELLS AS GRAFT VERSUS HOST DISEASE PROPHYLAXIS IN TRANSPLANT OF THALASSEMIA MAJOR PATIENTS: AN EXPERIENCE FROM INDIA

Ashis Mukhopadhyay, Jayasri Basak, Soma Mukhopadhyay, Argha Nandy, Ujjal kanti Roy
Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India

Background: Mesenchymal Stem Cells (MSCs) have unique characteristics such immune suppression by inhibiting T cell proliferation and acceleration of hematopoietic stem cell engraftment. Soluble factors and cells are implicated in the MSC-mediated T cell suppression and numerous clinical trials using MSCs to prevent graft-versus-host disease (GVHD) have been reported. MSCs are suggested to suppress acute GVHD without impairing graft-versus-leukemia effects. Our aim is to see the effect of MSCs in GVHD prophylaxis and result of thalassemia major patients.
Material & Method: We selected 10 thalassemia major patients whose umbilical cord blood transplants were performed at bone marrow transplant unit of Netaji Subhas Chandra Bose Cancer Research Institute, Kolkata, India. The age range was 4-15 years (mean 8.5). Sibling cord blood was used as stem cell source. In 5 patients we used routine GVHD prophylaxis (methotraxate, cyclosporine and methlprednisolone). In another 5 patients we added additional cord blood MSCs. MSCs from sibling cord blood were cultured and administered to the recipients at doses of 0.8-1.3×106/kg when the blood count indicated recovery.
Result: GVHD of stage II-IV developed in 4 (80%) out of 5 thalassemia transplants where routine GVHD prophylaxis was used. On the contrary only 1 patient (20%) developed grade III, 1 patient grade II and 3 patients developed grade I GVHD where additional MSC were used as GVHD prophylaxis. There were no difference in the graft rejection rate, chronic GVHD development, or infectious complication. There was no mortality in any of the patients in both the groups. There was a rejection (20%) of the graft in the group where no MSC was used.
Conclusion: We can conclude that MSC can be safe and effective method of GVHD prophylaxis in thalassemia transplants. The number is very small. We intend to continue the programme more in thalassemia transplants as well as in other allogenic transplants.

IN-VIVO SINGLE CELL RNA-SEQ ANALYSIS OF OSTEOLINEAGE CELLS WITHIN THE HSPC NICHE IDENTIFIES INTERLEUKIN-18 AS A NOVEL HEMATOPOIEITIC REGULATOR

Lev Silberstein[1], Peter Kharchenko[2], Masatake Osawa[1], Charles Lin[1], Francois Mercier[1], Youmna Kfoury[1], Christina Lo Celso[3], David T. Scadden[1]
[1]Massachusetts General Hospital, Boston, MA, United States, [2]Harvard Center for Biomedical Informatics, Boston, MA, United States, [3]Imperial College, London, United Kingdom

Despite substantial experimental evidence suggesting that osteolineage cells (OLCs) regulate HSPC behavior, the molecular nature of OLC-HSPC cross-talk remains largely unknown. We hypothesized that OLCs adjacent to transplanted HSPC represent a distinct “niche OLC” population, which is enriched for HSPC-regulating molecules. We set out to define the molecular signature of this population in-vivo by comparative transcriptome analysis of the individual col2.3GFP+ OLCs located proximally (<2 cell diameters) and distally from a single transplanted HSPC.
In order to address this question, we established a novel method of targeted single cell retrieval, which enabled micromanipulator-assisted aspiration of HSPC-proximal and HSPC-distal OLCs into a glass micropipette directly from live unfixed sections of neonatal mouse bone, followed by single cell RNA-Seq analysis.

Our data revealed that HSPC-proximal OLCs had a distinct transcriptional signature, both at the level of top 200 differentially expressed genes and genome-wide, as determined by a blind classifier software. Gene set enrichment analysis showed a significant increase for genes associated with cell migration (p=0.003) and angiogenesis (p=0.008); moreover, a literature-derived “HSPC-niche” gene set (CXCL12, angiopoietin 1, placental growth factor, VCAM-1, IL-7, Wnt-4) was highly upregulated in the HSPC-proximal OLCs (combined p=2.1-10). These data suggest that HSPC-proximal OLCs represent a functionally distinct subset of OLCs with HSPC regulatory function.
We further investigated the role of two individual genes which were preferentially expressed in the HSPC-proximal cells: cell adhesion molecule Embigin (Emb) and proinflammatory cytokine IL18. Using antibodies against Embigin and VCAM-1, we isolated a small (3.4%) subset of Embhigh col2.3GFP+ OLCs from adult mouse bones and found that the Q-PCR profile of these cells recapitulated that of an individually picked single HSPC-proximal OLCs, in particular with regard to quiescence-inducing molecules CXCL12 and angiopoietin-1. In col2.3PPR mice, we found that a 2 -fold reduction in Embhigh col2.3GFP+ OLCs was associated with an increase in proportion of LT-HSCs in G2/S/M phase of cell cycle, indicating that HSCP-proximal cells are involved in control of HSPC quiescence.
Consistent with this observation, we identified IL18 as a novel regulator of HSPC quiescence. Under homeostatic conditions, IL18 KO mice had a decrease in the proportion of HSPCs in the G0 phase of the cell cycle (82% vs 87%), which was associated with a small (1.4-fold) reduction in the frequency of HSPCs in the bone marrow, presumably due to their loss through excessive proliferation. Upon transplantation, IL18-deficient microenvironment conferred significantly faster short-term reconstitution ability to WT bone marrow cells.
We conclude that our approach identified a rare population of OLCs with HSPC niche function and uncovered a previously unknown role of IL18 as a hematopoietic regulator; our data suggest that attenuating IL18 signaling may be clinically relevant in accelerating post-transplantation bone marrow recovery. More generally, our studies established novel experimental approach to the study of heterologous cell interactions and demonstrated - to our knowledge, for the first time - that single cell RNA-Seq assay can be used as a discovery tool for novel mediators of inter-cellular communication.

HIGHLY EFFICIENT AND SCALABLE GENERATION OF FUNCTIONAL ENDOTHELIAL CELLS FROM HUMAN PLURIPOTENT STEM CELLS BY A NOVEL GSK3 INHIBITOR.

Christoph Patsch, Martin Graf, Roberto Iacone
Pharma Research Early Development, Roche, Basel, Switzerland

The use of human pluripotent stem cells (PSCs) for *in vitro* disease-modeling and clinical applications is limited by the ability to rapidly produce pure populations of various cell types in sufficient quantities.
Herein, we describe a scalable monolayer protocol to induce vascular cells in chemically defined conditions driven by a novel and potent GSK3ß inhibitor. Within six days we generated large cell populations that are highly enriched for endothelial cells (VE-Cadherin$^+$ ≥85%). We isolated VE-cadherin$^+$ cells by magnetic activated cell sorting (MACS) to ensure pure and homogenous endothelial cell cultures (≥98%). Time-resolved whole-genome expression and selective qRT-PCR analysis revealed a gene expression pattern closely resembling early embryonic vasculogenesis. Further characterizations of VE-Cadherin$^+$ cells, confirm a functional endothelial phenotype. Stem cell-derived endothelial cells give rise to continuous endothelium with dynamic barrier function properties, form vascular network-like structures in angiogenesis assays, show *in vivo* angiogenic potential, convert into activated endothelium after treatment with pro-inflammatory cytokines, thereby facilitating the recruitment of leukocytes. Overall the purified VE-Cadherin$^+$ cells present an endothelial-specific expression pattern; positive for PECAM-1$^+$, CD34$^+$, VE-Cadherin$^+$, vWF$^+$, CXCR4$^+$, VEGFR2$^+$, VEGFR3$^+$ and negative for the hematopoetic lineage markers CD45$^-$, CD43$^-$ and for the smooth muscle cell markers PDGFRβ$^-$, SMA$^-$ The endothelial cell population maintained their cellular identity over the period of cultivation.

This novel and robust method allowed us to reproducibly generated large numbers of homogenous endothelial cells from more than 20 different PSC lines including disease-specific lines from patients that have vascular complication associated with Type 2 Diabetes. With the growing need for defined protocols, our differentiation system may become the standard for deriving endothelial cells at relevant scales appropriate for drug discovery campaigns and regenerative therapies.
